Display rules play a major role in every culture and society because they aid the regulation of behaviors in social contexts. They allow individuals to engage in normative behaviors prescribed by social roles in specific situations and help to maintain culture-specific meaning of social relationships. Not displaying anger toward one's boss, for instance, helps to ensure that one does not aggress behaviorally toward his or her boss, keeping social hierarchies intact and ensuring that the boss–subordinate relationship stays within culturally prescribed boundaries for appropriateness. The importance of display rules to social regulation may be seen most dramatically, perhaps, when individuals express emotions that violate their culture's display rules; for example, when a person smiles at a funeral or displays anger at a wedding. Display rules work to make sure things like that do not happen, and social interaction is regulated.

How Do Display Rules Work?

Display rules can modify expressions in different ways, depending on the situation. Individuals may learn to express emotions as they are with no modification (i.e., what one sees is what one gets), such as when people are alone or with close friends or family members. Display rules may deamplify an expression, showing less than is actually felt, such as when individuals show their displeasure but not in its entirety to a store clerk in public. In other circumstances, display rules may amplify an expression, showing more than what is felt, such as when subordinates laugh at the boss's not-so-funny jokes. Display rules can neutralize expressions to show nothing (the poker face) or to qualify an expression by displaying it with other emotions that comment on it. Adults often express anger toward children with a smile, for instance, or sadness and distress with a smile toward their friends. In these cases, the smiles

qualify the meaning and interpretation of the anger or sadness. Display rules can mask an expression by concealing it and showing another in its place, such as when individuals smile even though in reality they feel angry or sad. Finally, display rules can encourage individuals to simulate expressions when no emotion is actually felt.

Cultural Similarities and Differences in Display Rules

People of all cultures learn display rules early in life. For example, studies have documented children as young as preschool age masking negative emotions with smiles. Certainly in young childhood—primary school years—children are able to verbalize many of the rules they have learned, demonstrating conscious knowledge of display rules.

There are universal and culture-specific aspects to display rules. For example, people of all cultures probably learn to not display emotions of anger, contempt, or disgust toward higher-status others, especially in public contexts. Thus there is a functional universality of this display rule. Yet people of different cultures also learn different, specific ways of putting this display rule into action. Some cultures, for example, may foster neutralization of one's anger, showing nothing to the boss. Other cultures, however, may foster masking of the anger, showing something else altogether (often a smile). Others may encourage the display of anger toward the boss but at the right time and place and at lower intensity (deamplification). Thus, there are major cultural differences on what may be considered the tactical level of display rules even though there are universal aspects to their functional or operational level.

In fact, there are many functionally universal display rules on the operational level. For example, individuals tend to endorse the greatest emotional displays when alone, then with family and close friends, then with acquaintances, and finally with strangers, and this effect appears to be universal. Emotional exchange appears to be a central component of close relationships; the history, familiarity, and intimacy of these relationships provide individuals with the safety of expressing emotions in a context in which they know how they will be judged.

Accordingly, the management of emotional displays and the perception of one's emotional display management by others are important factors in the start of friendships and other communal relationships.

Display rules also differ according to context and culture. Individuals endorse emotional expression with ingroup others more than when with outgroups, and this difference appears to be universal. But there are also cultural and emotion-specific differences in this ingroup–outgroup difference. Members of individualistic cultures tend to endorse more negative and less positive emotions to ingroups and more positive and less negative emotions to outgroups. Conversely, members of collectivistic cultures tend to endorse the opposite: more positive and less negative emotions toward ingroups and less positive and more negative emotions to outgroups.

When individuals mask or qualify their emotions, they usually do so with smiles. Yet the smile of true enjoyment is behaviorally different than smiles used to mask or qualify emotions. True enjoyment smiles not only involve the smiling muscle (zygomatic major), which pulls the lip corners up, as is characteristic of masking smiles, but also involve the muscle surrounding the eyes (orbicularis oculi), which raises the cheeks and provides the twinkle in the smile. True enjoyment smiles are known as Duchenne smiles, named after the French physiologist who discovered their coupling. (Spontaneous smiles of true enjoyment also involve smooth onset and offset of the facial muscles and symmetry on both the right and left sides.) Other smiles fall into the large category of non-Duchenne smiles. Thus, although smiles are the most commonly used expression to mask or qualify emotions, they are distinguishable behaviorally by whether or not they are Duchenne smiles.

DISSOLUTION OF RELATIONSHIPS, BREAKUP STRATEGIES

The dissolution of a relationship can be considered one of the most painful and stressful events in the life of an individual, with psychological and emotional effects that may extend to the family and social network. With current divorce rates at approximately 50 percent, there is a clear need to learn more about both marital and premarital relationship breakups. This entry describes one specific part of the dissolution process—the strategies that are used to disengage from intimate relationships.

Relationship researchers do not characterize the breakup as a single event but rather as a process that may lead to a change in or the eventual termination of a relationship. Behavioral or communication strategies are considered in most stage models of relationship dissolution. There are several stage models of the process that have been proposed that include the common patterns that a couple may go through. The process typically begins with the realization that one or both partners are dissatisfied with the relationship. Once the decision has been made to act on or to discuss this dissatisfaction, a number of breakup strategies may be used.

Breakup strategies include both verbal and non-verbal methods to disengage from or terminate a relationship. These strategies are considered goal-directed and proactive and are typically examined from the perspective of the initiator. Most breakups are not mutual—in most cases, one partner unilaterally wants to end the relationship more

than the other. It is the initiator who engages in the behavioral and communication strategies that are instrumental in changing or ending the relationship. There are, however, some strategies that have been identified that partners may use when the decision is mutual.

Research focused on understanding more about these strategies and their role in the breakup process has had two primary goals. The first goal has been to identify and classify the particular strategies that individuals use during the dissolution of relationships. A second goal has been to investigate whether the selection of breakup strategies depends on particular factors, including individual attributes (e.g., age, gender), relationship attributes (e.g., the level of intimacy), or situational factors (e.g., marital vs. premarital, amount of overlap in shared social networks).

Classification of Strategies

Researchers have identified numerous breakup strategies by asking individuals to generate or recall methods that they have used to end relationships. Example strategies that have been identified include “openly express the desire to end the relationship”; “avoid contact with my partner”; “reduce displays of affection”; “ask someone else to break the news” and “act unpleasant so that my partner initiates a breakup.” Statistical techniques (e.g., factor analysis, cluster analysis) have been used to determine the commonalities among the various strategies. Research by Michael Cody and colleagues supports the classification of strategies into five general categories: (1) behavioral de-escalation, (2) de-escalation, (3) justification, (4) positive tone, and (5) negative identity management. Research by Leslie Baxter has identified four categories: (1) avoidance/withdrawal, (2) manipulatory, (3) positive tone, and (4) open confrontation.

Baxter suggested that both unilateral (i.e., non-mutual) and bilateral (i.e., mutual) breakup strategies can be described by two underlying dimensions. The first is the *directness* (or indirectness) of the strategy. This dimension describes whether or not the initiator is explicit or unambiguous in stating that the goal is to terminate the relationship. Less direct strategies may not require

such an explicit statement. The second dimension is the degree of other-orientation. Other-oriented strategies show concern and attempt to reduce hurting one's partner. In contrast, self-orientation strategies are done with less consideration for protecting the feelings of one's partner. Examples of strategies will be illustrated with respect to these two dimensions.

Direct strategies include *fait accompli* in which there is a direct, unilateral ending of the relationship by the initiator. Such a strategy can also clearly be classified as more self- than other-oriented because the initiator pronounces the relationship ended with no opportunity for the partner to engage in discussion or negotiation. Another direct strategy has been called the state-of-the-relationship talk. The initiator clearly is concerned about his or her partner, and this strategy has the appearance of being more mutual than it is, allowing the partner to save face.

There are two main strategies that are used when both partners desire a breakup. Attributional conflict, as the name implies, involves each partner blaming the other for causing the end of the relationship. In contrast, a negotiated farewell is direct but far more other-oriented. The discussion may focus on shared blame or external causes and may occur in the context of desired or anticipated future contact (e.g., because of a shared social networks or children).

Less direct strategies include those described as withdrawal-avoidance (e.g., reducing contact, disclosure, or intimacy). Such actions are considered both self-oriented and unilateral, as they may leave the partner feeling confused and hurt. Given the proliferation of new communication technologies, a subcategory of avoidant strategies has emerged that involves avoidance via distant communication (e.g., e-mail, text messaging). Pseudo-de-escalation (i.e., "let's just be friends") is a unilateral decision that hides the intention of exiting the relationship through the desire to redefine it or to reduce the level of intimacy. Because the true intention is not made known, this is a relatively indirect strategy. A manipulatory strategy such as cost-escalation (i.e., acting inconsiderate or unpleasant in the hopes that the partner will initiate the breakup) is also considered an indirect and self-oriented strategy.

Factors Influencing the Choice of Breakup Strategy

A number of studies have identified some of the factors that may influence the choice of particular strategies. Direct strategies are more likely to be selected when a high level of closeness or intimacy existed in the relationship. Moreover, direct strategies are likely to be used if the cause of the dissatisfaction can be characterized as external or if there is the desire to maintain contact. Recent research has shown that different strategies vary in how compassionate they are to the partner being left with certain types of direct, other-oriented strategies that are rated as very compassionate, even though the intent is to end a relationship. External factors (e.g., the need to relocate for school or employment) are associated with the selection of very compassionate strategies, whereas the special case of partner betrayal or infidelity is associated with the least compassionate or other-oriented breakup strategies.

DISSOLUTION OF RELATIONSHIPS, CAUSES

With the current rate of divorce in the United States being approximately 50 percent, not only do the spouses who are divorcing try to understand what caused the dissolution of their relationship but also do social scientists. This entry will examine possible causes of both divorce and the dissolution of other types of romantic relationships. Before doing so, it is important to address several issues pertaining to the causes of relationship dissolution.

Complexities in Determining Causes of Relationship Dissolution

Identifying the cause or the causes of relationship dissolution is a very challenging endeavor for a number of reasons. First, there are important distinctions among what people report to be the cause of their breakup (i.e., the public perspective), what they actually believe to be the cause of their breakup (i.e., the partner perspective), and what may have actually caused the breakup (the researcher perspective). Research has suggested that people who are going through a divorce or dissolution typically create a public story of what happened in their relationship that led to its termination. These stories often present the individual in a positive light, minimizing the individual's role and attributing the dissolution to either one's ex-spouse or ex-partner or to unfortunate circumstances. Thus, these stories may be both incomplete and even inaccurate with respect to how the events surrounding the divorce actually unfolded. In addition, individuals may come to actually believe their stories, even if they were distortions of the truth. For example, partners often divide themselves into the leaver and the person who was left. However, research by Joseph Hopper indicates that it is not a simple matter to determine who was the one to leave and who was left and that individuals often assume these roles even though both parties were dissatisfied with the relationship and both may have been thinking of dissolving the relationship.

In addition, researchers attempt to identify the causes of divorce on a grander scale in the sense that they look for regularities in factors that may

lead to dissolution among people in general. Whereas the partner perspective identifies each individual's view of what caused the dissolution of his or her relationship, the researcher perspective uses empirical investigations to identify factors that seem to account for dissolutions in the general population. Thus, the partner and researcher perspectives have different goals and may reach apparently divergent conclusions. For example, many individuals blame the termination of their relationship on infidelity. However, because many relationships survive instances of infidelity, the researcher perspective suggests that infidelity is seldom the primary cause of dissolution. Each perspective taps a different, but important, aspect of the complex picture of why dissolution occurs.

A second major challenge is that no single cause is likely to be sufficient to explain why dissolution occurred. The challenge is to identify the multiple factors that are causally responsible for the termination of the relationship. Finally, the factors reviewed in this entry do not always lead to relationship dissolution but increase the chances that it will occur.

First, this entry considers individual and relationship factors that contribute to divorce and then it reviews some possible societal factors implicated in high dissolution rates.

Individual and Relationship Factors

Researcher Caryl Rusbult suggested that three factors determine the likelihood that a romantic relationship will terminate. First, when partners are dissatisfied with the relationship, they are more likely to try to end it. Second, when the partners have few resources invested in the relationship, they are more likely to terminate the relationship. Investments include the presence of children, co-owning real estate or personal property, or simply spending considerable time together. Finally, when partners believe that they have high quality alternative relationships available to them, they are more likely to leave their current relationship. For example, if one partner believes that she or he could find a much more supportive and loving partner than her or his current one, she or he is more likely to leave the relationship. The discussion below is organized around these three factors that can contribute to relationship dissolution.

Relationship Satisfaction

Low levels of relationship satisfaction increase the chances of dissolution. Because most relationships begin with both partners having relatively high levels of satisfaction, it is clear that there are factors that erode these high levels of satisfaction in relationships that eventually end in dissolution. First, research suggests that relationship partners who have overly high relationship expectations (e.g., they believe that passion should always remain high) tend to become disappointed as these expectations are not fulfilled, and they become less satisfied over time.

Second, individuals may have certain personality characteristics that led both partners to become less satisfied with the relationship. In particular, neuroticism (i.e., high levels of negative emotions, particularly anxiety) has been identified as a characteristic that often leads the person to feel insecure, anxious, and unsure about how well the relationship is functioning. Equally important, one partner's high level of neuroticism also erodes the other's level of relationship satisfaction. It is difficult to remain satisfied in a relationship when one's partner is frequently anxious, insecure, challenging, and testing of one's fidelity and trust. If both partners are neurotic, even though they may experience some comfort in both having some of the same feelings and thoughts, the negative effects on the relationship may be particularly great.

Other psychological characteristics may contribute to the likelihood of dissolution. Relationships in which one or both of the spouses suffer from a personality disorder, mental disorder, and/or substance abuse all have an increased risk for relationship discord. These psychological challenges can lead to divorce or dissolution by increasing tensions in the relationship and detracting from either or both partner's relationship satisfaction.

Third, relationship satisfaction may diminish due to high levels of conflict. Individuals who come into the relationship with poor conflict management skills have an increased chance of relationship conflict and tension in any of their relationships. There is even evidence that divorce proneness has a genetic component, presumably because there is a genetic component to personality characteristics that increase relationship conflict and that detract from relationship satisfaction.

Fourth, stress from having stepchildren can lower relationship satisfaction. There is evidence that second (and subsequent) marriages are more likely to end in divorce than are first marriages at least partly because of the stresses arising from having stepchildren. The stepparent-stepchild relationship can be quite stressful not only for the stepparent and stepchild but also for the biological parent and siblings.

Finally, many partners report that infidelity was the primary cause of their breakup, presumably in part because it detracts from relationship satisfaction. However, it is also difficult to determine whether the transgression led to the relationship dissatisfaction, whether relationship dissatisfaction led to the transgression, or whether both causal mechanisms are operative. Nevertheless, although research suggests that infidelity by itself is seldom the only cause of dissolution, it clearly contributes to an erosion of relationship satisfaction.

Investments

Investments refer to resources that serve as barriers to ending the romantic relationship. Typical investments include joint ownership of real estate and/or personal property, considerable time spent together as a couple, and a large number of mutual friends. To the extent that couples have made these investments together, their chances of dissolution are reduced.

Another investment that reduces the chances of dissolution is when a couple has its own biological children. Parents typically become more reluctant to break up when they have children because they are fearful of the potential negative consequences on their children. In fact, there is even some evidence that the sex of their children influences decisions to stay together or break up. Couples with at least one boy are less likely to divorce than are couples with only girls, presumably because parents, especially fathers, believe that boys are more vulnerable and because boys are more valued than girls.

Being legally married is also an investment that reduces the chances of dissolution. The institution of marriage is legally recognized in every state and provides married couples with precise provisions and legal recourse in the event that the marriage is dissolved. Cohabiting couples are not afforded this same protection, and in the

event of the dissolution of the relationship, the laws are much less clear regarding what the rights are of each individual in the relationship. Therefore, married spouses have an investment in the institution of marriage that cohabiting partners may not have, an investment which may reduce the chances of dissolution. Not having a marriage certificate may also make it easier to break up from an emotional perspective.

In addition, individuals who are very religious and whose religions strongly discourage divorce face barriers to divorce that less-religious individuals and those with allegiances to religions that are more accepting of divorce do not. Thus, religiosity may serve as an investment that may lessen the chances that either or both spouses will initiate a divorce.

Finally, financial investments decrease the likelihood that couples will dissolve their relationship. When couples have considerable shared assets, such as a house or automobiles, it can be more costly to divorce or break up than when the couple has few assets. In addition, it is less expensive to live together in one household than in two. Finally, if one does not believe that he or she can manage financially on only his or her income, that partner may feel pressure to stay in the relationship.

Relationship Alternatives

Relationship alternatives refer to how easily the partner believes that he or she could find an alternative partner to the present one. Certainly, the factors listed earlier that erode away at relationship satisfaction also would lead one to believe that he or she could possibly obtain a more satisfying alternative partner. In addition, individuals who have more power and independence in the relationship may believe that they have more attractive relationship alternatives. Partners with higher-paying occupations and/or those with substantial savings may feel less tied to the present relationship because they know that they could function well financially outside of the relationship. By contrast, those who believe that they are financially dependent on the partner are likely to be reluctant to explore relationship alternatives outside of the present one. With women having more economic and employment equality than ever before, many women may be disinclined to stay in unsatisfactory relationships because they

are no longer as financially dependent on their partner as they were in the past.

However, the impact of power differentials is not restricted solely to financial resources. Those partners who believe that they can manage well without the current partner because they are psychologically and socially prepared to live on their own may be more likely to end the present relationship.

Another example involves individuals who believe that they are attractive relationship partners (e.g., they are physically attractive, have engaging personalities, and/or are intelligent). These partners may be more likely to consider alternative relationships than would those individuals who believe that they are relatively unattractive relationship partners.

Finally, attractive alternative relationship partners are more accessible than ever before. Never before in history have individuals had more opportunity to communicate and interact with other individuals who may become relationship partners. In particular, the widespread popularity and use of the Internet, as well as matchmaking services that partners may choose to use even though they are presently in a relationship, may present temptations and attractions that increase the chances of meeting individuals whom they perceive to be more attractive than their current partner. Additionally, people are more geographically mobile than ever before, a factor which may further increase the chances of finding and meeting an attractive alternative partner. Therefore, the birth of the personal computer and the increased mobility of society have become factors contributing to the risk of relationship dissolution.

Societal Factors

There are a number of societal factors that may have an influence on the likelihood of dissolution. One of these factors refers to the legal landscape concerning divorce. As recently as 40 years ago, the laws in most states required the spouse filing for divorce to allege, and to be able to prove if necessary, that his or her spouse was at fault for the divorce. Some of the more common allegations were infidelity, physical or emotional abuse, substance abuse, incarceration, and abandonment.

Not only is protracted litigation to substantiate sufficient allegations expensive, but individuals lacking sufficient legal grounds to be granted a divorce often resorted to making up allegations, either with their spouse's consent or at the expense of an otherwise amicable dissolution.

To simplify the process and to take away the need for deception, almost all states have now adopted what are known as no-fault divorce statutes. These statutes do not require any allegation of fault other than a general allegation that the marriage is irretrievably broken. Opponents of no-fault divorce statutes believe that making divorce easier to obtain caused an increase in the divorce rate. However, there is evidence to show that the divorce rate had increased dramatically before the changes in divorce laws. Thus, it appears that the changes in divorce laws were themselves caused at least partly by pressures from the growing number of couples who wanted easier, more truthful, and less litigious avenues toward obtaining a divorce. However, in selected instances, it is still possible that easier legal access to divorce has removed some barriers that previously may have kept unhappy couples married and, therefore, may have contributed to selected divorces.

Another societal factor that may impact couples is the economy. Downturns in the economy may lead to loss of employment or a reduction in wages, both of which place considerable stress on relationships. Even though financial difficulties may also serve as a barrier to leaving a relationship, the stress resulting from these strains, for some couples, may be powerful enough to lead to relationship termination. World events, such as the September 11, 2001, attacks or the war in Iraq may also affect the likelihood of divorce or dissolution because they may add to individuals' stress levels, change people's priorities in life (e.g., life is too short to stay in a dissatisfying relationship), and/or lead to lifestyle changes that negatively impact the relationship.

As a final example, changes over time in societal norms may impact the divorce rate. Partly because it is more common, divorce has become more socially acceptable in the United States and less stigmatized in the last 40 years. This greater social acceptance as a whole may lead some to pursue a divorce when they would not have in earlier eras when a greater stigma was attached to divorce. Related to societal norms is the issue of cultural

world views. Individualistic cultures, like the United States and other Western countries, are more accepting of divorce and/or relationship dissolution than are more collectivist cultures, such as those in Africa and Asia.

Variations in Causes of Dissolution

There is considerable evidence that different groups of individuals vary in terms of the factors leading to dissolution. Among these are the partner's age, sex, and race/ethnicity.

Age

As individuals age, their expectations for romantic relationships are likely to change. Younger, less experienced individuals may have overly high expectations regarding how much passion and intimacy should and will be in their romantic relationships. Their relationship satisfaction may decline if, as is typically the case, passion abates in their relationship. If their satisfaction is sufficiently diminished, they may be more prone to pursue relationship dissolution.

Older individuals may have more practical motivations for being in and staying in romantic relationships, such as financial security and companionship. These partners may understand that passion typically declines over time and armed with these realistic expectations, adjust well to this change in their relationship. However, if their financial well-being is threatened, if they are not having their companionship needs met by their partner, and/or if their partner is not contributing adequately to household and childrearing tasks, they may be more likely to think about and/or to initiate dissolution than would younger partners. On the other hand, older women and women with children may feel that they are less competitive in the relationship market should they leave and, thus, may be less likely to pursue relationship termination.

Sex of Partner

Research has consistently shown that women are more likely to legally file for divorce than are men. However, this does not necessarily mean that women actually initiate the process of separating

and eventually divorcing. Research indicates that it is extremely difficult to determine which partner played which roles as the process unfolded. However, a few patterns are worthy of note. More women than men experience depression and anxiety disorders, so men are more likely to report that their spouse's psychological distress was the cause of their divorce. In contrast, men have a greater propensity for alcoholism, substance abuse, and infidelity, which lead women to be more likely to identify these factors as the cause of their divorce. Again, however, researchers cannot state with any certainty that any or all of these factors are actual causes of the divorce.

Race and Ethnicity

Although research studies have shown that African Americans are more likely to get divorced than any other racial/ethnic group, researchers know little about why this is the case. Some have suggested that African Americans, because single parenthood is more common in their communities and because there are more available women than men in the African-American community, are more accepting of relationship breakup in general and divorce in particular. Some ethnic groups, such as Hispanic Americans, may hold a strong stigma against divorce, believing that marriage is a lifetime commitment and that divorce is a violation against the family.

Conclusions

As stated earlier, it is difficult to determine with precision why a relationship ends in divorce or dissolution. In future research, scholars need to work at both the micro- and macrolevels. At the microlevel, researchers need to conduct intensive interviews with partners, ideally both during the dissolution process as well as after it, to understand the meanings they attach to various relationship events and how these events led to the breakup. At the macrolevel, researchers need to study large groups of nationally representative samples of dissolving couples to identify factors that seem to be causally related to relationship termination in the future. At both levels, longitudinal research that studies individuals and couples multiple times over an extended period is necessary. Through this multifaceted approach,

researchers can hopefully gain a better understanding of what researchers have identified as the partner, public, and researcher perspectives on the causes of dissolution.

DISSOLUTION OF RELATIONSHIPS, COPING AND AFTERMATH

The emotional landscape of a romantic separation is vast and complex. For some people, the end of

a relationship is a high point, a moment of relief and newfound freedom that is demarcated by the courage to stand up and end that which was bad. For other people, a breakup hurts in the worst possible ways; loneliness, emptiness, and depression can be fixtures of even the most normative of grief responses. Over time, most people in this situation recover well and regain their normal levels of functioning. For still others, though, grief responses can be much more protracted, evolving into depressive episodes or precipitating problems with substance abuse. In these cases, the breakup can exert a lasting negative toll on one's overall mental health and life satisfaction. This entry reviews research on the psychological consequences of romantic breakup experiences as well as research on the moderators and mediators of adult breakup adjustment, which are explained in detail below. The analysis focuses on the known mechanisms of successful recovery from a breakup and discusses who fares well or poorly in the aftermath of a separation experience. Although there are obvious differences between a nonmarital separation and a divorce (especially when children are involved), both topics are considered here largely because it is expected that coping responses to these experiences differ in quantity more than in kind.

The Consequences of Romantic Separations

This review begins with an important question: Do romantic separations lead to increases in psychological distress? The short answer is yes, but a longer and more detailed analysis suggests that many of the putative consequences of a breakup experience may be causes of the separation itself. Several studies indicate that the psychological problems commonly associated with marital separation (e.g., depression, substance use and abuse, decreases in life satisfaction) predate the divorce and sometimes even the marriage. These findings hold true for nonmarital breakups as well, but the evidence remains mixed, with some research demonstrating that high levels of depression (among those who break up) existed before the separation and other studies showing that depression is a distinct consequence of the end of a relationship. These selection-causation effects may differ depending on the outcomes of interest. Evidence

indicates that problems of substance abuse, including diagnosable substance use disorders, increase in the wake of a separation. Perhaps the strongest evidence for the causal effect of romantic separations comes from genetically controlled studies of twins discordant for mood disorders. Given that monozygotic twins have an identical genotype, differences in life events are presumed to be causal agents in the onset of psychopathology when the twins are discordant for a particular psychological profile. In twins discordant for major depression, marital separations yield a raw risk of 21.6 percent for the onset of a major depressive episode in the first month after the event, which suggests a strong causal effect from divorce to a depressive episode. (This finding, unfortunately, says little about subclinical experiences such as loneliness, longing, generalized dysphoria and sadness, and loss of satisfaction with life, which are among the most commonly described consequences of a separation experience.) Overall, there is clear evidence that negative psychological states can both select people out of marriage and emerge as a specific consequence of the separation experience.

Integrating the Mind and the Body

A small but growing body of evidence suggests that romantic separations can have deleterious effects on physical health outcomes. Although epidemiological studies show clear associations between divorce and physical illness, the psychological correlates of these associations remain poorly understood. For instance, women experiencing a stressful marital separation have elevated levels of evening cortisol and urinary testosterone relative to their married counterparts. Evidence also indicates that among divorced adults, continued attachment to a former spouse is associated with worse immunological outcomes. More research is needed to understand how psychological variables play a role in maintaining, attenuating, or consistently reactivating potentially harmful biological stress response.

Understudied Outcomes of Interest and Populations

With the exception of the health outcome literature described above, most published reports of

nonmarital and marital separation adjustment rely solely on participants' reports of their subjective mood states. This is a clear limitation of the existing literature, and there is much that can be gained by moving beyond the assessment of subjective mood states. Combining reports of subjective experience with the methodologies of cognitive science, informant ratings (such as a friend's report), psychophysiological methods, and/or behavioral samples (such as natural language use) seem likely to provide a more nuanced account of individual differences in emotional recovery. Certain groups of people are understudied as well. Little is known about how breakups impact adolescents, and a great deal of research remains to be conducted on the end of homosexual relationships, as well as with other cultural groups and subgroups.

Resilience Is the Norm, Not the Exception

Most people ultimately fare well following a separation experience. By 2 years after a divorce, many adults report having used the window of change as opportunity for growth, transformation, and personal discovery. Two primary pathways are proposed for understanding the ways in which individuals may flourish following the end of a relationship. The first is a stress-relief pathway in which separation experiences relieve the stress of an unhappy marriage; the second is a crisis-growth pathway in which the challenges of the relationship upheaval provide a critical window for personal growth. Growth and resilience frameworks call for greater emphasis on the positive outcomes of dissolution experiences; indeed, breakups may hold a unique position among stressful life events—they are among the strongest and the most systematic precipitants of emotional distress, but they may also provide some of life's most critical openings for rejuvenation and growth.

The Moderators and Mediators of Separation Adjustment

Moderators of separation adjustment are variables that increase risk for or protect against poor outcomes following separation experiences. Moderators are usually static variables such as gender, demographics (including demographics

specific to the separation, such as whether a person initiated the separation or was left by his or her partner), personality factors, and the availability of social support. In contrast, mediators of breakup separation are the specific-proximal psychological variables that may explain the association between relationship dissolution and subsequent mental health outcomes; although it is clear that mediators of interest may themselves represent important outcomes (e.g., meaning making, one's sense of self-identity), these psychological variables are considered the best targets for experimental interventions and treatments aimed at promoting positive adjustment.

The Moderators

Moderators of separation adjustment get most of the attention in the research literature, and several findings are noteworthy. First, the literature is mixed on gender differences after separation experiences. Relative to women, men tend to report more emotional distress and greater health problems in the wake of a divorce, and it is theorized—although never proven empirically—that this effect is due to the loss of women's protective buffering. In marriage, women tend to monitor men's health behaviors and encourage them to eat better, sleep more, and drink and smoke less. When relationships dissolve, men tend to engage in many more unhealthy behaviors. At the same time, however, women are more likely to become depressed after a separation experience, and this is especially so in situations where negative economic changes are large and persistent. Women suffer a much greater economic toll in divorce than men, and financial instability can be a strong precipitant. Second, initiator status plays a strong role in separation adjustment. People who feel left or dumped by a partner are more likely to report ongoing emotional difficulties in the months after a separation. This does not mean that the experience of initiating or leaving a relationship is an easy one. Initiators often experience guilt and periods of sadness, but these emotions typically predate the decision to end the relationship.

A third moderator of interest is attachment style. Attachment styles refer to people's mental models of relationships—how people typically see themselves acting toward close others and how

they see close others acting toward them. Attachment styles vary along two main dimensions, anxiety and avoidance, with each dimension playing a role in how people regulate emotions. Numerous studies indicate that adults high in attachment security (i.e., those persons low in anxiety and avoidance) evidence the fastest course of recovery following a separation. It is presumed that highly secure individuals view themselves as worthy of future love and view others as worthy of providing love to them, even though the most recent relationship ended disagreeably. In contrast, adults high in either anxiety or avoidance tend to show more persistent patterns of distress; this is especially so for people who are high in anxiety and low in avoidance, which results in a preoccupied attachment style that is associated with frequent bids for reunion with an ex-partner and prolonged states of mourning and distress. Like other moderators, attachment styles merely confer risk or protection against postbreakup distress. Fourth, contact with one's ex-partner has emerged as an important moderator of separation adjustment. A small group of studies have demonstrated that having contact with one's ex-partner increases sadness and anger in the wake of a nonmarital separation experience. In this sense, contact is a moderator because it increases the likelihood of subsequent distress and slows trajectories of recovery over time. It is not clear, however, if the immediate reports of sadness and anger (following contact) are associated with maintained distress or more positive long-term outcomes, such as creating meaning of the event or working toward forgiveness; presently, only the short-term effects of contact are known. This topic requires much more research, especially in light of joint custody arrangements and postdivorce family life.

The Mediators

What is it that changes as people move from feeling distressed about their separation to feeling more calm and organized? When people receive social support, what benefits are conferred by these interpersonal connections? Both of these questions center on the proximal, psychological variables that promote or hinder adaptive change. As relationships dissolve, many adults experience a sense of mental confusion, disbelief, apprehension,

and a loss of hope for the future. Creating a restored sense of cognitive organization is a critical emotion regulatory task for coming to terms with a dissolution experience; from this perspective, the mediators of breakup adjustment can be regarded as appraisal strategies that people invoke to understand and control their emotional experiences. The available evidence indicates that two broad classes of cognitive-emotional mediators explain breakup adjustment: cognitive organization-meaning making and nonacceptance-rumination.

Cognitive Organization and Meaning Making

A great deal of writing suggests that the creation of a coherent, meaningful narrative about one's separation experience is a critical task for successful adjustment. From this perspective, coping and social support help people create acceptable accounts, which provide psychological structure to the event and a more positive outlook of the future. Although only a few studies have tested these ideas empirically, evidence does indicate that people who report better breakup adjustment are more likely to describe (separation) stories that make sense, hang together, are structured in an organized manner, and include detailed examples. Recent studies have begun investigating natural language use as the process through which narratives are communicated to others. In a recent study, relative to men and women coping poorly with a breakup, women coping well talked more about their social networks, used greater linguistic certainty, and used fewer third-person references. The latter finding suggests that well-adjusted women use fewer other-focused words when discussing their separation experience, a tendency which may reflect less psychological preoccupation with one's ex-partner.

Conceptually similar to meaning making, forgiveness is an appraisal-based coping strategy that involves letting go of negative thoughts toward a wrongdoing and in some instances, responding positively toward a transgressor. Within intact relationships, forgiveness toward a partner following an infidelity is associated with a decreased probability of a subsequent breakup. Following divorce, positive forgiveness (i.e., wishing for good things toward an ex-partner) is associated with greater emotional well-being, and the presence of

negative forgiveness (i.e., not feeling vengeful toward an ex-partner) is associated with less depression and less state and trait anger. In a relatively large treatment study; however, forgiveness did not lead to clear improvements in mental health outcomes. Thus, to date, correlational evidence indicates that greater forgiveness is associated with positive outcomes following a separation experience, but experimental interventions have not yet discovered how to teach forgiveness as a way that promotes divorce adjustment.

In addition to meaning making and forgiveness, recent evidence indicates that people's sense of self-identity is closely tied to their breakup adjustment. Much of self-identity—that is, answers to the question, “Who am I?”—is embedded in close relationships, and when love relationships dissolve people are often left with the sense that the essence of their personal identity has dissolved as well. The loss of self-identity clarity was a major feature of Robert Weiss's (1975) qualitative accounts of divorce adjustment, which was among the first systematic study of postdivorce emotional adjustment. Recent evidence suggests that the end of a positive dating relationship is associated with substantial changes in one's self-concept. This finding is important because other work has shown that the degree of identity loss following dissolution is positively associated with feelings of sadness and loneliness. Furthermore, the end of a poor quality relationship is associated with greater personal growth, and this association is statistically mediated by greater rediscovery of the self, more positive emotions, and less loss of the self.

Nonacceptance and Rumination

Evidence indicates that a class of perseverative coping behaviors forecasts poor emotional adjustment. Nonacceptance (which involves longing, disbelief, continued attachment to an ex-partner) and rumination (which involves persistent attention to how bad one feels) are described as a class of coping behaviors because both processes involve repetitive preoccupation, either with the ex-partner or with how bad one feels; although nonacceptance may be more closely related to separation experiences, rumination is characteristic of many depressive episodes and is important for understanding loss responses.

A high degree of nonacceptance (at the end of a relationship) is associated with poor mental health outcomes in both marital and nonmarital samples. Following a nonmarital separation, nonacceptance fully mediated the association between attachment security and sadness recovery; in one prospective study, young adults low in attachment security evidenced longer times until complete sadness recovery, and this association was accounted for by ongoing feelings of disbelief, pining for the ex-partner, and hope for reunion. Nonacceptance is strongly associated with divorce adjustment, both in the short- and long-term. Evidence indicates that up to 12 years after a divorce, adults who remained nonaccepting of the initial separation tended to report more depression. Of course, the direction of this effect remains in question, but it is clear that longing, disbelief, and ongoing attachment to a former partner are associated with greater emotional distress after a separation. As described earlier in this entry, high nonacceptance also is associated with weaker immunological responses after a divorce.

Relative to the study of nonacceptance, fewer investigations have addressed rumination following a breakup. In a large sample of young adults experiencing a breakup, brooding and negative regret were associated with negative adjustment and less positive signs of coping. Interestingly, research on this topic also indicates that reflection, which may be an adaptive form of trying to understand an experience and put it to rest, was associated with positive emotional outcomes. This finding is consistent with work on ironic processes, work which suggests that maladaptive behaviors (including psychological acts) often begin with well-intentioned efforts to understand and solve the problem of negative affect; efforts to reduce negative emotional states become ironic when they unintentionally maintain distress, as in the case of rumination or ongoing pining. It will be informative for future research to understand when, why, and how reflection about a breakup spills over into rumination and regret.

Concluding Remarks and Future Directions

Both the nonmarital breakup and divorce literatures are hampered by a reliance on correlational

methods. Consequently, although many potential mediators of adjustment exist, few have been identified as truly causal. For example, does creating a meaningful and coherent account of one's divorce lead to improved emotional adjustment or follow from it? To answer this question and others like it, experiments that target specific mechanisms (e.g., increasing people's narrative coherence of the separation experience) are needed. In the nonmarital breakup literature, there exists only a single experiment studying the mechanisms of separation adjustment and only a handful of treatment studies exist in the divorce literature. No other work has targeted specific mechanisms of change in a theoretically driven way. To advance the understanding of separation adjustment (and ultimately, to promote positive outcomes), research of this kind will be increasingly important in the next decade of study.

DISSOLUTION OF RELATIONSHIPS, PROCESSES

“Breaking up is hard to do,” according to a song by Neil Sedaka. Though Sedaka may make a seemingly obvious point, he and the countless other songwriters who manage to put words and melodies to the experience of relationship breakup are clearly on to something. Songs about relationships, and especially their endings, land at the top of music charts for two very simple reasons—humans are relational creatures, and interpersonal relationships often end. For these same reasons, the ending of relationships has occupied an important place in interpersonal relationship research since the late 1970s and early 1980s.

What Sedaka did not take note of in his anthem to relationship dissolution is the fact that breaking up is hard to research. Given the ethical constraints that deny researchers the choice of random assignment to partners at the start of relationships, research has typically dealt only with partners who are known to have been in already broken relationships or else are asked to imagine what that would be like, and only recently have longitudinal studies been attempted. Data from most available research are either retrospective or imaginative, and this allows participants to put their stories into

an orderly report irrespective of what might actually have happened in the process of breakup. This can lead to the reports of breakup being rationalized or stripped of some of the complexity that they most likely deserve.

Given this proviso, there have been many explanations offered by researchers about the causes of, stages of, and processes of what has been termed relational dissolution, termination, disengagement, and deterioration, but capturing and generalizing about this phenomenon has proven somewhat challenging due to the dynamic nature of relationship change and negotiation, as well as limitations of research methods. Although most research and literature focuses on romantic relationships, there is distinct research that delineates the disengagement processes of marriages, friendships, and dating relationships separately. This entry gives a modest overview of that research, showing the various ways relational scholars have attempted to characterize the nature of relationship dissolution across and within relational types.

Causes of Relationship Dissolution

As most know from experience, relationships end for a variety of reasons. Sometimes they end suddenly due to a particular event, whereas other times they end more gradually due to a deterioration of feelings and communication. The processes of relationship dissolution may differ depending on relational type. For example, friendships are voluntary nonexclusive relationships that require active effort to maintain and do not necessarily require a declaration of dissolution to end. Often, friendships are simply allowed to wither away due to decreased time spent together and communication in general, that is, calls or text messages cease or are not returned, plans are not made, and so on until no active relationship exists. Of course, some friendships do end more suddenly due to some event (e.g., betrayal).

For marital and dating relationships, which are expected to be exclusive, monogamous and serial, dissolution may be more complicated, or at least more formal. Typically, at least one party will make a declaration that the relationship has ended, though it may not always be the case in relatively short-term and uninvolved dating relationships

(which may dissolve more like many friendships do). Researchers have identified several potential causes for disengagement in romantic relationships such as conflict and negativity, lack of time for relational investment, unsatisfactory or incompatible change or growth of partners, violations of expectations of partner behavior, and one or both partners' romantic involvement with another party.

Theories generated in psychology have been applied to relationships to help explain the process that partners go through when determining whether or not to stay in a relationship (either romantic or friendship). Two social exchange theories that focus on the value placed on the relationship by each partner are called Interdependence Theory, proposed by John Thibaut and Harold Kelley, and Equity Theory proposed by Elaine Hatfield [Walster]. These theories claim that relational partners weigh the costs, or investments they make to relationships, and compare them to the rewards that they receive from the relationships in return and are intent on maximizing rewards while minimizing costs. Interdependence Theory says that partners evaluate their relational outcomes by comparing the costs and rewards to their expectations of costs and rewards, as well as to other relational options they perceive to be available to them (e.g., a different romantic partner or no relationship at all). Equity Theory makes similar claims but allows for equitable relationships rather than an equal relationship assumed by other social exchange models. That is, if partners perceive that their own rewards are proportionate to their input and the two partners are making about comparable inputs for their rewards, then a relationship is equitable, even if it is not equal (one partner could work hard and get more, one partner could work less and get less, and yet both would still feel that the relationship was fair). When the relationship is perceived as inequitable, negotiation may be required to restore equity. Partners may make decisions about dissolution based on what they perceive to be the optimal situation that yields maximum rewards in relation to costs (in Exchange and Interdependence Theory) or fair and equitable outcomes (in Equity Theory). So if these theories are accurate, a potential cause of relationship dissolution for both romantic partners and friends may be simply that the relationship just is not worth the effort required or is not providing fairly balanced outcomes relative to each partner's input.

Strategies of Accomplishing Dissolution

Once the decision to terminate a relationship is made, the deciding partner must devise a strategy for accomplishing said goal. Most people know from experience (whether on the giving or receiving end) that delivering this news is not always easy, and at times, dissolution is complex, requiring multiple strategic moves instead of a simple conversation. Curious about the way termination is accomplished, some researchers have looked for the strategies used by partners to end relationships. Leslie Baxter first looked at strategies used to disengage friendships and found several strategies, which varied on dimensions of directness versus indirectness and self orientation versus other orientation. In line with Baxter's work, Michael Cody found five strategies used to terminate romantic relationships: (1) behavioral de-escalation, which involved avoidance and withdrawal; (2) de-escalation, which involved explaining advantages of termination and regret over termination sometimes with hints of possible reconciliation; (3) justification, which involved giving clear reasons for the termination; (4) positive tone, which involved consideration of the feelings of the other; and (5) negative identity management, which involved lack of explanation and consideration for the partners' feelings or face. Later, Baxter and colleagues looked at romantic relationships and again found that directness-indirectness was an important aspect of strategy (but that greater intimacy decreased the likelihood that withdrawal and avoidance would be used), that partners usually perceived themselves to be more direct than they perceived their partners to be, and that one-sided breakups tended to be more direct than mutual breakups. They also found that mutual breakups were more indirect (for both parties) and produced both more positive reactions to termination and fewer regrets about the nature of termination.

The above strategies describe those felt to be put into action by initiators of dissolution, but do the noninitiators employ strategies of their own? Recent research has shown that marital partners on the receiving end of attempted termination do report employment of strategies of disengagement resistance. The resistance strategy reported to be used most often was called commitment and

entailed the manipulation of love, care, affection, and obligations of commitment. Another reported resistance strategy was alignment, which seemed to be an attempt by the noninitiator to be perceived as a bonded couple (by the initiator and other people). A third resistance strategy was called negativity and was described as an attempt to make a relationship more equitable by heightening positive attributes of the noninitiator or accentuating negative characteristics of the partner. The last and least often reported strategy was called karm and entailed using violence against competitors or relationship rivals.

Mapping Relational Dissolution

Many scholars have proposed what are called stage models of relationship dissolution in attempts to outline different stages that relationships go through during disengagement. Stage model approaches are appealing in their simplicity, but like the participants' reports upon which they are based, they sometimes fail to account for the complex process of dissolution. The following models are general maps of dissolution, but do not capture the dynamic and often ambivalent nature of relationship endings.

Distinctions have been made between marital dissolution and other romantic relationship dissolution. Marital relationship dissolution may be more complicated due to social constraints of stigma, religious affiliation, economic interdependence, and the existence of children, not to mention the legal processes required for divorce. Paul Bohannon characterized divorce as a process that spouses report experiencing in six different stations. The first station, emotional divorce, involves a distancing of partners in emotional and social realms. This distancing and realization of potential end may cause partners to grieve over the lost relationship. The station of legal divorce is just as it sounds—spouses file for a divorce, which is carried out through the legal system. In the midst of the legal divorce, divorcing spouses may experience an economic divorce as well as a coparental divorce (if children are present). In the economic station, spouses divide marital assets and negotiate alimony and/or child support. The coparental station involves negotiations over primary caregiving of

children and other custody arrangements, as well as adjusting to those arrangements. The fifth station, community divorce, involves the reconfiguring of social networks that can involve the loss of certain family and friends that were gained through or during the marriage. The final station, psychic divorce, occurs when the ex-spouses report having separated themselves from the other person both in terms of identity and influence.

Although some models, such as Bohannon's, focused on the process of divorces specifically, others examined the process of relational disengagement more generally. Steve Duck claimed that although levels of commitment, interdependence, and barriers may differ, the basic elements of the termination process are perceived to be the same across various types of romantic relationships. Models that included a broader approach to relational dissolution include Irwin Altman and Dalmas Taylor's model of depenetration, Mark Knapp and Anita Vangelisti's stages of relational breakdown, George Levinger's ABCDE model of relational development and dissolution, Duck's model of relationship dissolution, Loren Lee's model of five critical events, and Leslie Baxter's flow chart of relational dissolution trajectories. Although these models share some common characteristics, each makes its own claims about what the stages of dissolution entail.

Altman and Taylor's early model was simply a reversal of their model of relationship development, which focused on the amount and type of self-disclosure between partners. According to this model, partners develop relationships by increasing the depth and breadth of self-disclosures and achieve relational disengagement in the opposite manner—by communicating in superficial, non-intimate ways until the relationship unravels. Somewhat similarly, Levinger extended models of relational attraction to include relational disengagement. His ABCDE model stands for acquaintanceship, buildup, continuation, deterioration, and ending. One important move that Levinger made was to consider the internal and external factors that constrain relationship termination, such as routine and emotion (internal) and religion and social networks (external).

Another model of dissolution connected to one of development is the Knapp and Vangelisti model of relational breakdown. These scholars outlined

five stages focusing on the type of communication that occurs during each stage: differentiating (partners begin focusing on differences and disengage joint identity), circumscribing (partners no longer communicate frequently or about personal matters), stagnating (interaction comes to a standstill), avoiding (partners avoid face to face communication or physical copresence altogether), and terminating (terms of dissolution are negotiated and breakup is declared).

One model that seems to apply to both romantic relationships and friendships is one that Duck first proposed in the early 1980s and then recently revised with colleague Stephanie Rollie. Rollie and Duck offered six phases for dissolution that encompass both communication and cognition about disengagement: breakdown processes, intrapsychic processes, dyadic processes, social processes, grave dressing processes, and resurrection. During breakdown, one or both partners become dissatisfied with the relationship. If one person reaches the point where the discontent is unbearable, that person enters the intrapsychic process. Here, the individual ruminates about the partner and the relationship, the costs of termination, and the potential rewards of alternative relationships. The individual contemplates disclosure of dissatisfaction to the relational partner but usually represses it. Eventually, the person may reach the point where ending the relationship seems justified.

If this happens, the relationship reaches dyadic processes, where a decision is made about confrontation or avoidance. This usually results in talks about the relationship, where conflict and/or negotiation can occur. If there is a possibility to repair the relationship, this is the opportunity for partners to do so. If there is no room for or attempt at repair, one or both partners may reach another threshold and decide to terminate. Then, the dyad moves into social processes where social network members are told about relational problems. If the partners continue toward termination, the dyad enters grave dressing processes, where partners engage in adjustment behaviors. Here, partners make attributions about relational issues and give separate accounts of the breakup to their social networks. Finally, the resurrection process is where each person readies him- or herself for a different kind of relational life.

Lee's model of dissolution focuses on five critical events or stages in the relational dissolution that are fairly similar to the stages discussed in Duck's model: discovery of dissatisfaction stage, exposure stage (dissatisfaction is discussed), negotiation stage (relationships issues are discussed), resolution stage (decision is discussed), and the transformation stage (discontinuation or relational redefinition). Lee also defines three parameters that influence the nature of dissolution: the operator, referring to the partner who acts as an agent of relational change; the content, referring to the communicative substance of each phase; and the latency, referring to length of time between stages and the overall dissolution process.

In an effort to represent the nuanced and complex processes of relational disengagement, Baxter took a somewhat different approach in creating her map of relational dissolution by using a flow chart instead of a traditional stage model. The flow chart includes various choice points and consequent relational trajectories that Baxter described as the critical features of the relational dissolution process: the gradual versus sudden onset of relational problems, the unilateral versus bilateral desire to exit the relationship, the use of direct versus indirect actions to accomplish the dissolution, the rapid versus protracted nature of the disengagement negotiation, the presence versus absence of relationship repair attempts, and the final outcome of relationship of relationship termination versus relationship continuation. The chart includes various options that partners might choose at different relational junctures and therefore does not characterize every relationship as dissolving in the same way.

Concluding Remarks

Understanding the process of relationship dissolution is a key component to understanding how people relate more generally. Although this entry gave a short overview of the research literature that exists on dissolution, there is much that was not covered. Other relevant research on relationship dissolution has looked at such aspects as how individuals cope with dissolution, the revealing nature of dissolution narratives and individuals'

adjustment to breakups, how dissolution operates in long-distance relationships, and turning points in dissolution between friends. The research presented in this entry provides a look into potential causes of relationship dissolution, strategies individuals use to accomplish dissolution, and what dissolution looks like when broken down into stages. It is doubtful that research focused on dissolution will cease any time in the foreseeable future, given its salience to the emotional and social state of individuals. Relationship dissolution seems to be an unavoidable constituent of relational life—without breakups, there surely would be less to sing about!

DIVISION OF LABOR IN HOUSEHOLDS

The division of household labor involves the allocation of chores among members of a family or household. Household chores include those tasks that are considered necessary to the function of the household and encompass activities such as cooking, cleaning, doing laundry, mowing grass, and other such tasks. As the total sum of household labor required by any given household typically exceeds the ability of one person to complete them all, chores are commonly allocated among various household members. Understandably, this allocation process and the ensuing patterns of chore performance are not always equally shared among family and household members. Both historically and in the contemporary regard, the division of

household chores has been along traditionally gendered lines. This entry discusses the division of household labor and the explanations for the patterns of chore allocation that have been recognized by researchers.

Conceptualization and Measurement

In most industrialized nations, the division of household labor is often regarded as one of the most intransigent qualities of family life. In conjunction with traditional gender roles, the domain of the paid labor force has often been regarded as men's work, while the performance of chores within the home has typically been considered to be women's work. Although it is not necessarily made explicit within societies, most cultures maintain an expectation that women should bear the brunt of responsibility for the performance of household labor. This decidedly gendered pattern of the division of household labor has been examined by researchers for decades and has shown little evidence of change. In recent history, there has been considerable change in the participation of women in the paid labor force, along with substantial increases in the percentages of women obtaining a college education. These particular changes have been associated with slight variations in the overall allocation of chores; women are now performing less, yet these changes by no means approach a level of equity or equality in the division of household labor.

Household labor has been assessed by researchers in a variety of manners, such as by the use of large national surveys, self-maintained time dairies, and retrospective interviews. Each of these methods offers its own advantages, and the practical assessment of the division of household chores largely depends upon whether the researcher intends to pursue either a quantitative or qualitative measurement. In conceptualization, though, the division of household labor is typically regarded as having three basic forms.

The first, and most obvious, conceptualization addresses the amounts of absolute time that each individual allocates to the performance of chores around the home. Since the division of chores implies that each person will have to commit some of his or her time (e.g., daily, weekly) to executing

the tasks, it is necessary to make relative comparisons of the total amounts of tasks that are performed. This comparison in and of itself provides a good indication of how chores are being divided in a given household. However, since the nature of the division of household labor involves head-to-head comparisons of effort, the absolute total contributions of each person may not adequately exemplify the allocation processes. A second and equally useful conceptualization is the relative share of the total labor in a given household performed by each person in the home. This conceptualization allows for a more precise appraisal of the division of labor given that it focuses not on individual totals but rather more exactly on how much each person does relative to others. Since household members will typically compare their chore performance to others, this conceptualization makes logical sense. Finally, it is also necessary to recognize not just the total amounts and relative shares of household labor that each person performs but also the kinds of chores that each person does. It is conceivable, for example, that a husband and wife perform exactly the same total amounts of labor around the home, yet each performs a unique set of tasks (e.g., a wife does all of the cooking and cleaning, while the husband does all of the yard work and laundry). Hence, the third conceptualization of the division of household labor involves how specific chores are segregated among the members of the household.

Patterns of Household Labor Allocation

Across numerous studies, both in the United States and in other countries, the division of labor among adults has consistently been shown to be quite skewed; women perform the vast majority of chores. Although the total amounts of labor vary somewhat from one study to another, women are typically shown to perform between 32 to 38 hours of household labor each week (not including time spent in childcare). Men's contributions on average are considerably less, with most reports revealing a total anywhere between 12 to 18 hours of housework each week. In the absolute, then, women typically perform approximately twice as much household labor as men. In the relative comparison of men's and women's

contributions, there is simply no semblance of equity within the typical allocation of household chores.

Furthermore, research that has focused more precisely on the segregation of chores commonly notes that the individual tasks of men and women are quite distinct. Women tend to exert the majority of their total time performing traditional chores, such as cooking, cleaning, and laundry tasks. Men, on the other hand, tend to spend the majority of their time performing chores that take them outside the home, such as yard work, home repairs, and automobile maintenance. It is this highly segregated nature of the division of household labor that leads many researchers to conclude that traditional gender roles continue to influence couples and families in meaningful and tangible manners.

Beyond the quantitative dimensions of the division of household labor, there are also several qualitative traits that should be recognized. Women, for example, are spending the larger portion of their contributions performing chores such as cooking and washing dishes. Such chores have a regimented quality about them, as they have to be performed daily and at specific times of the day. Men, who are more likely to perform chores such as mowing the yard or washing the car are able to pick and choose the day and time when they perform such tasks, thus allowing them great flexibility and control over the timing of their chores. Researchers have also suggested that the chores predominately performed by each sex will also yield different intrinsic rewards to women and men. Distasteful chores, such as the scrubbing of a toilet bowl, are more likely to be performed by women. These sorts of chores are onerous, demanding, and offer little intrinsic satisfaction for women. However, researchers have noted that men are often able to reap such intrinsic rewards from many of their typical chores (e.g., auto care), particularly as these chores may allow them to demonstrate their masculinity to others.

Explaining the Division of Household Labor

Researchers have long noted the disparities between the household labor contributions of women and men. There remains, though, the necessary question

of why chores are divided in such ways. Although a wide variety of theories have been offered across multiple social science disciplines as explanations of the division of labor, most fit within three broad perspectives. The first, which is based upon the relative resources that each person has, argues that the division of household chores inescapably comes down to the issue of power within marital and family relationships. Relative resource theories make several basic assumptions about the nature of housework and interpersonal relationships. Specifically, household labor is envisioned as being a set of onerous and undesirable chores. However, inasmuch as the chores must be performed, the allocation of chores is ultimately decided by the person who wields the greater power in the household. Power is derived from having the larger amount of human resources (e.g., employment, income) relative to that of other household members. Given that chores are considered to be undesirable, this theoretical perspective contends that the person with the greater power and authority will designate others to perform more chores than themselves. Although this makes intuitive sense, researchers have noted that power-based explanations are not often supported in their studies. For example, even with the substantial increases in women's labor force participation, the division of labor among dual-earner couples is shown to be similar to that of single-earner couples, wherein the husband is employed and the wife is not. Although power, as based upon relative resources, does appear to have some influence on the overall division of household labor, its impact is meager at best.

A second theoretical perspective is one based primarily on the rational choice of family members. In this explanation, the allocation of chores results from a simple consideration of which person has the greater amount of time available to perform the chores. Time availability, then, becomes the core component of any decisions regarding the division of chores. If a spouse is employed outside the home, for example, he or she will have less available time to do housework. Of course, this perspective assumes that spouses largely disregard gendered expectations concerning specific chores and that they simply perform chores on the basis of having sufficient time to do so. As with relative resource theories, this perspective seems logical

but has received little support among researchers. Comparisons of the paid labor hours and work schedules among dual-earner couples, for instance, have shown little effect upon the division of chores among wives and husbands.

Finally, a third perspective that has been posited by researchers involves socialization and gender ideologies. Many have proposed that the seemingly intransigent nature of the division of labor over time is the result of the intergenerational transmission of traditional gender roles. Through exposure to both the direct and indirect influence of their parents and other family members, individuals learn and internalize traditional gender roles. Specifically, over their childhood and adolescent years, individuals will view their parents performing certain gender-typed household chores. Likewise, parents will assign particular chores to their children, largely on the basis of the sex of the child. This long and sometimes subtle learning process results in the acceptance of traditional gendered expectations concerning the allocation of chores around the home. Of the three theoretical perspectives on the division of household labor, socialization and gender ideology contentions have garnered the most support. The sex typing of chores among children has been consistently demonstrated, as well as the consistency of gender role attitudes concerning domestic roles across generations within families. Clearly, the patterns of the division of household labor represent one of the more static dimensions of marital and family relationships.

DIVORCE, CHILDREN AND

Unlike the majority of adults who enter divorce more or less voluntarily, for children, parental divorce is imposed upon them. Some children, particularly older ones, may have seen it coming, whereas others are completely unprepared and do not know what to expect or how to act. Initial reactions often include feelings of shock, anger, confusion, disappointment, and even distress. How long do these feelings last and how common is it for children to suffer more serious adjustment problems, such as getting seriously depressed, blaming and doubting themselves, performing poorly in school, or acting out (lying, cheating, stealing, alcohol and drug use)? How much do children differ in how they adjust to divorce, and which factors are associated with these differences?

This entry explores how children adjust to their parents’ divorce. First, it examines several outcomes that children and adolescents in divorcing families commonly perform worse on than their peers in nondivorced families, including academic achievement, self-concept, social competence, and intimate relationships. Then it reviews evidence on psychological and interpersonal adjustment among young adults whose parents have divorced, including

a discussion of the increased risk of their marriages ending in divorce. Throughout the discussion, this entry describes possible reasons why parental divorce is linked with child maladjustment and factors that may explain why children of divorce are disadvantaged. In the concluding section, this entry examines areas of personal growth and maturation.

Dimensions of Child Adjustment

There is abundant evidence that on average children who have experienced parental divorce fare worse on several indicators of social, emotional, and behavioral adjustment than their counterparts in families with continuously married parents. Methodologically rigorous studies as well as authoritative reviews of the literature consistently indicate adverse effects of parental divorce on child, adolescent, and young adult adjustment. In other words, the average adjustment level for children of divorce is somewhat lower than the average level for children who have not experienced parental divorce. Yet there are wide differences in adjustment within both groups of children, and many factors are related to these differences. This entry recognizes the general pattern whereby child adjustment is disturbed following parental divorce, but it concentrates on describing why some children of divorce fare better and others fare worse. Thus, the objective is to describe the nature of these differences in children’s short-term and long-term postdivorce adjustment and factors that help researchers understand why some children adjust more effectively than others.

Children’s Initial Reactions

Differences in children’s reactions to parental divorce are evident as soon as they are notified of the news. Interviews with parents of children ages 6 through 12 have found that approximately half of the children responded to news of the separation with distress or sadness, fewer than 1 in 10 (9 percent) were angry, a similar proportion (8 percent) were relieved, and the remainder either asked questions or had no visible reactions. When children themselves were asked to describe their feelings upon hearing that their parents were

separating, they described a wide range of emotional responses. Reflecting a sense of loss, the most common reaction (reported by half of the children) was sadness. Other emotions children reported feeling in abundance included being confused (22 percent), scared (22 percent), surprised (15 percent), angry (13 percent), and glad (11 percent). By 1 year postseparation, children were feeling better and stronger and less sad and guilty, but a small percentage (9 percent) continued to feel angry. It should be noted that although the prevailing initial reactions were negative in tone a substantial minority of children were described as being relieved or described themselves as glad. For many children, parental divorce signals a transition in family relationships whereby daily tensions, bickering, and hostility between parents subside, creating hope for a happier family environment.

Academic Achievement

On average, children of divorce do more poorly than their peers on various measures of academic performance, including grade point averages, standardized test scores, and educational attainment. For example, children whose parents divorced are more likely to drop out of high school than their peers with continuously married parents. Research shows that differences across family types tend to be small, however, and these differences often disappear when other relevant variables are taken into consideration. For example, studies have documented that many children who are not doing well academically following divorce were not doing well prior to marital dissolution. Other studies have found that deficits in academic performance among adolescents whose parents divorced were as much due to lower levels of family, social, and financial resources as the divorce itself.

Looking exclusively at children who have experienced parental divorce, there are wide differences in children's achievement on reading tests. Nearly three in five boys (59 percent) and nearly half of girls (47 percent) scored within the average range on a reading comprehension test 1 year after marital disruption. At the same time, roughly one fourth of boys (23 percent) and girls (24 percent) whose parents divorced scored below average, while a significant minority (19 percent of boys and 29 percent of girls) scored significantly above

average. Changes in reading achievement were assessed by comparing children's rankings at a baseline measurement prior to family disruption and then a follow-up 1 year postdisruption. Researchers found that there was no change in the year of the study for half the sample (50 percent of boys and 57 percent of girls), whereas scores declined for roughly one in three boys (29 percent) and girls (32 percent) and improved for a smaller group of children (21 percent of boys and 11 percent of girls). In sum, there is considerable variation in how children's academic performance is affected by parental divorce, with approximately one in three children performing worse in the year following divorce and a slightly smaller proportion improving academically.

Conduct Problems

A widely studied topic in divorce research is the consequences of marital dissolution on children's conduct problems. One reason this research question receives so much scholarly attention is that conduct problems appear to be the aspect of children's functioning most seriously influenced by divorce. Although children of divorce on average score only marginally worse than other children on measures of social and psychological adjustment, they suffer more pronounced behavioral problems.

Studies consistently report that on average children whose parents have divorced experience more behavior problems (e.g., aggression, disruptive behavior), engage in more delinquent activities, and exhibit higher rates of alcohol and drug use than their peers living with continuously married parents in either happy or distressed marriages. Specifically, boys and girls with divorced parents were more likely to shoplift, purposely damage property, run away from home, be drunk in a public place, be picked up by the police, or have gone to court. In addition, research has found that across a variety of community contexts drug use is more prevalent among adolescents living in single mother, single father, and stepparent households than among their peers living in households headed by two biological parents. Results such as these suggest that the effects of divorce on children's conduct problems are robust, but there is also evidence indicating that family processes (such as parenting behaviors) associated with divorce also

exert important influences on adolescent behavior. For example, child behavior problems are directly associated with parents' use of negative control (i.e., disapproval, criticism, and hostile threats). Further, the behaviors of both residential and non-residential parents are important. Research has observed fewer conduct problems among adolescents with a highly involved nonresidential father compared to those with a relatively uninvolved nonresidential father.

Notwithstanding the importance of the consistent finding that children whose parents have divorced are more likely to engage in problem behaviors, there are many notable differences among children in this domain. Researchers have tracked changes in children's behavior problems during the year immediately following the ending of their parents' marriage and demonstrated that on average parental divorce had no significant effects on girls' behavior and modest effects on boys' behavior. It is important to note, however, that there was substantial variation in how children responded to parental divorce, with behavior problems increasing for some and declining for others. Part of this variation is associated with gender. For example, following divorce, nearly half of boys (49 percent) and girls (43 percent) scored within the average range on the Behavior Problems Index. However, a large minority of boys (42 percent) and nearly one third of girls (31 percent) exhibited more problems than average, and behavior problems were below average for roughly one in ten boys (9 percent) and one in four girls (26 percent). In sum, similar to the pattern reported earlier for children's academic achievement, the occurrence of behavior problems did not change for nearly half of children in the year following parental divorce, but such problems increased for more than one third of children and decreased for a smaller proportion. Taking into account children's predivorce behavior problems, nearly half (48 percent) of boys and girls exhibited no change over the 2-year period spanning from before the divorce to 1 year following the divorce. Over the same period, scores worsened for one third of the sample (35 percent of boys and 33 percent of girls) and scores improved for nearly one in five boys (18 percent) and girls (19 percent).

Similarly, studies have reported an overall pattern that children of divorce are somewhat more

likely than their peers to use drugs, but there is considerable variation in drug use among adolescents living in different family types, with higher use among boys, Whites, adolescents who moved more often, those who dropped out of school, and those reporting lower quality attachments to their parents. There are also large differences in how often children use drugs depending on the type of family they live in following divorce. Compared to drug use among adolescents living with both biological parents, drug use was approximately 13 percent higher in mother-only and mother-stepfather households and 23 percent higher in father-only households, and 25 percent higher in father-stepmother households. Once again, findings such as these suggest that family processes (in this case, with whom the child lives) have an important influence on children's development in addition to the effects stemming from the divorce by itself.

Intimate Relationships and Adolescent Sexual Behavior

Research consistently supports an association between parental divorce and both early sexual activity and the risk of adolescent childbearing. Studies have reported that boys and girls in divorced, single-parent families and stepfamilies began sexual activity at earlier ages and had higher rates of sexual activity than did their peers with two continuously married, biological parents. For example, research estimates that boys' median age when they have their first sexual experience was 17.3 in families with two biological parents, compared to 16 in single-parent families and 15 in stepfamilies. Unfortunately, few strong studies with large, representative samples have followed families through the divorce process to examine changes in interpersonal relationships and adolescent sexual behavior.

The behaviors and attitudes of residential parents (typically mothers) and nonresidential parents (typically fathers) largely account for the increased likelihood of early sex among children of divorce. For example, compared to parents in other family types, divorced parents are more likely to have permissive sexual attitudes and are less likely to closely monitor their children's activities. Divorced parents' greater acceptance of adolescent sexual

activity, their greater tendency to engage in (and thus model) nonmarital sexual relationships, and their more sporadic supervision of their teenage children increase the risk of teen sexual activity. For example, divorced parents are less likely to discourage their children's relationships with peers who may be sexually active.

Consequences of Parental Divorce for Young Adults

Research on women ages 19 to 35 indicates that parental divorce exerts relatively small effects on young women's heterosexual relationships. Although the differences are not robust, compared to their peers whose parents were continuously married, young women with divorced parents reported less trust in their partners, less relationship satisfaction, more love for their partners, and more ambivalence, conflict, and negativity. Parental divorce appeared to influence young men differently, with effects depending on whether their partners' parents were also divorced. For example, in marriages in which both partners experienced parental divorce, men reported less trust in their partners' honesty and benevolence. But in marriages in which just the man experienced parental divorce, men reported greater trust in their partner's benevolence. These findings are consistent with a large body of research and theory suggesting that compared to men women are socialized to value intimate relationships to a greater extent and invest more heavily in them. When parental divorce occurs, women may respond with more realistic views and more caution in their own relationships. Among young women whose parents divorced, reports of friendship-based love in their romantic relationships vary considerably. For some women, the pain and disappointment associated with parental divorce elicits a fear of intimacy and mistrust in romantic partners, whereas other women respond with a more positive, adaptive, and realistic understanding of the difficulties of intimate relationships.

Intergenerational Transmission of Divorce

Even though research suggests that divorce has relatively small effects on young adults' romantic

relationships, adults whose parents have divorced have a slightly higher likelihood of divorce than do adults whose parents never divorced. The reasons for this intergenerational transmission of divorce effect are not entirely clear but could be due to young adults of divorce being more willing to end unhappy relationships because they have witnessed their parents do so, children of divorce possessing more favorable attitudes toward divorce, inheriting certain undesirable personality characteristics from their parents (e.g., neuroticism, narcissism, depression-proneness), and observing and learning unhealthy relationship interactions. Most likely, the intergenerational transmission of divorce effect is caused by some combination of genetically-based personality dispositions and modeling effects.

Personal Growth and Maturation Following Divorce

Although there are a number of negative effects of divorce, there also appear to be a number of positive outcomes that may follow divorce. With respect to the negative effects of divorce noted earlier in this entry, there is evidence that these effects are short-lived and that most children and young adults return to their predivorce level of functioning within 2 to 3 years following the divorce. Rigorous studies following families through the divorce process demonstrate that both children and parents have the most difficulties during the period when parents separate physically and for the next 1 to 2 years. For example, an analysis of a national sample of adolescents tracked changes in their well-being from 3 years prior to divorce to 3 years following divorce. The researchers found that among adolescents whose parents divorced, objective indicators of academic performance (e.g., test scores in science, reading, and social studies) exhibited a continuous and linear decline. However, self-report measures of educational aspirations, self-esteem, and locus of control were characterized by a U-shaped pattern, whereby the lowest levels occurred during the divorce, after which levels rebounded to predivorce levels. Perhaps divorce initiates a downward behavioral spiral in academic achievement that is difficult to reverse, whereas divorce has only a short-term effect on personality and cognitive variables.

In addition, research suggests that approximately 10 percent of children with continuously married parents exhibit serious behavior problems, compared to 20 to 25 percent of children with divorced parents. Although this may seem to be a large difference, note that the vast majority of children in both groups are considered to be well-adjusted. Such findings support the idea that children are resilient in that they bounce back relatively quickly from an upsetting event, such as divorce. Support for the idea that children are resilient to the effects of divorce also comes from the children themselves. John Harvey and Mark Fine gathered accounts of the divorce experience from thousands of college students whose parents divorced earlier in their lives. A consistent theme in their stories about their experiences was that they managed to cope well in the face of upsetting circumstances and that their adjustment improved over time.

There is also evidence that divorce may have some positive, growth-inducing effects. Research has suggested that the experience of divorce may help children mature more quickly and that they learn some life management skills more quickly than they would had their parents remained married. Young adults, for example, may have more realistic expectations about romantic relationships, may have an enhanced ability to empathize with their parents and others experiencing difficult circumstances, and may have clearer and more carefully thought-out life goals than those whose parents did not divorce. Thus, divorce is not a uniformly negative experience. Negative effects tend to diminish over time, and there are some often overlooked positive or maturational effects as well.

Divorce as a Process

Researchers initially studied divorce as if it were a single event that required adaptation, similarly to how individuals adjust to such single events as natural disasters or traumas. However, long-term studies have clarified that divorce is more accurately thought of as a process rather than as a single event. It is a process in several ways: It not only requires long-term adjustment but also there are a number of predivorce (e.g., high levels of parental conflict, disrupted parenting) and postdivorce experiences (e.g., legal conflicts between the

ex-spouses, parental disputes regarding childrearing and the amount of time that each will spend with their children) that separately and together contribute to how well children and young adults adapt to their changing circumstances. Perhaps the most important implication of this focus on process is the notion that one must consider where an individual is situated on the journey through the divorce process when trying to understand that person's experience with and adjustment to divorce.

Another implication of this focus on process is the notion that there are important differences in how children and young adults adjust to divorce. Not only are all individuals unique in some ways in terms of how they cope with stressful circumstances, but also individuals vary in terms of such societal and cultural dimensions as race/ethnicity, gender, socioeconomic status, sexual orientation, and the type of family in which they live. To understand an individual's adjustment to divorce, it is important to take into account not only where in the process the person is but also where he or she is situated in terms of these societal dimensions.

For example, there is some evidence to suggest that divorce has fewer and less severe effects on African-American children than it has on European-American children. In terms of the child's gender, there was initially some speculation that boys were more negatively affected by divorce than were girls. However, more recent research has suggested that there are few clear-cut gender differences in reactions to divorce and that predivorce differences between boys and girls affect their adjustment to divorce.

Although the popular culture and mass media perpetuate images of parental divorce as a devastating experience, research suggests that for most children, adolescents, and young adults, adjustment to parental divorce is a process that typically lasts for a couple of years, after which most individuals respond successfully. The experience of parental divorce tends to be stressful and painful during the period leading up to and immediately following parental separation, but the experience is best viewed as a process that involves family reconfiguration, resilience, maturation, and personal growth.

DIVORCE, EFFECTS ON ADULTS

Divorce is the legal dissolution of a marriage. Divorce is a complicated and painful experience that includes an emotional, financial, and social dissolution of a couple. Divorce is listed among the most stressful events an individual can ever encounter. However, the effects of divorce are not the same for all adults. For some it is a stressful negative crisis, and for others it can be a welcome relief. But for most there is probably a combination of both positive and negative effects. The effects of divorce to be discussed in this entry include changes to the psychological (e.g., life satisfaction, happiness, divorce adjustment), physical (e.g., acute and chronic disease, mortality), and financial well-being (job loss, financial stability) of former spouses. Divorce adjustment is measured in a variety of ways, which include how

happy one is with the divorce, whether the individual perceives the divorce as a good or bad idea, and how attached the individual is to the former partner. The effects of a divorce on adults can vary based on several factors, including individual characteristics, the quality of the marriage predivorce, and the presence of children. This entry will review the positive and negative effects of divorce on adults as influenced by various individual and situational factors as well as by the differences of gender.

Negative Effects of Divorce

Divorce is a stressful significant life event that represents loss and transition. One loses a valued relationship and the emotional and material resources provided by that relationship. This loss requires numerous adjustments as one transitions from a married to a single lifestyle. As with any change, an individual may encounter feelings of anxiety, insecurity, and doubt. Divorce also requires individuals to manage responsibilities (household tasks, childcare duties, financial matters, etc.) that one's spouse may have previously handled. These additional duties can serve as daily hassles that can be further sources of stress. In general, the accumulation of stress associated with divorce can have a negative impact on the well-being of those affected.

Accordingly, scientists have found that the well-being of divorced adults is substantially lower than that of married adults. When compared to married adults, divorced adults have lower rates of life satisfaction and happiness; higher rates of depression, anxiety, and acute and chronic disease; higher likelihood of alcohol abuse, suicide, and death; more social isolation; and lower economic stability and wealth. Divorced adults also have higher rates of institutionalization in correctional facilities, mental institutions, hospitals, and convalescent homes than married adults. The negative effects of a divorce subside after a few years for some, but for others they persist indefinitely. The emotional support provided by repartnering or remarrying is largely credited for resolving the negative effects of divorce for most adults.

Divorce negatively affects the financial stability and wealth of most individuals. However, compared

to men, women are more likely to be affected due to the higher likelihood of maintaining custody of the children, the low levels of child support most receive, and the gender disparities in salaries and employment opportunities. Furthermore, married women are more likely to be unemployed and responsible for childcare and household duties, which negatively impact their professional development and earning potential when they return to the workforce postdivorce. Men fare better after a divorce than women do because their new households are generally smaller and because they do not contribute the same proportion of their income to their former households after the divorce as they did prior. In addition, being married and having children does not negatively affect their career advancement. In general, men do not equally share in the domestic chores; therefore, they are more likely to remain continuously employed and thereby able to consistently sharpen their professional skills and protect their earning potential.

Positive Effects of Divorce

Most studies that examine the effects of divorce on adults primarily focus on negative outcomes; however, there are some positive consequences following divorce. For many, divorce is often interpreted as a second chance at life. For example, research shows that divorced adults report higher rates of autonomy, personal growth, self-awareness, and occupational success than married adults. These benefits may be related to their increased sense of freedom and independence. However, these advantages are more likely when there are adequate levels of financial and social support from friends, family, or new partners. Employment also provides divorced adults with financial support and alleviates the stress of reentering the workforce. In fact, individuals who are employed at the time of their divorce report less divorce related stress than those who are not employed. Moreover, divorced individuals with new partners show greater positive adjustment and life satisfaction than those who have not developed new romantic relationships. A new partner positively affects well-being because it lessens the anxiety, depression, and social isolation experienced after the loss of a companion.

There also is assistance with household tasks and expenses.

Individual and Situational Differences

The adjustment to and distress experienced after a divorce may depend on a variety of factors. One such factor is an individual's perception of the meaning of marriage. Individuals who perceive marriage as a lifetime commitment experience higher levels of depression after divorce than those who view marriage as just another relationship that comes and goes. In addition, individuals who endorse several dysfunctional attitudes about divorce (e.g., getting divorced means the people are damaged goods or divorce will permanently damage the children) report higher levels of postdivorce distress than those who endorse a few of these attitudes.

A person's perception of the cause of the divorce also can affect adjustment to divorce. Individuals who blame themselves or external factors, such as work or family interference, for their divorce have poorer adjustment than those who attribute the divorce to incompatibility (partners too dissimilar or too young for marriage) or to their spouses (spouse cheated). Paul Amato and Denise Previti suggest that people who believe the divorce was avoidable because of the choices they made have more difficulty recovering from the divorce and letting go of their former spouse than those who believe the relationship itself or their spouse was flawed.

The distress experienced postdivorce also may vary depending on whether or not the individual initiated the divorce and/or wanted the divorce more than his or her former spouse. Although studies suggest that both initiators and noninitiators are likely to experience distress, there are differences in the timing of the distress. Cheryl Buehler asserts that the initiator is more likely to have started the grief process before the legal separation is final, whereas the noninitiator is not likely to begin the grieving process until the legal process becomes a reality. Overall, however, the initiator reports more positive divorce adjustment than the noninitiator. Similarly, the spouse who wanted the divorce most reports higher levels of divorce adjustment and life satisfaction. Scientists

believe initiating the divorce may aid in divorce adjustment because one is taking an active role in finding a solution to a problem, and this decision gives the individual the perception of control over one's life.

The age at divorce and duration of marriage also are associated with divorce adjustment. Older individuals and those who have been married longer have a more difficult time adjusting to divorce. Amato and colleagues explain that this difference in adjustment could be due to greater marital investments made into the marriage (children, emotional effort, and financial support) and the perception of fewer dating opportunities once divorced. It could also be that older adults have less favorable perceptions of divorce.

The quality of the marriage prior to the initiation of a divorce is another factor related to divorce adjustment. Some argue that divorce serves as an escape from a poor marriage. In support of this perspective, research has found that individuals from highly distressed marriages report greater levels of happiness following divorce than those from low-distress marriages. In addition, adults dissolving unsatisfactory or unfair marriages are less depressed than those dissolving satisfying and fair marriages. (Divorces in these cases were probably not mutually desired.) However, relief does not come for all who leave unsatisfactory marriages. Adults who leave marriages high in conflict (e.g., verbal or physical aggression) do not immediately experience relief. Instead, these adults face a greater likelihood of depression following divorce because divorce may trigger more conflict from abusive spouses.

Gender Differences

Research shows that divorce is more detrimental to the psychological well-being of women than to men. Specifically, women have been found to experience higher rates of depression and lower levels of happiness following divorce than men. The likelihood of depression and a decline in happiness is even greater if women have preschool-aged children at the time of the divorce. In addition, women who have small children are more likely to abuse alcohol post-divorce than women who do not have small

children or older children. The gender differences in psychological well-being following divorce have been partly attributed to the differential economic changes that accompany divorce. It has been consistently found that women suffer more financially after divorce and are more likely to maintain custody of the children. For example, women who experience divorce with young children will likely require full-time childcare. These childcare costs can drastically affect her household budget. In addition, as the custodial parent, she must deal with the difficulties of misbehavior and illness, which can be a financial strain and can affect her own psychological and physical well-being.

Nonetheless, the picture is not completely bleak for divorced women. Studies show that since women are more likely to be the initiators of divorce, they also are more likely to recover successfully from the divorce. In addition, women are more likely than men to be satisfied with the legal settlements associated with divorce in terms of custody, visitation, and asset allocation. Being the initiator of her divorce and thereby taking an active role in changing her life, receiving a favorable legal settlement, and having a higher likelihood of seeking support from family and friends all allow women to effectively adjust to the challenges a divorce brings.

Although men are not as likely as women to openly express the hurt and pain they are experiencing, divorce is not easy for them. Research shows that men have an increase in alcohol abuse following divorce. In addition, men who are fathers of preschool-aged children have higher rates of depression postdivorce. This depression may be due to the loss of daily contact with their children or to the diminished parental control they have over their children's lives. Divorced fathers are significantly less likely than divorced mothers to maintain custody of their children, and many fathers have strong concerns about the courts' favoritism toward mothers in determining custody and visitation arrangements.

There also are differences in the psychological well-being between divorced adults with children (particularly preschool-aged children) and those divorced adults with no children or adult children. These differences can be partly explained by the continued contact with the former spouse

due to parenting obligations. Continued contact may exacerbate the conflict and feelings of anger and hostility between former spouses. The conflict may include legal, verbal, and physical disputes. Divorced individuals with no children or adult children do not have to maintain a relationship with their former spouses and can more effectively escape the conflicted relationship.

In the future, researchers should examine the dynamics of nonmarital relationship breakups now that fewer adults are marrying and are cohabitating with their partners instead. It will also be important to understand the characteristics of successfully remarried divorced adults in order to help the divorced prepare for their next marriage since the second marriage is at a higher risk of divorce than the first.

DIVORCE, PREVALENCE AND TRENDS

All marriages end in either divorce (many researchers also include separation as a means to end a marriage and thus equate it to divorce) or death. Historically, death has been the predominant means by which marriages have ended. Over the past century, however, declines in mortality and increases in divorce have altered the predominance of death as the ending state of marriage. This entry focuses on prevalence and trends in divorce in the United States. For women born just before the turn of the 20th century, about 17 percent could expect to see their marriages end in divorce, with the remainder 83 percent seeing their marriages end in death. For women born around the middle of the 20th century, divorce had increased to claim 42 percent of marriages. It is more difficult to make predictions for women born after the middle of the 20th century because they are still at the ages where both death and divorce can occur. A best estimate, however, is that about 44 percent of recently contracted marriages will end in divorce. This figure is among the highest in the world. For example, in France, Germany, the Netherlands, and Hungary about 38 percent of marriages are expected to end in divorce. The figure is 25 percent in Switzerland, 15 percent in Israel, 6 percent in Turkey, and 1 percent in India.

Interestingly, for women born in the first quarter of the 20th century, declines in mortality more than compensated for increases in marital dissolution so that women spent a growing percentage of their lives married. Since that time, however, increases in divorce (in conjunction with substantial increases in age at marriage) have reduced the percentage of life a woman spends married. Recent data indicate that women can expect to spend only about 41 percent of their lives married.

For the most part, divorce rates (measured as divorces per 1,000 married women age 15 and over in a given year) in the United States have risen steadily since the end of the Civil War. Less than 2 marriages per 1,000 ended in divorce in 1870 compared to about 18 marriages per 1,000 in 2000. The risk of divorce has not increased monotonically over time, however. For example, divorce was

higher than expected following World War I, much lower than expected during the Great Depression, and much higher than expected immediately following World War II. The 1950s and early 1960s once again saw lower than expected rates of divorce, followed by a dramatic increase in divorce rates starting in 1965 that led to higher than expected rates during the 1970s and early 1980s. Since about 1980, however, rates of divorce have stabilized and have even declined somewhat. Indeed, the stability and decline in divorce rates evidenced since 1980 indicate an unusually long plateau in the long-term historical rise in divorce rates. At no point in the last 150 years have divorce rates failed to increase for such a lengthy period of time.

Instead of asking what fraction of marriages end in divorce in a given year (with divorces in a year being composed of marriages that were formed over a large number of years in the past), researchers can ask what fraction of marriages contracted in a given year will eventually end in divorce (with these divorces spread out over a large number of years in the future)—that is, moving from period divorce rates to cohort divorce rates. Looking at the proportion of marriages formed in a given year that eventually end in divorce, there is a similar long-term upward trend in divorce, followed by a plateau beginning about 1980. Note, however, that deviations from the long-term upward trend using this second measure are much less substantial because divorces are cumulated across the lifetime of a marriage cohort. That is, for a given marriage cohort, the risk of divorce is averaged over a number of historical periods that may include periods of both below-average and above-average risk. For example, women married in the mid-1950s would have been exposed to the relatively low divorce rates of the late 1950s and early 1960s as well as to the substantially higher divorce rates of the 1970s and the subsequent stability and decline in divorce rates in the 1980s and onward.

Period Influences and Cohort Influences

These two ways of measuring divorce reflect the fact that there are two basic ways for explaining changes across time in the occurrence of divorce: period and cohort. Period influences refer to those

factors that affect the risk of divorce uniformly for all marriages at a given point in time irrespective of when those marriages were formed. For example, the negative economic circumstances associated with the Great Depression are assumed to have depressed the risk of divorce for all married couples during the 1930s, irrespective of when their marriages were formed. Cohort influences, on the other hand, focus on circumstances affecting divorce that are unique to a given marriage cohort, circumstances that reflect the unique configuration of historical circumstances impinging upon that marriage cohort. For example, marriages formed in the 1950s may have been uniquely impacted by the convergence of relatively prosperous economic conditions and small cohort size that rendered their marriages unusually stable over their lifetime.

Choosing between period and cohort explanations is a difficult task made even more complex by the necessary mathematical relationship that occurs between the two when combined with age (the so-called age-period-cohort conundrum; e.g., cohort is simply the difference between period and age). Yet not denying the possibility that cohort effects occur in conjunction with period effects, most analysts agree that period effects on divorce have dominated, at least over the span of time that reasonable data are available (the last 100–150 years in the United States). Period effects can and have been used to explain the long-run rise in divorce, as well as to explain the deviations from the long-term trend. For example, some of the sharpest shifts in divorce rates over the past century have been attributed to period forces such as the Great Depression, World War II, the rapidly evolving attitudes toward out-of-wedlock childbearing, women's labor force participation, no-fault divorce laws, reduced stigma attached to divorce, and non-marital cohabitation that occurred in the 1970s.

In their simplest form, period and cohort concepts are simple accounting mechanisms. That is, they can be used to describe patterns of change across time but without additional information do not by themselves elucidate reasons explaining the observed pattern. Although this procedure perfectly describes any temporal variation in divorce, it does little to explain why such variation has occurred. Deeper explanations require information about the nature of periods and cohorts—that is,

the behavioral mechanisms that lead periods (or cohorts) to vary from each other. These behavioral mechanisms are necessarily tied to the demand for marriage relative to available alternatives (e.g., cohabitation), which when altered disrupts the balance of marriage and relevant alternatives and leads to a change in the risk of dissolution (either upward or downward).

Normative and Structural Arguments

Most research focusing on changes in the demand for marriage can be characterized as emphasizing either structural or normative forces. Structural arguments most often focus on decline in the number of functions performed by families associated with the rise of extrafamilial institutions responsible for employment, education, health care, and so on. That is, the demand for marriage has tended to decline over time because the bundle of amenities formerly available only in a marriage is now available elsewhere. One of the most significant structural changes noted by previous researchers that has affected marriage is the movement of married women into the paid labor market, a trend that is argued to reduce the economic interdependence of spouses, thus increasing the risk of divorce.

Normative arguments, on the other hand, emphasize the growth of individualism over time, an increase in value placed on personal gratification and a decrease in a sense of family obligation. Normative arguments thus predict a lowered demand for marriage as various alternatives become more attractive. As a consequence of these cultural changes, societalwide norms regulating divorce have been replaced by norms allowing individual decisions based on rational choice—where rationality includes efforts to maximize individual happiness. This cultural shift has led to a reduction in legal barriers to divorce, as well as a proliferation of adult alternatives to marriage (e.g., cohabitation, living alone). The net result of these shifts in normative orientation is also a greater risk of divorce.

Of course, both structural and normative shifts are likely to have occurred simultaneously as components of larger processes of industrialization and modernization. Indeed, it is likely that structural

and normative changes have reinforced each other over time. For example, divorce in one generation becomes the engine of divorce in the next generation. As men and women adapt to the consequences of divorce, they set the stage for even greater weakening of the historical interdependence of spouses and openness to new alternatives for adult living. Divorce becomes an acceptable solution to domestic dissatisfaction, and withdrawal from the labor force that generates economic dependence becomes a risky venture that few men and women are willing to take. There is also evidence in support of an intergenerational transmission of divorce where children of divorce are more likely to divorce themselves. Thus, changes in marriage and divorce are multidimensional, and failure to recognize this fact will only lead to a more limited understanding of changes that have occurred, as well as the plausibility of future paths that change may take.

Increasing rates of divorce over time imply, therefore, a scenario wherein both the structural and normative foundations of marriage have weakened over time. Husbands and wives have become increasingly less interdependent economically and public stigma associated with divorce has waned. Accordingly, spouses are increasingly making choices about staying together that are not limited by economic necessity and that are made in a context of permissive attitudes toward divorce and a growing range of viable living alternatives outside of marriage. This is a somewhat crude theoretical position, but it does remind researchers to consider a broad range of alternatives when thinking about what drives differences in rates of divorce, both period and cohort.

Concluding Remarks

Finally, it is difficult to make firm statements about differentials in the risk of divorce that remain constant across time. Change in risk factors occurs because marriage is based on different foundations across different eras, and different eras offer different alternatives to marriage. That said, recent decades have witnessed the following differences (among others) in the likelihood that divorce will occur. Blacks are more likely to divorce than are Whites; marriages formed at young ages are more

likely to dissolve than marriages formed at older ages; marriages preceded by a spell of cohabitation are more likely to end than marriages not preceded by cohabitation; marriages that involve a premarital birth are more likely to end in divorce; marriages in which at least one of the partners was married before are more likely to dissolve; marriages involving spouses with less education are more likely to end; and marriages that involve spouses with heterogamous traits (e.g., wide differences in education, age, race) are more likely to dissolve. Finally, there appears to be an intergenerational transmission of divorce. That is, marriages in which at least one of the spouses has divorced parents are more likely to end in divorce.

DIVORCE AND PREVENTIVE INTERVENTIONS FOR CHILDREN AND PARENTS

Every year in the United States, more than a million children experience their parents' divorce, and nearly half of all children will spend some portion of their lives in a single-parent family.

There is substantial variation in the course of children's long-term adjustment. However, most children experience considerable distress in the early stages of a breakup. Variation in children's long-term outcomes depends largely on how their parents handle the end of their marriage and the quality of family life they create for their children over time. The impact of divorce on children is shaped by a number of risk and protective factors including individual child characteristics, parenting and family factors, and the quality of support available to children and families. Research on these mediating factors is valuable because this knowledge base can be translated into essential ingredients for effective policies, best practice standards, and evidence-based interventions for children and families. This entry describes preventive interventions that incorporate protective factors known to relate to more positive outcomes for children and their parents.

Risks Associated With Divorce and Children's Adjustment

Numerous studies underscore the role of divorce and family conflict as a major stressor for separating parents and their children. A meta-analysis of 95 studies involving over 13,000 children showed that divorce poses specific risks for children socially, emotionally, and academically. Children whose parents divorced had more than double the rate of difficulties requiring mental health services compared to children from never divorced families. Problems may endure into adulthood for a significant minority of children, including a heightened risk of social and emotional difficulties, socioeconomic problems, poorer subjective well-being, and a greater likelihood of divorce in their own marriage. These sobering outcomes warrant concern and intervention, but they are not inevitable, nor are they applicable to all children who experience divorce. Preventive interventions designed to help children cope with family changes have been shown to enhance children's adjustment to this major life change.

Preventive Interventions for Children

Coping with unwanted, uncontrollable, and often unexpected life-altering experiences can be

enormously challenging, if not overwhelming, for most children. As they watch their parents grapple with painful emotions, children often keep their own distress to themselves—often furthering their isolation. Programs such as the Children of Divorce Intervention Program (CODIP), created by JoAnne Pedro-Carroll and her colleagues, provide shared group support and coping skills and have been shown to reduce the stress of a breakup on children and to foster their resilience and adaptive coping.

Protective factors such as effective coping skills are like shock absorbers that help children manage strong emotions and deal with myriad family changes. Providing children with age-appropriate information and clarifying misconceptions about divorce are approaches that are related to better outcomes for children. Children who blame themselves and who have harmful misconceptions about the divorce have been shown to have more adjustment difficulties. The CODIP focuses on supporting children emotionally by providing a safe setting where they can share their feelings, strengthen effective coping skills, clarify misconceptions, and learn to disengage from problems that are beyond their control. Several studies show that program children were rated by their teachers and parents as having improved in their adjustment at home and at school more than control groups of children who did not participate in the program. Children in the program reported feeling less anxious and more confident about their ability to deal with problems and life changes than nonprogram children. The positive benefits of this preventive intervention even extended to children's health. Two years after participating in the program, children had fewer visits to school health offices with complaints of headaches, stomach aches, and general malaise than children in a nonprogram control group.

What are the active ingredients that contribute to the effectiveness of children's programs such as CODIP? Studies show that active coping that involves problem solving, communication skills, and positive thinking are related to less depression and help to mitigate the effects of stress on children. Children's evaluations of the success of their coping efforts in the face of stressful situations appear to be linked to their active coping and reduced anxiety. In other words, children can be empowered

with skills for helping them express and manage their emotions and cope effectively with difficult times. Divorce poses enormous challenges that children are often expected to take in stride. Apparently, learning skills and strategies for dealing with family changes gives children a sense of competence and confidence that there are *some* aspects of their family circumstances over which they do have control. As one 10-year-old participant said of his experience in CODIP, "This group has been a safe place where I could talk about anything . . . it's helped me to see that divorce is sad, but it's not the end of the world for me or my family."

Preventive Interventions and Educational Programs for Parents

How children fare after a divorce depends heavily on how their parents go about ending their marriage and on the quality of life they create for their children. Specific family factors have been identified that have a profound, positive impact on children's lives over time. Most effective programs for parents are based on these protective factors. One such parent education program is ACT-For the Children (Assisting Children through Transition) in New York, which provides information and skills in a 7-hour, two session class for separating parents. Effective approaches that parents can use to nurture their children's resilience and healthy adjustment are based on the factors summarized below.

Encapsulated Parent Conflict

Ongoing conflict between parents is consistently linked to children's psychological problems. Especially toxic is conflict that is verbally or physically hostile, unresolved, and child focused. Nonaggressive conflicts that are resolved tend not to distress children any more so than nonconflictual discussions. Interestingly, if children are told that a conflict has been resolved, the negative impact on them is reduced. In contrast, unresolved and ongoing conflict sensitizes children to further acrimony, disrupts parenting, and is linked to behavior problems.

The implications of this research for educational and preventive interventions for parents are clear: Contain, resolve, or encapsulate conflict, and do not allow it to seep into every aspect of life and

erode precious relationships and one-on-one time with children. Parent education programs such as ACT-For the Children encourage parents to use skills for effective communication, conflict resolution, anger management, and to renegotiate their marital relationship as former spouses and lovers to a coparenting relationship with a vested interest in the important business of raising their children. The analogy of a business relationship implies a more formal, collegial, and less emotional way of relating to contain anger and defuse inflammatory verbal exchanges and interactions. Above all, the goal is to protect children from the harmful effects of ongoing conflict between parents.

Legal policies are needed that reduce acrimonious proceedings that exact a heavy toll on all family members—especially the children. Mediation and Collaborative Law are increasingly popular effective alternatives to adversarial approaches that can intensify parent conflict and negatively affect children. Significant positive outcomes were found in one 12-year follow-up study comparing divorce mediation to litigation. Just 5 hours of mediation resulted in greater satisfaction with the process, increased contact between nonresidential parents and their children, and reduced court hearings. Such proactive approaches hold much potential for reducing the negative consequences of divorce on children and families.

Parental Functioning and Psychological Well-Being

Another reliable predictor of children's healthy adjustment is the health and well-being of their parents. Divorce is an undeniably stressful process that can leave adults vulnerable to psychological and physical problems. Marital disruption has been shown to be related to suppressed immune system function, which may increase divorced adults' susceptibility to disease, chronic and acute medical conditions, and even death.

At a time when children are grappling with stressful family changes, they often encounter parents who are unable to provide the emotional stability and support that their children so urgently need. For children who are feeling vulnerable and worried about their future, having a well-functioning parent provides a protective pathway to healthy adjustment. Effective preventive interventions such

as ACT-For the Children emphasize to parents the importance of taking care of themselves physically and emotionally so that they can care for their children. Providing parents with information about healthy management of stress, warning signs that professional help may be needed, and links to additional supportive resources once a program has ended are effective approaches. Many programs provide such information and skills training. Although most parent education programs are of short duration, one consistent benefit appears to be that parents' awareness and use of supportive resources is increased. These programs should not be viewed as an end point for parents but as a means to the end of seeking additional support as needed to maintain healthy family functioning. Help seeking should be seen as a sign of strength, not weakness. This message has important implications for shaping legal policy to ensure that adults are not penalized in court proceedings because of having sought mental health care.

Solid, Supportive Parent–Child Relationships and Effective Parenting

Research on children's resilience in adverse circumstances has recurring themes in common with research on children and divorce: the importance of a supportive relationship between children and at least one parent or caregiver.

Studies consistently show that a healthy attachment relationship between a child and at least one parent or caregiver is a critical foundation for children's competence and resilience. Unfortunately, parent–child relationships can erode significantly after divorce, especially in high-conflict situations. Equally noteworthy is the fact that a solid, healthy relationship with one parent has the potential to buffer children from a negative relationship with the other parent. High-quality relationships serve as a lifeline that protects children from divorce-related stress, enhances their feelings of security, reduces fears, and conveys a message that help is available if needed.

A preventive intervention program called New Beginnings at Arizona State University is a program that includes dual components for residential mothers and their children. This intervention focuses on parenting skills, especially effective

limit setting and strengthening parent–child relationships through positive interactions and one-to-one time spent in pleasant activities. Short-term results of the program included reduced behavior problems in children. Impressive results were found in a follow-up study 6 years later. Adolescents whose mothers participated in the program had reduced symptoms of emotional difficulties, fewer acting-out behaviors, lesser use of marijuana and alcohol, fewer mental health problems, and fewer sexual partners.

Studies such as these underscore the central role of parent–child relationships and the protective process that can occur under conditions of emotionally secure connections between parents and children. Parenting skills that include warmth, nurturance, involvement in one-on-one time with children, and authoritative parenting with effective discipline contribute to high-quality relationships between separating parents and their children. Interventions targeted to separating parents that teach these effective parenting practices and strengthen parent–child relationships show much potential for reducing children’s stress and bolstering their resilience and healthy development.

Preventive interventions for children and parents highlight pathways toward reduced risk and in the optimal case, resilience. Separating parents and professionals working with them may want to consider the following practices:

- Provide a process and structure to resolve or contain conflict and reduce adversarial interactions.
- Educate parents about the power of collaboration and when safe to do so, working together on behalf of their children.
- Reduce economic decline for families—significant dollars are spent on protracted adversarial proceedings. Protect children’s right to financial support during their childhood and college years.
- Remind parents of the importance of healthy self-care and that seeking help when needed is a sign of strength.
- Protect children’s need to be kept out of the middle of parents’ conflicts.
- Encourage and affirm the importance of effective parenting and healthy relationships between the child and both parents.
- Give children age-appropriate information and prepare them for family changes.

- Reassure children in words and actions that they are loved and will always be well cared for—as children in support groups often say to their parents “even if you think we already know, tell us again.”

DOUBLE STANDARD IN RELATIONSHIPS

In its general form, a double standard is a set of rules, guidelines, restrictions, or a moral code that is applied more strongly to one group than another. Double standards typically emerge in areas characterized by stereotypes or different value systems, such as race, religion, or gender.

One type of double standard, which may be called an actor–observer double standard, can occur in romantic relationships. The name actor–observer comes from the actor–observer bias, which is the tendency for people to interpret other people’s negative actions based on their personality rather than on the situation, while basing their own actions on the situation rather than on their personality (e.g., “I act the way I do because of the situation I am in, while he acts the way he does because of the way he is”). A person in a relationship may consider his or her own actions to be normal, harmless, or nonthreatening, while considering those same actions by the other partner to be very troubling. Some examples include going out with friends of the opposite sex, forgetting to call on the phone, or being unresponsive. For instance, if a wife tells her husband she will call him at 8 o’clock but does not do it, he may attribute her behavior to something threatening, such as not wanting to call him, ignoring him, or cheating on him and may become quite upset. It may be the case that her cell phone battery died, she got a flat tire, or she simply forgot. If, however, the man fails to call his wife, he attributes his behavior to his situation (e.g., forgetting, flat tire), not to his personality.

This double standard may be especially common when one partner in the relationship has a preoccupied attachment style. A person with this type of attachment style is very concerned with closeness and is worried about being abandoned. Preoccupied people have chronic accessibility to thoughts about abandonment and closeness seeking, so many types of behavior, no matter how innocent, are often interpreted by them as a threat to the relationship. In summary, people may hold relational double standards so that what is appropriate behavior for them is not appropriate for their partner.

Perhaps the most common domain characterized by a double standard is that of sexual behavior. In Western society, it is widely believed that a sexual double standard (sometimes known as the double standard) exists so that more rigorous standards exist for sexually active women than men. Sometimes this is given the “studs versus sluts” designation; when a man is purported to have slept with many women, he is given nicknames such as stud or player, nicknames which are considered to be compliments. However, women who have purportedly slept with many men are often given derogatory nicknames such as slut or ho.

Although this type of double standard seems quite prominent to most people, much research suggests that a sexual double standard may not be as common today as it once was in the 1950s and ’60s, when some research indicated that women were perceived more negatively than men for engaging in high levels of sexual activity. Contemporary research by Michael Marks and his colleagues sheds some light on this disparity. One study shows that people in a social situation are likely to display a sexual double standard. This is because when people are in a social situation, they are more likely to act in a way they believe to be consistent with social norms. For instance, the researcher Solomon Asch found that people tended to do very well in a matching task when alone but when in the presence of others, tended to go along with the group, even when the group was wrong. Because many people believe the sexual norms surrounding the double standard to be true, they may act in accordance with them in order to appear consistent with social norms and avoid punishment (e.g., insults, teasing).

Another reason why a sexual double standard may seem prominent is the use of stereotypes in judging sexually active men and women. When a person is in a laboratory (which is generally a very quiet, socially isolated room) evaluating a sexually active person, it is very easy for that person to focus all of his or her mental resources to evaluating and thinking about that person. This makes it more likely that the target person is evaluated on things like personality than on how much sex that person has had. In true social situations, however, it is much harder to think about individual people because there is so much information to attend to. People have to pay attention to their own behaviors

and interpret signals from others. This means they have less mental energy to devote to person perception and therefore need to take mental shortcuts such as stereotyping. If this is the case, then the target person may be evaluated based on things such as how much sex that person has had (or is perceived to have had based on rumors, gossip, etc.) instead of their personal attributes.

Finally, it may be the case that people have a bias toward information that supports a sexual double standard. In other words, people remember more information that is consistent than inconsistent with stereotypes. Thus, it may be easier for people to notice and remember women being derogated and men being rewarded for sexual behavior than vice versa. Therefore, even if men and women are treated equally based on their sexual behavior, the instances that are noticed and remembered by people are the ones that are consistent with the double standard, giving rise to the appearance of its existence.

As a closing note, it is important to point out that holding or endorsing a double standard is not necessarily the same thing as hypocrisy. A double standard is holding different sets of rules for different people, whereas a hypocrite is someone who acts differently from what he or she says or believes. For example, if a person believes it is his or her right to have an extramarital affair but does not allow his or her spouse that right, the person holds a double standard. A person who claims extramarital affairs are immoral and wrong while maintaining one is a hypocrite.

DUAL-EARNER COUPLES

Dual-earner couples can be defined as those in which both partners are employed for pay while simultaneously maintaining a family life together. A significant subset of dual-earner couples are designated as dual career, defined as those in which both heads of households pursue high status occupations characterized by lifelong commitment and an opportunity structure that allows the expectation of advancement. The purpose of this entry is to give an overview of research on dual-earner couples, highlighting findings on both the strengths and challenges of this relationship type.

Research in this area began in the 1960s in England. Dual-career couples were viewed as a radical alternative to what was then perceived to be the most efficient and optimal division of family labor in which men were the primary financial providers and women the primary caretakers. This point of view largely ignored the fact that, prior to the Industrial Revolution, men and women had a long history of working collaboratively to maintain families. Indeed, it was not until the end of the 18th century and later that waged work was increasingly viewed as improper for women. This changed somewhat during World War II when women held factory and industrial jobs, but after the war, middle-class women were again encouraged to return home.

By the 1970s, influenced by economic and political factors, including the need for women's labor and the advent of feminism, increasing numbers of White middle-class women began to enter the paid workforce. Guided by the doctrine of separate spheres, few questioned that women would simply add the responsibilities of paid employment to those of the home, and most expected that paid employment would be experienced by women as harsher and more stressful than full-time homemaking. This gave rise to concerns of role overload (having to do too much) and role conflict, both work to family and family to work, so that fulfilling the demands of one role

(paid employment) would interfere with or preclude the ability to fulfill the demands of other roles (parenting and homemaking).

Contrary to expectation, however, studies found no negative effects of paid employment *per se* on women or on their children. In fact, there were often benefits. Despite increased demands on their time, research consistently showed that parents in dual-earner relationships spent no less time with their children than parents in relationships in which the mother was home full time, and their children scored just as well on measures of emotional and social development. Furthermore, children in dual-earner families often showed more egalitarian and less gender stereotypic attitudes as well as increased academic achievement, especially for girls. For women, across both race and class, the role of paid worker seemed to be a source of independent identity, increased self-esteem, purposefulness, enhanced social contacts, and inherent interest.

Findings also showed, however, that the extent of the benefits was influenced by a number of individual, occupational, and relational factors. On the individual level, women who had access to high-quality childcare and women who perceived paid employment as desirable were less depressed and less anxious than women without childcare and women who were employed but preferred to be home full time, respectively. On the relational level, women whose husbands supported their employment both behaviorally, by sharing the responsibilities of home and children, and attitudinally, by respecting the importance of their wives' work, were found to be less depressed than women whose husbands were unsupportive. On the occupational level, positions characterized by greater control, autonomy, challenge, and flexibility were associated with more positive outcomes than positions characterized by less control.

In 1975, as research in this area was just developing, approximately 45 percent of U.S. wives with children under 18 were employed. Only 15 years later, the percentage had risen to two thirds. Currently, dual-earner couples are the modal couple type in the United States with the result that approximately 78 percent of all employees are in dual-earner families.

More recent research has expanded the originally asymmetrical focus on women to include

men. Such studies find that work and home offer different emotional and cognitive benefits to both: home—relationships and time with family; work—stimulation and a chance to excel as well as significant financial benefits. In 2005, the median income of married couple families in which the wife was in the paid labor force was \$78,755 compared to \$44,457 for those in which the wife was unemployed. Although men, on average, continue to earn significantly more than women, wives' earnings contribute between 35 and 41 percent of family earnings, and some have estimated that as many as a third of dual-earner wives earn more than their husbands.

Wives' rising financial contributions led many to expect that family relations would become more egalitarian. Yet studies showed that increases in wives' financial contributions do not predict proportional increases in husbands' contributions at home. Wives' employment and wives' earnings take place in a cultural and relational context. In fact, studies in the United States and Israel and in industrialized countries in Europe and Asia showed that endorsement of key beliefs including the extent to which (1) masculinity is defined by the breadwinner role, (2) women work from choice rather than necessity, and (3) that infants need full time maternal care is a strong determinant of the availability of cultural and partner support for employed women. Among Western industrialized countries, Sweden has moved the furthest from these beliefs. As a result, dual earners, who now comprise close to 85 percent of Swedish couples, receive strong institutional supports including liberal paid parental leaves and extended childcare.

Over the last 3 decades, attitudes in the United States have changed dramatically. As a result, mothers who did on average one third more childcare than their husbands in the late 1970s do about one fourth more today. Responsibility for domestic work and the maintenance of relationships, however, remains considerably more asymmetrical, with women doing significantly more. Indeed, these asymmetries probably explain why professional women are more likely than professional men to be unmarried and childless and why studies find that husbands report more negative feelings about work than wives, while wives report greater negative feelings about home life than do husbands. Thus, one of the themes of current

research is identification of the kinds of programs, both corporate and cultural, such as work flexibility, supportive supervisors, paid parental leave, and quality childcare that will support work–life balance for both women and men, making dual-earner relationships less stressful and more beneficial for both the partners and their children.

DYADIC DATA ANALYSIS

Dyadic data analysis refers to a set of statistical techniques that model data from individuals who are connected or paired in some way. Dyads may be siblings, spouses, roommates, coworkers, neighbors, colleagues, or any other pairing that may be of interest to a researcher. Data analysis involving interconnected individuals violates the common simplifying assumption of statistical independence among units. As this entry describes, dyadic data analysis presents challenges for performing standard statistical tests, creating research designs, and constructing clear psychological hypotheses. Although complications do arise to make the statistical treatment more challenging, the payoff from dealing with these challenges is a richer understanding of social life from the most basic of human couplings—the dyad. This entry discusses several statistical issues surrounding the analysis of dyadic data and reviews selected methods that have been useful in empirical research.

Violations of Independence

Observations or units are sometimes connected, and those connections often come in pairs. Typically, statistics instructors stress the importance of collecting independent data points when constructing statistical tests. Independence makes statistical estimation and inference more tractable, but it may not be realistic in settings involving dyads and groups. Even in basic statistics, there are at least three common violations of the independence assumption in social science studies, two of which are generally well understood. Two data points can be related (i.e., not independent) because they are taken from the same person on the same variable at two points in time. Repeated-measures analyses, time series, and latent growth curve models handle violations of independence due to time. Two data points can be related because they are collected on two different variables from the same person. Correlations, multiple regression, factor analysis, and structural equation modeling are all well-known methods for handling violations of independence due to multiple variables from the same person.

What characterizes these two well-known methods for modeling violations of independence is an appreciation that the violation of independence can illuminate the underlying mechanism. Time series analyses can illuminate how participants grow or change at different rates; correlations between variables can illuminate the underlying factor structure of multiple variables.

The third type of violation of the independence assumption is less well known. Two data points can be related because they are taken from two individuals who are related in some way and can be considered members of the same dyad. For example, the researcher may ask both the husband and the wife how satisfied each is with their marriage. Those two data points are not conceptually independent from each other and so are probably not statistically independent. If the marriage is devoid of intimacy, both partners are likely to report low satisfaction. If the marriage is awash in intimacy, both partners are likely to report high marital satisfaction. Cases where one partner is satisfied and the other not are also interesting. The point is that because both individuals share a common dyadic experience—the marriage—their evaluations of

that experience may be related. Each person serves both as a member of the dyad, or the context, as well as an evaluator of the dyad. If these two individuals are called rater 1 and rater 2, it is easy to see that the two raters can be correlated because they are judging the same object.

Some researchers will either throw away or not collect data from one partner so that analyses can be simplified—with only one observation from each dyad there cannot be a violation of the independence assumption. Although it is true that data deletion simplifies the analysis and preserves the independence assumption, it comes at a very high cost—the researcher is no longer studying the dyad or the influences of social life as dictated by the experience of a dyad.

Statistical Tests and Measures

Association between variables due to dyadic membership can provide an important ground for theory testing. Many methodologists now view dyadic analysis as an opportunity for modeling social behavior. In the early days of dyadic data analysis, the emphasis was in understanding the effect of the independence violation on significance testing. Several procedures were proposed for adjusting *p*-values, for instance, according to the degree of the independence violation. However, methodologists and researchers alike soon realized that this view was shortsighted. An independence violation may not be a problem that needs correcting but rather a diagnostic feature that could be studied to yield important information about dyadic processes.

Fortunately, there has been active development of new statistical techniques for dyadic data. The classic measure of group or dyadic process is the intraclass correlation, developed over 100 years ago. Unlike the usual Pearson correlation that measures association, the interclass correlation measures similarity. A high positive intraclass correlation suggests high similarity between dyad members, a negative intraclass correlation suggests dyadic dissimilarity, and an intraclass of zero suggests independence between the two dyad members.

The intraclass correlation also plays an important role in statistical tests of more advanced regression models applied to dyads. When there are two or more variables collected from each dyad member, then the test of significance between

variables across dyad members, such as the correlation between, say, the husband's satisfaction with the marriage and the wife's commitment to the marriage, is heavily influenced by the intraclass correlation within variables. That is, each dyad member can influence each other on the same variable (e.g., husband and wife satisfaction ratings are likely related) and each dyad member can influence each other across variables (e.g., husband's satisfaction with the marriage related to the wife's commitment to the marriage). The test of significance for the cross variable–cross person correlation (e.g., husband satisfaction to wife commitment) is influenced by the within-dyad correlation on the same variable (e.g., husband and wife correlation on satisfaction).

There are many types of intraclass correlations depending on the nature of design and data. For example, dyad members may be distinguishable on some theoretical basis (male–female dyad members, first born–second born sibling pairs, supervisor–employee dyads, etc.) or the members may be exchangeable in that there is no theoretical basis to distinguish each member with a certain category.

There are several approaches for assessing interdependence for cases where each dyad member provides data, and the research question involves using those data to assess the interdependence of the dyad members. One general approach to estimating the intraclass correlation is the hierarchical linear model, which treats individual dyad members as nested within the dyad. This analysis partitions variability into dyad-level variance (or between-dyad variance) and individual-level variance (or within-dyad variance). The intraclass correlation is the ratio of the dyad variance over the total variance (dyad plus individual variance) in the data. An equivalent way to implement the intraclass correlation is through structural equation modeling, where the dyad is treated as a latent effect. That is, the scores of each individual dyad member are treated as indicators of an underlying latent dyadic variable. The intraclass correlation is equivalent to the square root of the loading for each dyad member (under the constraint that each dyad member has identical loadings). The intraclass correlation can also be estimated from particular analysis of variance designs, and can be directly estimated through a special pairwise correlation setup.

Special Designs and Research Questions

As more variables are added to a dyadic design, richer and more inherently dyadic research questions can be explored. For instance, research questions of social influence between dyad members can be addressed. Does an individual's commitment to the marriage depend more on that individual's own marital satisfaction (an actor effect), or does it depend on the marital satisfaction of the partner (a partner effect)? This type of model is called the actor-partner model because it distinguishes the effect of the target person (the actor) from the effect of his or her dyadic partner. Research questions of shared variance can also be addressed with the latent variable model. This model generalizes the intraclass model by assigning a dyadic latent variable and an individual-level error to each observed variable. Correlations or regression paths can then be estimated between the dyadic latent variables as well as the individual-level error terms. Do shared commitment ratings between dyad members (a dyad-level latent variable) predict shared satisfaction ratings (a second dyad-level variable)? This question reflects a correlation between two dyadic latent variables. Does an individual's unique commitment (defined as unshared, or error variance, because this effect is over and above the shared or dyadic component) correlate with that individual's marital satisfaction? This question reflects a correlation between two individual-level variances. Determining whether processes play out at an individual level, a dyadic level, or both is an important research question about mechanism that will illuminate the study of dyadic processes.

As with all data analysis one needs to be mindful of the type of sample design used on a given research project. Were the dyads randomly selected from a population of dyads and then data collected on each member of the dyad (e.g., married couples randomly selected and both husband and wife provide data)? Is there a set of individuals and is each individual paired with every other possible individual as in a round-robin tournament? A recent research example is a speed dating paradigm where, for instance, 10 males meet with 10 females in all possible cross-gender interactions. Round-robin analyses permit the analyst to separate an observation into different components. Because a

person interacts with every other person, it is possible to disentangle processes related to how others perceive that person and how that person perceives others (very similar to an analysis of variance decomposition into different sources of variance).

Of course, the usual issues that arise in any data analysis situation are relevant in dyadic designs. For instance, the data analyst should check for outliers, reliability of measures, adjust for multiple comparisons, check the equality of variance assumption, deal with missing data, and so on.

Researchers should also be careful that their analyses address their conceptual research questions. This entry has already mentioned how research questions of social influence could be treated through the actor-partner model and how research questions of similarity could be treated through a latent variable approach to dyads. Even the simple index of computing difference scores between dyad members as a measure of similarity is appropriate for some research questions and misleading for others. For example, is the focus on the degree of matching (how close are the dyad members) or on the degree of influence (does one dyad member asymmetrically influence the other)? Different research questions such as these require different methods for handling difference scores in dyads.

Conclusion

The study of dyads presents researchers with an exciting opportunity. All too often nonstatisticians look at the special techniques developed for dyadic data analysis with frustration because their research is now made more difficult. At one conference the authors of this entry heard a prominent dyad researcher shrug his shoulders and say, "I just got nabbed by the independence police." The concern, however, is not that researchers should avoid violating the independence assumption for purely statistical reasons. Rather, for dyads the violation of independence may signal important psychological and interpersonal processes. If scores from two people in the same dyad are related, then there is evidence that there may be some social influence between the two individuals. The underlying mechanism could be interdependence, mutual influence, pressure to conform, or any number of other psychological

processes. Independence violations should be assessed, measured, modeled, and discussed because they provide an important window on social behavior.

DYSSEMIA

A language is a set of symbols whose meanings are agreed on by those who use them. The word *ball* can be used to communicate to others about a ball without actually having that object in hand to show them. The word acts as a symbol or sign for that object. It is easy to understand how verbal language works. Less obvious is that nonverbal signs can function much like words do. For example, just as the word *smile* is a sign for the emotion of happiness, a physical smile is an external sign for an internal state of pleasure or joy. Nonverbal signs can be clearer and more powerful than words, especially when they reflect feelings. Although every verbal language has different words for smile, the actual behavior of smiling is accepted as a sign of happiness across most all cultures and across past and present time. This is known as nonverbal language.

Some people have mild or serious difficulties receiving or sending verbal cues; likewise, some

have trouble receiving or sending nonverbal language cues. Stephen Nowicki and Marshall Duke coined the term *dyssemia* (*dys* = inability; *semia* = to read or send signs) to refer to these deficits. There can be *receptive dyssemias* (difficulties in reading nonverbal cues) or *expressive dyssemias* (deficits in sending nonverbal cues) in any or all of the nonverbal channels. Individuals who have difficulty either reading or sending emotional cues nonverbally are the focus of this entry.

All languages have receptive and expressive components. To receive, one must learn to decipher or decode the meaning of signs and symbols that others send. In verbal language, this means trying to figure out the meanings of written or spoken words. Significant difficulty in accurately reading word cues and signs is called dyslexia (*dys* = inability; *lexia* = verbal signs or words). To express something, one must send or encode meaningful signs and symbols to others. In verbal language, this is done by speaking and writing. Serious deficits in the ability to generate and use appropriate words—for instance, being able to identify fingers on a hand but not being able to come up with the word *hand*—are often called expressive aphasias.

Just as verbal language has receptive and expressive aspects, so does nonverbal language. Receptive nonverbal language skill refers to the ability to accurately perceive the nonverbal cues of others by, for example, looking at their facial expressions or listening to their tones of voice. The important companion skill to receiving nonverbal information is learning to express the appropriate nonverbal cues through a variety of channels.

There are several important differences between nonverbal and verbal communication that can produce significant social impact. First, whenever the verbal and nonverbal messages do not agree in emotional tone, people are more prone to believe the nonverbal one. Nonverbal cues are not only more likely to be believed, they are also more continuous than verbal ones. Paul Watzlawick and colleagues have suggested that “you cannot not communicate nonverbally” (1967, p. 49). There are social implications of the fact that facial expressions, postures, and gestures never stop communicating emotional information.

Compared to verbal communication, nonverbal communication is more likely to take place without people being aware of it. Although people usually are aware of the words they and others use, they often are less conscious of the rich interplay of facial expressions, tones of voice, postures, and gestures that accompany those words.

The impact of rule breaking in verbal communication is different from that in nonverbal communication. When individuals break a verbal rule of language, such as using a singular verb with a plural subject (e.g., “we was there”), they risk evoking a negative intellectual response from others. Someone who makes that kind of mistake may be seen as not very smart or well educated or as emotionally threatening. However, breaking a nonverbal rule of communication usually has a more negative emotional, rather than intellectual, impact on others than verbal errors. People would feel uncomfortable in the presence of someone who is breaking nonverbal rules of communication, but ironically because most nonverbal communication takes place out of awareness, they may not always be aware that they are the source of their own and others’ discomfort. These are individuals who, for example, will sit next to another person in a movie theater even though there are only a few patrons and hundreds of empty seats. Or they will stare too long at someone with little awareness of the discomfort they are producing.

These four differences between nonverbal and verbal communication—nonverbal cues are more likely to be believed, are more continuous, are more likely to take place without our full awareness, and if broken, are more likely to produce an emotional response—provide insight into problems people may encounter in forming relationships. People with dyssemias can provoke negative emotional responses from others, provoke them continuously, and yet be unaware that they are causing these negative reactions. Nowicki and Duke have called this set of difficulties inherent to nonverbal deficits the *dyssemic core*, and they suspect that it causes many personal and social problems.

A final difference between verbal and nonverbal communication is that they are learned in different ways. In contrast to the formal and direct training individuals receive through parents and teachers to

read and write words, nonverbal communication skills are learned indirectly and informally, primarily by watching others. Because educational systems and society give individuals constant and direct feedback about their reading and writing skills, most of them generally know their verbal strengths and weaknesses. It is a much different picture for nonverbal abilities that remain largely unrecognized.

Although Paul Ekman and Wallace Friesen can be credited with introducing nonverbal communication to the field of psychology, Howard Friedman was responsible for emphasizing its role in the communication of emotion, and Robert Rosenthal and his colleagues were most responsible for expanding on this emphasis and in creating one of the most frequently used measures of nonverbal skill—the Profile of Nonverbal Sensitivity (PONS). The PONS was designed to assess nonverbal communication through tones of voice and movement of the face and body presented in film clips. Limitations in nonverbal abilities assessed utilizing the PONS have been linked to interpersonal failures. Nowicki and Duke introduced the Diagnostic Analysis of Nonverbal Accuracy (DANVA) to compensate for shortcomings in previous measures. The DANVA measures the ability to identify and express emotions in facial expressions, tones of voice, and body postures. Individuals who are dyssemic have been found to be less popular at all ages beginning at four, rated lower in social competence by teachers, more likely to have attention deficit disorder, nonverbal and verbal learning disabilities, social anxiety, depression, conduct disorder, psychopathy, and schizotypal personality disorder and speech and language impairment. Dyssemia not only appears associated with personality and social difficulties, but research has found that when intelligence is controlled for, those with problems in identifying emotions nonverbally achieve less than their peers. These findings leave little doubt that nonverbal skill is necessary for social and academic success.

E

EARLY YEARS OF MARRIAGE PROJECT

The divorce rate in U.S. society skyrocketed in the mid-1980s. Given the high rates of divorce, many social scientists became interested in discovering what factors keep married couples together and happy and what factors predict divorce. The Early Years of Marriage (EYM) Project is a one-of-a-kind 20-year study of 373 couples. The project was designed to understand the factors that contribute to the positive development of marital relationships. At the same time, there was an understanding that the processes of marital development might be different in Black American and White American couples. Researchers had studied marriage for decades, but the EYM Project was the first to look at the development of marriage over time for both Black American and White American couples. The study also was designed to examine interpersonal (e.g., communication, conflict) and structural (e.g., economic issues, networks) factors and their connection to marital stability and happiness over time.

The project was initially developed in 1986, by Joseph Veroff, Elizabeth Douvan, and Shirley Hatchett, at the University of Michigan's Institute for Social Research. Joseph Veroff and Terri Orbuch have directed the project into the 1990s and beyond. This entry provides a general overview of the EYM Project and its contribution to the literature on marriage and divorce.

Who Participated in the Study and How?

The study began with a sample of 373 married couples (199 Black American; 174 White American), all of whom had applied for marriage licenses in Wayne County, Michigan, during 1986. To be eligible for the study, both members of the couple had to be of the same race, in their first marriage, and the wife had to be younger than 35 years of age. All eligible Black American couples and a random sample of White American couples were contacted and asked to participate. Of those contacted, 66 percent agreed to participate, a reasonably good response rate.

The couples were interviewed on multiple occasions. The first interview took place a few months after marriage, a time when most couples are firmly in the glow of the honeymoon period. Married couples were re-interviewed in Years 2, 3, 4, 7, and 16 of their marriages. All respondents, married or divorced, participated in a brief survey in Year 14. In Years 2 and 4, brief telephone interviews were conducted. In Years 1, 3, 7, and 16, married couples were interviewed at their homes by a race-matched interviewer. Each individual was interviewed separately and then with his or her spouse. In Year 16, for the first time, interviews were conducted separately with respondents who had divorced over the years.

Many different methods were used in the interviews. In the couple interview, spouses were asked together to tell the story of their relationship in narrative form. A behavioral observational procedure having them resolve differences about the

important rules for a good marriage also was used. In the individual interviews, a variety of questions were asked on topics such as marital happiness, family of origin, religion, employment experiences, housework and childcare, children, and perceptions of discrimination (Black Americans only).

It was extremely important to the goals of the project to obtain marital status and contact information on everyone from the original sample, whether married or divorced. Therefore, in Years 14 and 16 of the project, extensive telephone and field tracking took place to locate and obtain information on all members. For those individuals who could not be located, divorce records were searched from surrounding counties.

To compare the EYM sample with national statistics, the researchers used the General Social Survey (GSS) data from 1980 to 1994. After dividing the GSS sample into Black Americans and White Americans, and selecting out individuals by marital status (first married) and age (for the EYM range of 25–37 years), the sample was found to be consistent with national norms for first married individuals by race on income, education, parental status, likelihood of cohabitation, and a host of other demographic factors.

Several features of the EYM Project enhance the significance of the research project and findings: (a) the reasonably large sample size, (b) the analysis of both Black American and White American couples, (c) the continuous collection of data from both husbands and wives over 16 years, and (d) the ability of the researchers to locate and interview a high percentage of the original respondents in all years of the study.

Divorce Rates

A common question concerns the divorce rates in each year of the project and whether these rates differ for Black American (BA) and White American (WA) couples. In the 3rd year of the study, 14 percent (9 percent WA, 18 percent BA) of the original couples had divorced or separated; in the 7th year, 29 percent (20 percent WA, 37 percent BA) were divorced or separated; in the 14th year, 41 percent (30 percent WA, 50 percent BA) had divorced or separated; and in the 16th year, 46 percent (36 percent WA, 55 percent BA) had

divorced or separated. Thus, Black American couples were about 50 percent more likely than White American couples were to divorce or separate during the first 16 years of marriage. These divorce rates are consistent with other findings in the literature. The EYM project's tracking procedures and efforts were successful over time: The project was able to gather marital status information on 98.9 percent of the original sample, an exceptionally high rate for research of this sort. Very few respondents refused to participate in the study once they began the project.

Important Findings and Contributions

The EYM Project has been the catalyst for many scholarly publications. Two major books also have been written from the data. A list of current publications is available on the project Web site (<http://projects.isr.umich.edu/eym>). Many conceptual and methodological questions about marriage, parenthood, families, and divorce can and have been addressed using the EYM data. The following topics illustrate but do not exhaust the possibilities.

The project data are useful for describing couples in early marriage and over time. For example, about 55 percent of the Black American couples and 22 percent of the White American couples had children before marriage. About 65 percent of the Black American couples and 41 percent of the White American couples had cohabited before marriage. Moreover, more than 45 percent of the couples shared their home with others, usually their children, but sometimes with other adults as well. Also, wives were more religiously observant than were their husbands in all years of the study.

The project data also are valuable for understanding and identifying the factors that influence marital stability and quality over time. Given the project's focus on both structural and interactional factors, the data can identify whether and to what extent oppressive social conditions (e.g., low income, unemployment), challenges of parenthood and family responsibilities (e.g., childcare issues, network support), and interactive processes between spouses (e.g., conflict, sexuality) are critical for maintaining a marriage over time. Given that these data are longitudinal, it is also possible to examine whether spouses' earlier adaptation to

each other (e.g., integration of work and family roles) has consequences for long-term individual, marital, and family outcomes. For example, project findings suggest that all couples need to resolve several critical problems of adaptation in the early years of marriage. When couples are able to reconcile these challenges (e.g., weaving social networks, negotiating the world of work, becoming parents, and managing conflict), they are happier and more likely to stay together over time.

Another way to understand marriages over time and the factors that determine marital quality and stability is through the lens of race/ethnicity. Until recently, the vast literature on marriage and divorce emphasized White American marriages. Little attention had been given to Black American marriages and even less to divorce within the Black American community. The EYM Project is distinctive because project findings demonstrate that the racial/ethnic context of marriage is critical to understanding the meaning of marriage in the lives of individuals and couples. For example, Black American husbands are more egalitarian in their gender roles and are more likely to help around the home and with children than are White American husbands. Black American husbands' participation in home labor is important to Black American marriages because it reduces the risk of divorce. Husbands' participation in home labor is not predictive of the risk of divorce for White American couples. The effects of race on the risk of divorce and marital quality are not explained away by the introduction of interactional (home labor, conflict) or structural (education, income) variables.

Race/ethnicity also must be considered through the lens of gender. Even the experiences of being male or female in a marriage have unique meanings depending on whether one is Black American or White American. For example, wives' greater educational attainment protects couples from divorce, regardless of race. However, the risk of divorce does not go down for Black American husbands with increased education as it does for Black American wives and White American husbands and wives.

Extensive project data were gathered on divorce in Year 16, so the context of divorce for both White American and Black American individuals also can be tied to qualities and conditions of the earlier marriage. For example, outside factors (e.g., networks, work demands) are tied more to the stability of

Black American couples than of White American couples, whereas internal factors (e.g., commitment, managing conflict) are more tied to the stability of White American couples than of Black American couples. More specifically, husbands' concern about financial security predicts marital instability among Black American couples, but not among White American couples. In contrast, factors of conflict management are predictive of marital instability among White American couples, but not among Black American couples. A couple's position in the larger society can determine what marital factors are important in determining marital stability and quality.

Lastly, the EYM Project examines the nature of reconstructive memory for relationship development through a narrative technique that asks couples together to tell the "story of their relationship." Couples and individuals told stories of the development of their marriage, the birth of a child, and the divorce experience (if divorced) at several points in the project. These stories were coded and content-analyzed for their role in predicting marital, family and individual well-being over time. For example, for the majority of the couples, the courtship story was a collaborative effort between husband and wife, rather than a story told primarily by one spouse or the other. Also, for all but Black American husbands, having told their courtship story with some amount of conflict was indicative of lesser marital happiness. Not being able to agree easily on the story of the courtship early in marriage has long-term consequences for marital happiness.

Conclusion

The EYM Project is a unique study that follows a large and diverse sample of married couples over time. The researchers continue to track and make contact with all EYM respondents. The researchers send out a newsletter and an update form each year to all respondents and encourage respondents to update their contact information (and changes in marital status) via the project Web site. The researchers look forward to collecting additional data from all the original EYM participants in Year 25 of the project.

ECONOMIC PRESSURES, EFFECTS ON RELATIONSHIPS

Economic pressure is an emotional, cognitive, and behavioral response experienced by family members who have had economic problems in their daily lives. How family members react to economic pressure depends on factors such as the type of pressure, the individual reactions, the type of economic problem, and the interaction of family members to each other. Glen Elder, a sociologist, along with his colleagues over the years, has studied economic pressure. Rand Conger and his research team have continued the investigation of

these concepts and have placed them within a family stress model. Other fields such as family economics, family studies, and consumer economics have also studied these concepts, but using the components and frameworks of well-being rather than a pressure and problem orientation. When several fields look at different parts independently, it adds to the complexity of describing a phenomenon. This entry describes what types of economic problems cause economic pressure, the source of problems, and the influence of economic pressure on family relationships.

Types of Problems Causing Economic Pressure

The same level of income is not viewed the same by every family. The amount of money brought into the family is only part of this complex issue. Many people study economic problems using an “income-to-needs” concept. This refers to the amount of money available to be used divided by the number of people who are dependent on the income available. The concept of available income has a connection to relationships and the family structure. In some families, it is assumed that the money is a shared resource and used for the goals, needs, and problems of the family unit. In other families, it is assumed that the earner has the control of how or whether the income is shared. Most of these situations occur in family units where they believe being independent is the way to approach daily life. This is often ascribed to in European-American cultures.

Economic problems vary by several factors such as the age of the earner, the responsibilities of the earner, who is dependent on the income (another adult, a child, other people), and how many earners are in the unit. Factors that relate to the economic problems or lack of economic problems are sometimes influenced by the characteristics of the person earning the money. The health (including mental and physical), the education, and skills of the earner all influence the level and stability of the earnings.

People also study the decision-making processes of the family members who have access to the income. What are the decisions around the “how” and under what circumstances can different types of money be used? For instance, is the family unit’s

rule to “never spend more than what is available to use” or “no matter the level of income, one must always save something”? Is it “okay to use the marketplace and credit to get what you want” or it is “only acceptable to use the marketplace and credit when it is an absolute need for the family?” The complexity surrounding these issues varies across the structure of the family organization and within each family type across a life span. These rules along with the level of income can be viewed as contributing to economic problems resulting in economic pressure, especially if not all members of the family agree with the rules. If the rules can’t be followed because of situations beyond the control of the family, this also contributes to problems.

Economic Pressure From External or Internal Economic Problems

Many families have economic problems that occur outside their family context and are often out of their control. These are things like changes in the job market, a natural disaster, a human-made disaster with social unrest, a car accident, or a death. All of these result in the loss or reduction of earning power, or the loss of the earner. However, for many families, economic problems are a result of things inside of their family context. Poor relationships that lead to a divorce, bad judgments around risky behaviors that lead to the earner not being able to earn, or parent-child discord often create added demands on the amount of money available. Another set of internal economic problems come from the dynamics within the family. Individuals and thus families that have built the ability to communicate about daily life, hold the attitude that trying something new and different is okay, have hope for tomorrow, or are creative will be able to weather some of the pressures that come from economic problems. In other words, people who have the ability to use all resources available to them, in addition to money, may have fewer economic pressures. In addition, a family unit that is tightly knit and emotionally connected is generally better able to find solutions, including economic ones, that reduce pressures coming from economic problems.

Influence on the Family Unit

Economic problems influence relationships within the family. Much of the research has been done on small groups of couples. Adverse pressures (high economic pressure) have been documented in middle-income families as well as in low-income families. However, over time the most pressure comes from either the change in the economic situation or change in the relationship. The level of income is not the main source of economic pressures. If the cause of the pressure is external (e.g., economic disaster) and a large economic problem occurs such as bankruptcy, the ultimate impact on relationships depends on age, skills and capabilities, and if earning power is reduced. When the pressure is internal (e.g., poor consumer purchasing, risky behaviors that have financial consequences), the impact on relationships also depends on the age of the earner, the dynamics of the people who helped to create the internal pressure, the recovery ability of people, and whether the earning power has been influenced by health or death. Younger people have better ability to recover whereas older people are less likely to recover. Strong family relationships tend to have the power to withstand the pressures and correct or mitigate the long-term effect of the problems. Children growing up in households that have economic pressures are most influenced when the economic problems are long term. Sometimes the influence leads to problems such as difficulty in learning, school attendance, or behavior problems. It also leads to fewer opportunities for children. Younger children show the least consequences of economic pressures, whereas older children, especially adolescents, show the most. Boys retain the consequence longer into adult life than do girls. When the pressures are great enough to separate the family unit, commonly through divorce, some children show long-term consequences.

EGALITARIAN RELATIONSHIPS

Egalitarian relationships are those in which partners equally share all benefits, burdens, and responsibilities. Although, in theory, the notion of an egalitarian relationship could apply to any dyadic relationship, such as friend, sibling, or coworker, research has focused primarily on married men and women. No good estimates of the percentage of egalitarian marriages exist, but it is widely agreed that gender inequality is the norm in married couples. Egalitarian relationships are in the minority. The purpose of this entry is to define *egalitarian relationships*, to discuss the hypotheses that account for them, and to foretell their future.

Egalitarian relationships are found among couples of varying class backgrounds, albeit in different forms. An egalitarian college professor and dentist might work together to get their kids up, dressed, fed, and off to school; alternate after-school pickups; and share the evening cooking and cleanup, homework help, and bedtime routines. They might rely on some paid household labor. An equally sharing nursing assistant and carpenter, however, are less likely to hire household help, and chances are that they would be among the many dual-earner couples who work different shifts and alternate caring for their children.

Shared power and shared domestic labor are two key aspects of egalitarian marriage. Studies of decision-making power in marriage typically find that husbands and wives whose incomes are relatively similar are more likely than are other couples to have equal say in important decisions. Husbands and wives in egalitarian relationships vary in the extent to which they equally divide the same tasks or specialize in particular tasks, but time in domestic labor is shared equally as is the onerousness of the tasks assumed.

Three hypotheses have spawned a large body of research on the predictors of the division of family labor: relative resources, time availability, and gender ideology.

The relative resource hypothesis starts from the assumption that housework and childcare are unpleasant burdens, which married partners try to avoid. The partner with relatively more resources will use them to negotiate a relatively smaller share of household labor. The time availability hypothesis posits that the distribution of domestic labor reflects who has the time to do the work; the more time either spouse spends in the labor force, the less time she or he will contribute to housework and childcare and the more the spouse will do. The gender ideology approach argues that beliefs about gender equality shape the division of domestic labor; the more husbands and wives believe that men and women should have similar roles in paid work and at home, the more they will share housework and childcare.

Each of these hypotheses has garnered some support, but has also been challenged. For example, income is indisputably a resource associated with a smaller share of household labor, but education is sometimes associated with men doing a larger share of domestic labor, the opposite of what would be predicted if education were used to bargain oneself out of domestic work. The time availability hypothesis begs the question of how decisions are made to allocate each spouse's labor to the market. The biggest problem of all three approaches is that they ignore that gender itself affects each of these proposed influences on the division of family labor. Income may buy spouses out of housework, but in most American families, the reality is that each dollar a woman earns tends to buy less time off than each dollar a man earns. Likewise, time availability for household work depends on gender. Given the same paid work hours, women do more domestic labor than men do. As for gender ideology, some studies show that the division of household labor is more equal when men believe in equality but not when women do. Perhaps most problematic, even when husbands and wives earn equal incomes, spend equal time in the labor force, and believe in gender equality, the division of household labor is still usually unequal.

In response, gender constructionists have argued that the tenacity of the unequal division of domestic

labor stems from its importance for establishing gendered identities for both men and women. In a few studies, women whose income exceeded their husbands' actually increased their housework contribution, presumably to compensate for the threat posed to their own and their husbands' gendered identities. The more egalitarian divisions of labor among gay and lesbian couples also speaks to the centrality of gender in establishing an unequal division of household labor in heterosexual married couples. Some might argue that gender socialization shapes preference and skill, which then makes it simply rational for couples to specialize in what they are good at. However, household skills, such as using a washing machine, can easily be learned. Likewise, many new moms today have little experience with infants, but quickly become skilled because of their intensive experience with their newborns. Men's invoking their lack of skill is more of a strategy for excusing themselves from domestic labor than an explanation for why they are not involved. Specialized trade-offs could be egalitarian when they meet the time/task criteria, but they do not if men's labor is limited to stereotypically male tasks.

Although household labor and decision-making power are the most researched components of egalitarian relationships, the distribution of other benefits, burdens, and responsibilities also go into creating equality in couples. For example, spouses may have unequal and hidden power to bring up issues for discussion; they may differ in doing the emotion work that goes into maintaining their relationship, and even when they equally share time in housework and childcare, they may take unequal responsibility for making sure the job gets done and for the mental labor that goes along with that responsibility (e.g., keeping track of when the next dentist appointment should be made or whether there are diapers in the house). Likewise, even when both spouses work full-time for pay, they may differ in felt responsibility for breadwinning.

Egalitarian relationships have been associated with a variety of positive outcomes, including marital satisfaction, less depression for wives, and less conflict between spouses. Although past studies suggested that these outcomes only obtained for those who believed in gender equality, some recent studies in places as diverse as the United States and Taiwan have found equality to be

generally beneficial, with especially enhanced outcomes for those couples who believe in gender equality. Of course, we do not have data from some of the most traditional gendered societies to know how couples would fare if egalitarian.

Gender is changing. During the past 40 years in a wide range of countries, couples have become increasingly egalitarian. Women have entered the labor force in dramatic numbers. The discrepancy between men's and women's housework and childcare has slowly but steadily decreased. Belief in egalitarian relationships has become commonplace in the United States. Although still in the minority, the percentage of egalitarian relationships is growing. Gender equality in the workplace and egalitarian attitudes have promoted this increase, but the everyday negotiations between spouses over housework, childcare, leisure, and power are also critical. Everyday interaction between spouses is the process by which the ideals of gender equality are translated into the reality of egalitarian relationships.

ELDER ABUSE AND NEGLECT

In the 2006 national report on elder abuse and neglect by Pamela Teaster and colleagues, Adult

Protective Services (APS) received 381,430 reports on people 60 years of age and older. In most states, APS is the agency to which people first report abuse or neglect of older adults. These forms of mistreatment are highly likely to be underreported for many reasons: Older adult victims may be unable to report because of mental or physical problems, elders fear stigma and retribution by their caretakers, and persons who might report on behalf of an alleged victim (e.g., doctors, nurses, social workers, concerned family or friends) perceive that APS programs have inadequate resources and make inappropriate responses.

Ten years earlier, APS received 293,000 domestic reports of elder abuse. Comparing the number of reports over time suggests a rise of 30 percent over the past decade. Reasons for the increase are unclear. The increase could be attributed to the larger population of older adults, greater awareness of elder abuse and neglect, a higher number of agencies to address these problems, or a combination of these and other factors. This entry facilitates understanding the history and scope of elder abuse and neglect through a historical overview, definition of types of elder abuse and neglect, and an analysis of the scope of the problem.

Elder Abuse and Neglect Situated in Time

Unfortunately, but not surprisingly, accounts of elder abuse and neglect exist early in human history. Ancient Greeks believed that parricide, or the murder of parents, was necessary to ensure that civilization continued. Fairy tales are replete with stories of young persons prevailing over wicked crones who cast evil spells (e.g., *Snow White*, *Beauty and the Beast*, *Rapunzel*). During colonial times in the United States, the treatment of elders was synonymous with the treatment of persons with mental illness. Elders, particularly those persons with mental illness or dementia, were forced to wander from town to town. Even the Salem witch trials of the late 1600s involved an element of elder mistreatment, as many of the people who were burned at the stake or who endured other torture were regarded by the community as “old” or “different.” The issue of elder abuse is mentioned little, however, in the late

19th and early 20th centuries because elders were of little interest to society.

Research on elder abuse and neglect had its genesis in the late 1960s and was conducted to increase public awareness and development of relevant policy, clarify definitions, and provide assessment and screening tools and promising intervention practices. Although we know more about elder abuse and neglect than ever before, we still do not know its scope, which makes action related to the problem difficult to justify. The only U.S. prevalence study ever conducted remains that of Karl Pillemer and David Finkelhor, a study conducted in Boston in 1988 that did not include financial exploitation in its estimate of prevalence. That study suggested that only 1 in every 14 instances of elder abuse is reported, so there may be as many as five million cases of elder abuse occurring in a given year.

The Issue of Definitions

The National Center on Elder Abuse (NCEA) has identified seven types of elder abuse: physical abuse, sexual abuse, emotional abuse, financial exploitation, neglect (by a caregiver), abandonment, and self-neglect (neglect by the victim of him- or herself). Many different patterns occur. For example, an elder may encounter one type of abuse as a single, distinct incident involving one perpetrator, or he or she may experience multiple types over time that are committed by multiple perpetrators.

Physical abuse, or the use of physical force resulting in bodily injury, physical pain, or impairment, may include acts of violence such as striking (with or without an object), hitting, beating, pushing, shoving, shaking, slapping, kicking, pinching, and burning. It may also include the inappropriate use of drugs and physical restraints, force-feeding, and physical punishment. In the Teaster study mentioned earlier, physical abuse constituted 10.7 percent of all substantiated or confirmed abuse.

Sexual abuse, or any kind of nonconsensual sexual contact, includes unwanted touching and all types of sexual assault or battery, such as rape, sodomy, coerced nudity, and sexually explicit photographing. In the recent national study, sexual abuse constituted 1 percent of all substantiated abuse.

Emotional or psychological abuse, or the infliction of anguish, pain, or distress through verbal or nonverbal acts, may involve verbal assaults, insults, threats, intimidation, humiliation, and harassment. Emotional or psychological abuse constituted 14.8 percent of all abuse substantiated by APS.

Financial or material exploitation is the illegal or improper use of an elder's funds, property, or assets. Exploitation constituted 14.7 percent of substantiated reports.

Neglect is regarded as the refusal or failure to fulfill any part of a person's obligations or duties to an elder. It may also be failure of a person who has money-related responsibilities to provide care for an elder or failure of an in-home service provider to provide necessary care. *Abandonment*, often associated with neglect, is the desertion of an elder by a person who had assumed responsibility for providing his or her care, or by a person with an elder's physical custody. About a fifth of substantiated APS cases (20.4 percent) cases involved caregiver neglect or abandonment.

Self-neglect is behavior of an elder that threatens his or her own health or safety. Some self-neglectors refuse or fail to provide themselves with adequate food, water, clothing, shelter, personal hygiene, medication, and safety precautions.

Many substantiated APS cases involved self-neglect (37.2 percent).

The NCEA definitions remain those predominantly understood by people who work in the field, although many researchers now use those established by the National Academy of Sciences (NAS) in 2003. As explained by Richard Bonnie and Robert Wallace in their 2003 report, the NAS panel of experts helped resolve problems created by inconsistent definitions of types of elder abuse and neglect. They conceptualized elder mistreatment as different from elder abuse by excluding self-neglect and exploitation committed by a person or entity unknown to the victim. The NAS panel defined elder mistreatment as intentional and unintentional acts of harm by a trusted other.

Efforts to establish clear definitions continue as people who work directly with elders and scholars who study elder abuse and neglect seek a commonly held set of definitions to accurately quantify the phenomena. If it is possible to reach consensus on definitions, it will be far easier to justify policies and programs aimed at helping affected elders and their families. While experts pursue agreement on definitions and work to identify prevalence, one fact is certain: Abuse of elders continues. The following specific information about elder abuse and neglect comes from the study by Teaster and colleagues.

Figure 1 Substantiated Reports by Category for Adults Aged 60+ ($n = 19$ states)

Source: Teaster et al. (2006).

Impact of Abuse

Although our understanding of elder abuse is in its infancy, vulnerability appears to be a risk factor. Elder abuse and neglect typically involve older Caucasian women living alone or with family members. Victims are vulnerable because of physical frailty resulting from multiple chronic illnesses. They are vulnerable because they are often also experiencing depression, dementia, or both. These conditions can be socially isolating and create situations in which elders need others for help.

The affected elders. Findings from the 2006 Teaster study revealed that 65.7 percent of victims were female. More than 20 percent (20.8 percent) of victims were between the ages of 60 and 69, 36.5 percent were 70 to 79, and 42.8 percent were 80 years of age and older. The majority of victims

were Caucasian (77.1 percent), followed by African Americans (21.2 percent), American Indians and Alaskan Natives (0.6 percent each), and persons of Asian descent (0.5 percent).

The settings of abuse. The overwhelming majority of substantiated reports occurred in domestic settings (89.3 percent). Approximately 6.2 percent of substantiated reports occurred in long-term care settings, with 1.8 percent situated in other locations, including hotels or motels, the workplace, and assisted-living facilities. Many APS programs do not investigate abuse in long-term care facilities; therefore, this number is likely lower than the actual incidence. Responsibility for investigating in long-term care facilities is often given to other entities (e.g., local long-term care ombudsman, survey and certification agencies, and Medicare Fraud Units). Entities responsible vary significantly from state to state and by type of facility. This variability makes collecting reliable numbers difficult.

The perpetrators of abuse. More than half (52.7 percent) of alleged perpetrators of abuse of elders aged 60 or older were female (47.3 percent male); 31.0 percent were under 39 years of age, 44.1 percent were between 40 and 59 years of age, and 24.9 percent were ages 60 and older. The most common relationship of perpetrator to victim was that of adult child (32.6 percent), followed by other family member (21.5 percent), unknown relationship (16.3 percent), and spouse or intimate partner (11.3 percent).

Perpetrators abuse for a variety of reasons. Some are poor caretakers who lack the ability and skills necessary to care for a person with mental or physical illnesses. Many abusers are dependent on an elder in some way. They may need a place to live, and the elder can provide that place. Instead of feeling grateful, a perpetrator may resent the elder and try to push her out of her own home or isolate her within it. Abusers may need an elder's money. Initially, they may promise to pay the money back, but over time, they regard the money as something to which they are entitled or will get anyway once the elder dies. Abusers may need the elder for access to alcohol, drugs, sex, or all of these. Some perpetrators mean to swindle older adults out of their possessions through scams.

Finally, some perpetrators, particularly those who are mentally ill, seek power and control over a person they regard as vulnerable.

In summary, elder abuse appears to be a growing phenomenon. Vulnerability is a risk factor for abuse. Abuse appears to involve more older women than older men, but men are also targets of abuse. Abuse tends to involve more non-Hispanic Caucasian women than any other racial or ethnic group. Most perpetrators are family members. Regardless of the reasons that perpetrators abuse, it is a crime in many cases and unethical and immoral in all.

The costs of elder abuse at individual and societal levels are great as elder abuse diminishes us all. Families and friendships are fractured forever. Abused elders may need invasive and expensive health care. Because of physical and emotional injuries, many elders are plunged into despair and experience an untimely and hastened death. Also as a result of abuse, some elders lose all their civil rights through the appointment of a guardian. Many entities that help are funded largely through tax dollars so that they may protect and intervene when vulnerable elders are abused. These interventions often entail assistance involving multiple and costly services that must be provided for the rest of an elder's life. Millions of dollars are taken yearly from vulnerable elders, costs that are then passed on to others through increases in insurance payments and taxes, not to mention the individual and hidden costs to family members and friends who must help out by using their own money and time.

Despite efforts to increase research and public awareness, compared with child abuse and intimate partner violence, funding related to elder abuse is low. An infusion of dollars on local, state, and national levels is critically needed to address the problem comprehensively and successfully.

EMBARRASSMENT

Embarrassment is the involuntary, uncomfortable emotion that results when social predicaments increase the threat of undesired evaluations from other people. It usually strikes without warning when people suddenly realize that they are making (or are about to make) an unwelcome impression on others as a result of some misstep. This causes feelings of startled surprise, awkwardness, and sheepish abashment and chagrin; embarrassed people typically feel conspicuous and clumsy, and they are mortified by the unwanted judgments they expect to receive.

Studies of embarrassment are pertinent to human relationships in several ways. First, they delineate fundamental motives that underlie our dealings with others. Second, in describing the diverse ways in which interactions can go awry, studies illustrate the delicate complexity of social life. And third, they provide an intriguing example of the use of an evolutionary perspective to account for modern behavior. This entry discusses all three of these.

Fundamental Motives

Our species exhibits a *need to belong*: We thrive when others accept us, and we suffer when others reject us. As a result, we routinely monitor what others are thinking of us, and we work to maintain desired images of ourselves for those whose judgments we value. The prevailing view of most

theorists is that embarrassment operates as an alarm mechanism that helps us deal with untoward events that might engender social rejection. It occurs automatically to interrupt inept behavior and to promote remedial action when self-presentation fails and we face the dreadful prospect of undesired social evaluation.

Indeed, embarrassment depends on our ability to imagine what others may be thinking of us. People who are unable to comprehend what other people think of them—such as young children, autistic adults, or anyone with certain types of brain damage—are hard to embarrass. They have difficulty understanding others' points of view, so they may remain calmly unruffled in awkward situations that would discombobulate the rest of us. Only when their cognitive abilities are sophisticated enough to allow them to see things from others' perspectives (beginning around 10 years of age) do children begin to be embarrassed by some of the same subtle situations that embarrass adults.

Embarrassment is also rare when people genuinely do not care what a particular audience thinks of them. It is more frequent and more acute when people are especially sensitive to other's opinions. In particular, those who chronically yearn for acceptance and dread social disapproval react more strongly to social predicaments than others do.

Thus, we normally possess hardwired (innate) responses that occur uncontrollably when our motives to maintain desired images for others are thwarted. When embarrassment strikes, a distinguishing pattern of cardiovascular and adrenal arousal unfolds; notably, when dilation of capillaries in the face brings blood closer to the surface of our cheeks, we blush. This is a distinctive physiological reaction that is usually accompanied by a characteristic pattern of nonverbal behavior in which people avert their gazes, touch their faces, bow their heads, and try (but usually fail) to suppress sheepish grins that are recognizably different from smiles of real amusement. All of these reactions typically make a person's embarrassment easy to detect, so embarrassment affects our interactions with others, too.

Interactive Complexities

Most of the events that cause us embarrassment are individual blunders in which, all on our own,

we publicly rip our pants, stall our cars, or forget others' names. However, our relationships with others make a variety of more complex predicaments possible. When we find someone else in a humiliating situation, we can experience *empathic embarrassment* if we envision what that person is feeling. If a relationship partner misbehaves, we can suffer *team embarrassment*—being abashed by our acknowledged association to the wayward partner—even when we have personally done nothing wrong. Intimacy with others also increases the chances that they will accidentally embarrass us by *privacy violations* in which they inadvertently reveal secret or sensitive information about us to others. And on occasion, we may become the unwitting victims of *intentional embarrassment* when others make us the butt of practical jokes.

Intentional embarrassment can make the embarrassed victim angry, but most episodes of embarrassment elicit other reactions. People are sometimes so flustered by their predicaments that they simply run away, but they are more likely to (try to) ignore the incident and pretend that nothing has happened. If embarrassed people do mention the event, they often do so with humor if no harm was done, and if others were inconvenienced, they frequently apologize and take action to repair any damage. Thus, more often than not, embarrassment leaves us contrite, humble, and eager to please. Embarrassed people routinely behave in conciliatory ways that are likely to deflect disapproval from others.

One of the most remarkable things about embarrassment is that once some predicament arises, others will like us and treat us better if we do become obviously embarrassed than if we remain coolly unperturbed. Studies routinely find that people who are obviously chagrined after some maladroit mishap receive more favorable evaluations than do those who implacably stay cool and calm. Embarrassment that is calibrated to one's circumstances, being neither too extreme nor too mild, routinely elicits sympathy and support from bystanders. (This isn't true among children, where goofy mistakes are often met with ridicule and derision; among adults, however, kind responses are the norm.) People who are inconvenienced by our mistakes may be annoyed by our actions, but even then, our embarrassment demonstrates that we recognize and regret our

transgressions, and that portrays us in a favorable light.

An Evolutionary Perspective

When embarrassment occurs, it is usually obvious, and, because a blush cannot be faked, it demonstrates that our abashment is authentic and our contrition sincere. That may be why others then typically respond in a kindly fashion; one's embarrassment reassures observers of one's good intentions. Thus, embarrassed emotion may have evolved as a social communication that helped to forestall social rejection that would have reduced one's chances of survival in harsh ancestral environments. Embarrassment may exist because humans are social animals who thrive only when they can comfortably coexist in close contact with others.

EMOTIONAL COMMUNICATION

Emotional communication refers to the process of using messages to exchange information about and to influence each other's emotional states. Messages may be direct verbal and nonverbal expressions of emotion (e.g., smiling and saying, "I'm so happy!"), but more often, the messages are complex and subtle, and emotional states are more elusive (e.g., "He seemed kind of fidgety or

worried later in the meeting”). Messages may function to share information (e.g., “I am feeling so sad!” while crying) or to influence the emotions of others, as with warnings (e.g., “Be afraid!”) or advertising (e.g., “Feel good about this product!”). In a sense, all communication is emotional, though by varying degrees.

Being aware of how other people feel and how they are intertwined emotionally is essential to interacting and relating with others effectively. People are more likely to offer support if they see another person in distress or to tread lightly if they know that another is in a bad mood. Mutual emotional attunement is one of the hallmarks of close relationships. In early life, healthy attachment depends on caregivers recognizing and responding to the emotional needs of infants; conversely, unhealthy patterns can develop when infants respond to their caregivers’ depression. For older children and adults, intimacy means, at least in part, emotional sharing and concern for each other’s emotional needs. This entry discusses a number of topics about emotional communication, including the ways in which emotion and conversation are intertwined, distinctions between emotional expression and emotional communication, the accuracy to which emotion is communicated, and emotional competence in a relational context.

Communicating Emotions, Feelings, Moods, or Equanimity

Scholars offer a wide variety of definitions of emotion, and there is no clear dividing line between emotions and related internal states and experiences such as thoughts, judgments, instincts, or bodily states. Some of the best candidates for emotion are love, joy, fear, anger, sadness, shame, and disgust because they represent large linguistic categories or because they are associated with distinctive facial expressions. Sometimes what is communicated is a feeling or mood, both of which are positive or negative emotion-like states but not full-blown emotions. Even the absence of apparent emotion can carry important information, as when someone is described as calm under pressure or numb after hearing devastating news.

Individuals, families, cultures, and historical periods vary in the frequency, intensity, and nature

of emotional expressions. Some individuals are more dramatic in their expressions; others are more subtle. Some families value emotional spontaneity; others value emotional control. Some cultures use a specific emotion term often, but others use it rarely (e.g., *shame* in Mandarin Chinese versus in American English). A word that was in circulation at one time may go extinct (e.g., *accidie*, meaning reluctance to fulfill one’s religious obligations, or *sloth*), or an emotion that was once valued may fall into disrepute (e.g., *jealousy*).

Cues and Channels

Cues to emotion are plentiful and varied. Facial expressions, down to specific muscles, have received a great deal of research attention, but vocal cues such as pitch, volume, and timing have also been studied in depth. Less well understood are bodily cues such as posture, movement, and gestures. Verbal expressions of emotion span a huge range of possibilities including emotion words, epithets, phrases that reveal underlying metaphors, utterances in conversations, poetry and prose, stories, and even patterns of public and private discourse that vary across cultures and historical periods.

Yet emotions are rarely the primary message. Because emotions are almost always *about* something, emotional expressions are nearly always intertwined with the content of the message or the social episode that is unfolding (e.g., “I am angry about what you just said” or “What a fabulous weekend I had!” [which explains why I am so cheery]). In addition, the emotions expressed may or may not be the emotions actually felt (e.g., “I am pretending to be angry about what you just said, but I actually have to hold back my laughter”). Emotion may be a constant subtext in conversations in the sense that people may continuously monitor the other’s feelings as the social interactions unfold, or at least they may be tuned to notice changes or more obvious expressions.

Another way in which emotion and conversation or other forms of discourse are intertwined is that people talk about emotion (e.g., “Could you believe his emotional outburst?”). In private and in public, many aspects of emotion and its expression undergo scrutiny: What was she feeling? Why?

Was it justified? Was it appropriate? What was the purpose? What will be the consequences? In a sense, our emotions are not just our own business, because when they are expressed they can become everybody's business.

Intention and Audience

The terms *emotional expression* and *emotional communication* are used almost interchangeably in the research literature, but the slight difference in meaning underlies a complex view of how emotion works. Early work focused on *emotional expression* and was based on the assumption that facial, vocal, and other expressions directly reflected a covert emotional state that was "pressed out" for others to observe. Darwin believed that emotional expressions evolved from the essential functions of emotions themselves, such as when the disgust facial expression mimics the expulsion of disgusting substances from the mouth. The evolutionary advantage of expression is that when others become aware of emotional states, they may take heed, provide assistance, steer clear, or otherwise adjust. The survival advantage of emotional expression for helpless infants with devoted caregivers is obvious, as is the reproductive advantage of knowing when a potential partner is interested.

Emotional *communication* becomes relevant with three additional properties of human emotional expression. First, most cues are controllable—not all, but nearly all. The muscles that make the corners of the eyes crinkle with felt joy but not fake joy are one exception. Blushing may be another, but common expressions like smiling, yelling, crying, hitting, and hugging certainly are controllable, at least most of the time, although emotional control is a skill that develops with practice and may break down under stress. Because most cues are controllable, the choice not to control emotion is also a kind of control (e.g., "I'm going to really let loose with this tantrum!").

Second, people know others may be observing their emotion and expressions, and often people want others to know how they are feeling. In fact, the show may go on only if there is a sympathetic audience, as when children's distress disappears when a parent leaves the room. This is what is ordinarily meant by emotional communication,

that is, the intentional transmittal of cues meant to inform others of one's actual emotional state. Awareness of impact on others combined with control means people can be emotionally deceptive; they can fake happiness at a wedding and sadness at a funeral, all for the sake of the audience. People even fool themselves in the sense that faking a smile can make them ever so slightly happier or faking a frown a wee bit sadder (a phenomenon known as the *facial feedback hypothesis*).

Third, people have goals, and emotional expressions may be mobilized in their service. Goals may be conscious (e.g., "I will pretend to feel guilty so he won't punish me") or unconscious (as when blushing serves as an automatic apology and appeasement gesture). People usually want others to know about their actual emotional state for a reason, or they want to hide that state for a different reason. Likewise, people receiving an emotional message have their own goals: to help, to resist, to avoid being taken advantage of, or to ignore the others' feelings because they are too upsetting. Thus, emotionally charged interactions may have the subtext of negotiating whose emotions are more important.

Because human beings are fundamentally social creatures, the tendency to adjust emotional expressions to others runs deep. People laugh at funny videos more when they know their friends are in another room laughing too. People tend to wince when they see someone hurt her finger, especially if she sees them, too. Some scholars argue that others are so much a part of the human psyche that humans are never truly alone and are thoroughly in the habit of taking others into account. At a cultural level, emotions and their expressions are deeply socialized so that people follow the patterns and practices of their forebears and contemporaries at a level that is completely taken for granted.

Connecting Emotionally

The question of how accurately emotion is communicated between people has proven to be difficult to answer. Certain carefully chosen facial and vocal expressions of basic emotions can be identified at levels greater than chance, but moving the issue of emotional accuracy into the real world of combinations of cues, blended emotions, subtle

expressions, complex social settings, potential deception, and audience adaptation presents humbling challenges for researchers. It seems, however, that identifying another's emotion with a word or two is not how people relate emotionally; instead, they try to understand how others are feeling in richer ways that may include trying to understand the cause(s), subjective experiences, and implications of the others' emotions. People also "catch" each others' emotions via emotional contagion, such as with contagious laughter or when irritation spreads through a family at the end of the day. People also feel what others feel by imagining their situations, which is called *empathy*. Empathizing with others tends to promote helping, though not always.

Skills, Intelligence, and Competence

Emotional competence or intelligence is widely recognized as a critical factor in friendships, romantic relationships, and work relationships. Simply expressing one's emotions (venting) may require more skill than meets the eye. Evidence suggests that nonverbal expressions of anger such as hitting a pillow do more harm than good by reinforcing destructive behaviors. On the other hand, talking or writing about feelings in appropriate ways may produce personal insight, relief from stress, and stronger social connections. Above all, the receiver of the message must be considered, raising a host of complex concerns for reputation, confidentiality, social norms, possibilities for shared insights, listeners' distress, and effects on intimacy. Thus, there is no simple answer to the simple question of whether expressing emotions is healthy or not.

Even more challenging are the skills involved in regulating or managing the emotions of oneself and others. One way to feel better may be to vent, but more constructive ways may be to rethink the situation, plan constructive action, or seek help and advice. In all relationships, partners must weigh and negotiate both partners' feelings while pursuing joint goals, managing conflict, or simply trying to help one another, and all that requires skillful emotional communication. Skills related to providing sensitive social support, managing stress and conflict, dealing with transgressions,

maintaining feelings of closeness, and handling personal emotional difficulties, such as depression, that affect relationships have received extensive study.

Social, Cultural, and Historical Contexts

Emotional communication does not occur in a social, cultural, or historical vacuum. Social rules and norms, taken-for-granted communication practices, and cultural and historical guidelines and ideals all influence and are influenced by emotional communication. Certainly appropriate emotional communication depends on whether one is a child or adult, male or female, powerful or powerless, Balinese or Inuit, or living in the days of the Vikings or the Internet. Getting it wrong may make people seem to be incompetent, crazy, people who "don't know their place," or people who "aren't one of us." Getting it right can enforce cultural values, increase interpersonal solidarity, and uphold power structures. For these reasons, it is important to recognize that emotional communication is much more than simply letting others know how you feel.

EMOTIONAL CONTAGION

In recent years, scholars from a variety of disciplines—anthropology, neuroscience, biology, social psychology, sociology, life-span psychology, and history—have proposed that the process of primitive emotional contagion is critically important in understanding cognition, emotion, and behavior. Primitive emotional contagion appears to be a basic building block of human interaction—assisting in “mind-reading,” allowing people to understand and to share the feelings of others, as well as coordinate and synchronize their activities with others.

Most social psychologists agree that emotional “packages” comprise many components—including conscious awareness; facial, vocal, and postural expression; neurophysiological and autonomic nervous system activity; and instrumental behaviors. Different portions of the brain process the various aspects of emotion. Yet—because the brain integrates the emotional information it receives—each of the emotional components acts on and is acted upon by the others.

In the 1990s, Elaine Hatfield and her colleagues defined primitive *emotional contagion* as “the tendency to automatically mimic and synchronize facial expressions, vocalizations, postures, and movements with those of another person’s and, consequently, to converge emotionally.”

The Emotional Contagion Scale (ECS) is designed to assess people’s susceptibility to catching joy and happiness, love, fear and anxiety, anger, and sadness and depression, as well as emotions in general. The ECS has been translated into a variety of languages—including Finnish, German, Greek, Telugu, Japanese, Portuguese, and Swedish.

Personality theorists who have administered this scale in a variety of cultures have discovered that there are cultural, personality, gender, and situational differences in people’s susceptibility to emotional contagion. People are most likely to catch others’ emotions in two kinds of relationships—those involving love or power. We are particularly susceptible to contagion in the company of those we like and love and those who possess power over us.

According to scholars, contagion may occur in a number of ways. At first, scholars took it for

granted that conscious reasoning, analysis, and imagination accounted for the ubiquitous phenomenon. Recently, however, social psychologists have concluded that primitive emotional contagion is a far more subtle, automatic, and ubiquitous process than once thought. This entry describes the mechanisms of emotional contagion and the implications of existing research.

Mechanisms of Emotional Contagion

There is considerable evidence that the process of emotional contagion occurs in three stages: Mimicry → Feedback → Contagion.

1. *Mimicry*: People appear to automatically mimic or synchronize their facial expressions, vocal productions, postures, and movements with those around them. Daters, for example, might catch themselves mimicking their date’s silly giggle or angry, sarcastic demeanor. People are capable of doing this with startling rapidity, automatically mimicking or synchronizing a number of emotional characteristics in a single instant.
2. *Feedback*: People tend to feel pale reflections of emotions consistent with the facial, vocal, and postural expressions they adopt. The link between facial, vocal, and postural expression appears to be quite specific. When people mimic expressions of fear, anger, sadness, or disgust, they tend to feel a pale reflection not just of any unpleasant emotion but with those specific expressions (e.g., those who mimic a sad expression feel sadness, not anger or shame). For example, college students assigned to share a room with a deeply troubled roommate may start feeling increasingly anxious and depressed themselves during the semester.
3. *Contagion*: As a consequence, people tend, from moment-to-moment, to “catch” others’ emotions.

Recently, discoveries in neuroscience have provided some insight into why people so readily “catch” the emotions of others and why it is so easy for people to empathize with others’ cognitions, emotions, and behaviors. For example, neuroscientists contend that certain neurons (*canonical neurons*) provide a direct link between perception and action. Other types of neurons (*mirror neurons*) fire when a certain type of action is performed and when primates observe another animal

performing the same kind of action. Scientists propose that such brain structures account for emotional contagion and empathy in primates, including humans.

Other neuroscientists have argued that imagining, observing, or in any way preparing to perform an action excites the same motor programs used to execute that same action. A great deal of recent research demonstrates that, in humans, several brain regions (specifically the pre-motor and parietal cortices) are activated both during action generation and during the observation of others' actions. These scientists argue that this mirror system allows people to plan their own actions and to understand the actions of others.

In the 1950s, primatologists conducted a great deal of research indicating that animals do seem to catch others' emotions. They found, for example, that monkeys often transmit their fears to their peers. The faces, voices, and postures of frightened monkeys serve as warnings; they signal potential trouble. Monkeys catch the fear of others and thus—in kind of a “monkey see, monkey do” fashion—are primed to make appropriate avoidance responses. Ethologists argue that the imitation of emotional expression constitutes a phylogenetically ancient and basic form of intraspecies communication. Such contagion also appears in many other vertebrate species, including mice.

In conclusion, scholars from a variety of disciplines provide compelling evidence that people do catch one another's emotions. They appear to catch the emotions in all societies and in a wide variety of individual and group settings.

Implications of Existing Research

In the Emotional Contagion paradigm, scholars confront a paradox. People seem to be capable of mimicking others' facial, vocal, and postural expressions with stunning rapidity. As a consequence, they are able to feel themselves into those other emotional lives to a surprising extent. And yet, puzzlingly, most people seem oblivious to the importance of mimicry or synchrony in social encounters. They seem unaware of how swiftly and how completely they are able to track the expressive behaviors and emotions of others.

What are some implications of the preceding research for the nature of contagion? The research

on emotional contagion underscores the fact that men and women use multiple means to gain information about others' emotional states. Conscious analytic skills can certainly help people figure out what makes people “tick.” But if people pay careful attention to the emotions they experience in the company of others, they may well gain an extra edge into “feeling themselves” into the emotional states of others. Both of these means provide valuable information. In fact, evidence indicates that both what people think and what they feel may provide valuable, but different, information about others. In one study, for example, social psychologists found that people's conscious assessments of what others “must be” feeling were heavily influenced by what the others said. People's own emotions, however, were more influenced by the others' nonverbal clues about what they were really feeling.

We see then that primitive emotional contagion may provide a solid foundation for helping friends, lovers, and family members communicate their feelings to one another, convey their solidarity, and behave in a smooth and coordinated way.

EMOTIONAL INTELLIGENCE

The term *emotional intelligence* (EI) was introduced to the scholarly literature in 1990 in two

journal articles written by Peter Salovey and John D. Mayer. These researchers proposed a model to explain individual differences in people's ability to use emotion-related information to enhance thinking and problem solving. In 1997, Mayer and Salovey revised their model and published a formal theory that defined EI as a set of four mental abilities pertaining to the perception, use, understanding, and regulation of emotion.

EI was popularized in 1995 by Daniel Goleman in his bestselling book on the topic. Since then, a variety of "mixed" conceptualizations of the construct have emerged. Whereas Mayer and Salovey's ability model includes only mental skills that directly involve the interaction of affect and cognition to facilitate complex problem solving, mixed models incorporate personality traits such as motivation and optimism in addition to the types of emotion-related skills found in the ability model. Research shows that self-report inventories based on mixed model conceptions of EI lack discriminant validity from established measures of personality.

This entry focuses solely on the ability model of EI, the performance measures that have emerged from this perspective, and a review of research on the interpersonal correlates of EI. Emotions are at the heart of human interaction and relationships; thus, it is no surprise that relationship researchers are taking the construct of EI seriously.

The Mayer and Salovey Model of Emotional Intelligence

Mayer and Salovey's model of EI consists of four branches or abilities (i.e., the perception, use, understanding, and regulation of emotion), each of which corresponds to a distinct set of skills. Before emotions can be understood or regulated, they must be interpreted accurately. Thus, the first and most fundamental branch of EI, *perceiving emotion*, includes the abilities to identify, distinguish, and express emotions. Emotions are revealed in artwork, vocal intonations, facial expressions, gestures, and one's own physiological sensations, as well as in numerous other channels. Each of these modes of expression demands keen perception to process and understand them well.

Researchers have long known that emotions alter cognitive processes. The second branch of EI,

using emotion, involves the practical application of this knowledge: the ability to generate emotions in oneself and in others, resulting in different cognitive states. People tend to be more creative, optimistic, and big-picture-oriented when they are happy, for example, and more pessimistic and detail-oriented when they are sad or angry.

The third branch of EI, *understanding emotion*, refers to both crystallized knowledge of emotions as well as to the ability to predict how one's emotional state will evolve as a situation changes. The former subset of understanding emotion includes one's emotion vocabulary, that is, knowledge of emotion-related words, as well as awareness of the adaptive value of emotions. Emotion researchers have posited, for example, that anger helps individuals focus on an obstacle impeding their progress to a goal and energizes them so that they can overcome that obstacle, whereas fear encourages them to flee when met with a situation that seems too dangerous to confront. Another part of understanding emotion, predicting future emotional states based on individuals' current emotions and the surrounding events, demands knowledge of how emotions progress and give way to other emotions. If a situation that elicits irritation continues to stymie an individual, for example, eventually that irritation will turn into anger.

The fourth branch, *managing emotion*, involves the ability to regulate one's own and others' emotions. A distinction must be made between mere emotion suppression and effective emotion regulation. Effective emotion management does not include stifling potentially uncomfortable emotions such as anger. Emotions focus attention on the event that caused the emotion, and suppressing emotions precludes access to the information that can be gained by paying attention to them. Managing emotion instead involves remaining open to these cues and using them to guide attention, for example, to problems that need to be addressed. Effective emotion management occurs by recognizing and, when possible, addressing the problem causing the emotion, rather than by ignoring the emotion itself. Managing emotion is the most advanced of the four branches of EI in that one must draw on the first three branches to manage emotion properly. For example, a person would be unlikely to help a friend manage his sadness if he failed to perceive the sadness or did not

understand what it would take for the sadness to progress to a different emotion. Effective emotion management requires observation of the initial emotion, understanding of what actions might result in the desired change in emotion, implementation of the action, and judgment of the effectiveness of the action.

Measuring Emotional Intelligence

Mayer and Salovey's model of EI is measured with the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT), a performance test. The MSCEIT assesses the four-branch model of EI with 141 items that are divided among eight tasks (two for each branch). Unlike self-report measures, each task on the MSCEIT requires the test-taker to answer questions in which some responses to each question are objectively more accurate than others.

Perceiving Emotion is measured by asking test-takers to identify the emotions expressed in photographs of people's faces (Faces) as well as the feelings suggested by artistic drawings and landscapes (Pictures). *Using Emotion* is measured by two tasks that assess the ability to describe emotional sensations and their parallels to other sensory modalities (Sensations), and identify feelings that might enhance or hinder the successful performance of various cognitive and behavioral tasks (Facilitation). *Understanding Emotion* is measured by two tasks that pertain to a person's ability to analyze blended or multifaceted emotions (Blends) and to understand how emotional reactions transform over time (Changes). Finally, *Managing Emotion* has two subtests that assess participants' knowledge of the best strategies for managing both their own emotional experiences (Emotion Management) and the emotions of others (Social Management).

On the MSCEIT, the quality of the test-takers' responses is judged by comparing their responses with those given by experts in the field of emotion research (21 members of the International Society for Research on Emotions) or to responses given by a consensus sample of approximately 5,000 individuals. Research shows that these two scoring methods correlate highly and that correlations with various outcomes replicate across the two scoring methods. The MSCEIT also demonstrates

predictive and cross-cultural validity (in its translated versions, which include German, French, Italian, and Spanish). EI scores as measured with the MSCEIT are positively associated with a range of outcomes including academic achievement, life satisfaction, and relationship quality. The scores also negatively predict such outcomes as deviant behaviors (e.g., engaging in physical fights, gambling, and vandalizing) and alcohol and illegal substance use. Finally, the tasks in the MSCEIT yield results that are distinct among the people who take the test, suggesting that the four branches represent separate, though related, abilities.

Emotional Intelligence and Human Relationships

Emotions affect all aspects of human relationships. Emotional states influence whether individuals reach out to their loved ones or push them away, what messages they express when they communicate, and how they go about nurturing their relationships (or not). Each branch of EI as well as the construct as a whole is linked to strong social bonds.

Numerous studies have found associations between people's ability to perceive emotion and the quality of their interpersonal relationships. Students who are better able to recognize emotions in photographs of faces and recordings of voices have been found to report greater relationship well-being. Similarly, husbands in satisfied marriages have been found to be better able to identify the meaning of their wives' vocal tone than have their counterparts in unhappy marriages. No association was found between wives' ability to recognize the meaning of their husbands' vocal tone. Some scientists argue that this gender difference occurred because women tend to have higher EI than men, and that the majority of the wives participating in the study passed some minimum threshold of emotion-related ability that many of their husbands did not.

The second branch of EI, using emotion to facilitate thought, is particularly relevant to human relationships in the form of empathy. The term *empathy* can be applied to a host of distinct definitions ranging from feelings of sympathy and pity to cognitively taking on the perspective of another

person. In this context, however, EI researchers consider empathy to mean the ability to generate in oneself the emotions that another person feels. This “emotional synchrony” and the mimicry that often accompanies it, such as similar posture, vocal tone, and facial expression, are associated with greater fondness between empathic perceivers and the people with whom they empathize. The link between empathy and affinity does not seem to be unidirectional; people are more likely to mimic those whom they like than those whom they do not, and controlled experiments have found that people quickly become more fond of others who mimic their emotional expressions.

A large lexicon of emotion words is necessary to communicate one’s feelings accurately to others. People who are able to express their emotions effectively tend to be more satisfied with their relationships. Even in relationships where both parties are skilled at identifying emotions, frank conversations about emotions are necessary to ensure that each partner in the relationship understands how the other feels and what caused those emotions. This is especially important in situations where one person is distraught or angry over some element of the relationship (as is inevitable in close relationships); talking about the emotions and the causes behind them can inform the other person so that the partners can together address the issue.

After discussing an emotional event or a problem in the relationship, acting to address the issue requires effective emotion management. Constructive responses such as speaking calmly and listening tend to result in greater relationship satisfaction, whereas destructive responses that dismiss and belittle the other person generally lead to dissatisfaction. As discussed earlier, effective emotion management includes remaining open to emotions, even those that may be uncomfortable. The alternative, suppressing emotion, is often linked to greater dissatisfaction in relationships. Forgiveness is also related to emotion management. Not surprisingly, the desire to avoid or seek revenge on someone who has wronged an individual is associated with decreased future relationship quality, whereas expressions of benevolence toward the wrongdoer are associated with greater closeness in the future. Overcoming the urge for revenge or creating distance from the person who committed the wrong requires good emotion management, which often

involves discussing the issue with the offender and coming to an understanding about what is acceptable and desirable to both individuals.

EI researchers at the Health, Emotion, and Behavior Laboratory at Yale University assert that EI allows for easier navigation through the emotionally intense situations that characterize interpersonal relationships. Indeed, several studies suggest that EI, as measured by the MSCEIT, is positively associated with relationship quality and satisfaction among friends, classmates, and romantic partners.

The mechanisms that link EI and relationship quality are still uncertain. The most probable explanation, though, is that each branch of EI contributes to relationship quality in different ways. Perceiving emotion, for example, allows individuals to recognize friends’ and loved ones’ distress, whereas using emotion to facilitate empathy may help them understand the others’ point of view. Understanding emotion may then encourage an open discussion about the emotions, and managing emotions may help them confront the source of the distress. Relationship quality is best achieved with the full range of emotion-related abilities in EI.

EMOTIONALLY FOCUSED COUPLE THERAPY

Emotionally Focused Couple Therapy (EFT), first formulated in the early 1980s, is now accepted as a validated intervention for relationship distress and as appropriate for diverse kinds of distressed couples, including those dealing with traumatic stress, depression, illness, and problems with forgiveness and the renewal of trust. This short-term therapy (8 to 20 sessions) aims to help couples see and reshape the negative cycles of interaction, such as the demand-withdraw pattern, in which one partner's requests for changes are met by withdrawal rather than open consideration, that undermine their emotional bond and to clarify emotional signals so that needs and fears can be addressed. This leads to new positive cycles where each partner can reach for, connect with, and comfort the other. The relationship then becomes a safe haven and secure base, a source of strength and resilience for both partners. The EFT therapist will help partners see the cycle that creates their distress and gradually express and respond to each other's emotions in new ways.

EFT is used with couples from many different cultures and educational levels. Research finds that more than 85 percent of couples that receive EFT are able to significantly improve their relationships. Results appear to be stable over time with little evidence of relapse after treatment. A deeper engagement with key emotions and the open, coherent expression of these emotions and associated needs to the other partner predict positive outcomes.

Research on the nature of relationship distress supports the focus of EFT interventions, namely specific negative emotions, anger, fear, sadness, and shame, and negative self-perpetuating patterns

of interaction such as escalating anger in conflict discussions. For example, John Gottman has found that fear and anger on partner's faces and patterns where one partner criticizes while the other distances predict divorce. On a positive note, EFT attempts to help partners order and clarify their emotional signals and tune into each other's deeper emotions and needs. Ted Huston and colleagues have demonstrated that this emotional responsiveness predicts the quality of newlywed relationships 5 years into their marriage. This entry describes Attachment Theory and EFT in action.

Attachment Theory: A Map for Lovers

EFT is the first couple therapy to be based on a clear, systematic, and well-researched theory of adult love, namely Attachment Theory, as formulated by British psychiatrist John Bowlby. This theory, first applied to adult relationships in the late 1980s, views emotional openness and responsiveness as the bases of a secure attachment bond. Attachment Theory states that the most basic need for human beings is a safe emotional connection with one or two irreplaceable others who will be responsive to our needs when we are vulnerable. The most basic questions in a marriage are then, "Can I count on you? Will you respond to me when I call? Will you put me first and value me and our connection?" Such connections are humankind's most basic survival mechanism and the main and most healthy way of dealing with vulnerability and anxiety. Emotional isolation is traumatizing and disorienting for human beings. Positive love relationships offer a safe haven in times of stress or uncertainty and a secure base from which to explore the world. The more connected we are then to loved ones, the more confident, autonomous, and open to the world we can be. Being able to turn to others for comfort and support and to hold positive images of others in our minds is a source of strength and resilience. In secure relationships, partners can tune into and organize their emotions, accept their need for love and connection, and give clear signals about this need to loved ones. They can accept comfort when it is offered and then, strengthened and supported, cope with the world's challenges. The EFT therapist works with a couple so that, at the end of

therapy, each person can do this and can also respond to the needs of the other.

When partners cannot connect emotionally, an automatic sense of panic, loss, and separation distress is activated. If this panic can be balanced by a sense of trust and connection, it appears as a protest and reaching for the loved one that, at least some of the time, results in reconnection. Margaret says, "When life comes for me, or when I suddenly feel distant from my husband and doubt our relationship, I can get mad or just assert myself and tell him, 'Hey, where are you? I need some cuddles and reassurance here.' And he responds." If the panic becomes overwhelming and there is a sense of helplessness and hopelessness, partners become more and more anxious and angry and try to force their loved one to respond. This can become a habitual emotional response and way of communicating with the loved one. If a partner has learned to block out this panic and deny any need for others, perhaps because past close relationships have been hurtful, the usual response is to become emotionally numb and shut down, thereby shutting out the other person. These negative responses to disconnection can become automatic—a personal style that shapes a person's expectations and so his or her relationships. These styles, which start out as ways of dealing with lack of connection, can then become self-defeating and self-perpetuating. Most often in distressed relationships as a more anxious and controlling partner demands and criticizes, the other avoids more and becomes less responsive. As this partner avoids more and more, the anxious partner's sense of insecurity spirals, and the couple becomes stuck in a demand-withdraw pattern that leaves them both isolated. In EFT, this anxiety and avoidance can be addressed so that more secure bonding moments are created.

Attachment Theory tells us what our basic needs are in love relationships and how our ways of communicating our emotions either help us achieve loving connection or send our relationships spiraling into negative patterns. It helps us make sense of the key moments that shape our relationships. This theory also outlines how love relationships affect us, body and soul. Isolation from loved ones seems to flood us with stress hormones and undermine our immune system, but close connection is calming and allows us to deal with stress and adapt to new situations. Patterns of interaction

also help define our sense of self, how acceptable we believe we are, and our sense of trust in other people. The Israeli psychologist Mario Mikulincer has shown that when we feel more connected to others, we have a clearer, more defined and more positive sense of self. A map and a language for adult love allow a couple to acknowledge emotional needs and move into more open and responsive dialogue. Research indicates that this kind of change is necessary for couples to make satisfying, significant, and lasting changes to their bond.

EFT in Action

The EFT approach to improving relationships focuses on how partners tune into and express their emotions to each other and how they then create a dance—patterns of connection or disconnection. This moment-to-moment dance shapes each person's emotions, and emotional signals then shape the dance. There are three stages in EFT: the de-escalation of negative cycles, the creation of positive cycles of loving responsiveness, the consolidation of positive change.

In the first stage of EFT, the therapist holds a mirror to the negative patterns that have taken over a couple's relationship. The goal is to help the couple see their dance as it evolves and as it traps them both in isolation. Once a couple can see these patterns ("I push and you shut me out. So then I feel more alone and push more. We get stuck here.") and understand their impact, they can empathize with each other as victims of the cycle, rather than blaming and demonizing each other. The attachment framework also helps them begin to articulate and express inner emotions rather than becoming caught in reactive rage or minimizing and dismissing feelings and needs. At the end of Stage 1, a couple can contain conflict behaviors and can come together as a team to restore their relationship. They are better friends, but they are still not close or securely connected.

In Stage 2 of EFT, partners are guided into a deeper awareness of attachment emotions and more explicit sharing of their attachment needs and fears. The therapist creates safety and acts as a consultant to the process of emotional exploration and communication. In general, more anxiously attached partners uncover fears of being abandoned and deserted. They speak of being

alone and unable to count on their partner. More avoidant withdrawn partners usually speak of feeling inadequate, a helpless sense of being unable to please their partner, and a fear of rejection. The goal of the therapist is to help more withdrawn partners fully engage with their own emotions and their loved one and so assert their needs and to help more aggressive critical partners to recognize their fears and ask in a positive way for their attachment needs to be met. In this hypothetical example, Paul might gradually be able to share with his wife Claire the following:

“I have shut you out. I didn’t understand how hard that was for you. I just saw you as demanding and angry. I didn’t see your sadness.

“I am overwhelmed by your anger. When I see that look on your face, I want to run and hide. I freeze up. Everything feels hopeless, like I have already lost you. I feel so small, like I can never make it with you.

“I feel lonely too and I do want to be close, but I need you to step out of the judge’s chair and give me a chance here. I want you to stop monitoring me, waiting for me to make a mistake. I want some sense that we are struggling together and that I am your man, even if I don’t always know how to connect here.”

The EFT therapist will help Claire tune into her husband’s message, defusing any residual hostility and confusion and will also help Claire to reciprocate and open up to her husband. Claire might then offer the following responses:

“I do get critical, anything to get a response from you. I am so scared that you will just turn away. I have never felt so alone as in this relationship. I get scared that I don’t really matter to you at all.

“It’s very hard to show you my fear rather than getting mad. If I ask you and you do not reassure me, I will be even more hurt. I guess I really need that reassurance, that I am precious to you and you need me too. It is very hard to ask for this.

“Some part of me is even ashamed of asking. I was taught that you had to stand alone and be independent. But I want our closeness back. I need to know I matter to you and that you won’t turn away.”

This kind of dialogue creates a new positive cycle of disclosure and safe emotional connection that is deeply rewarding and provides an antidote to negative moments of disconnection. At times, it is also necessary to add a specific focus on healing emotional injuries that, if unresolved, block the creation of trust. The healing of moments of abandonment and betrayal, such as affairs or lack of responsiveness at key moments of need such as in illness or traumatic loss, is also part of Stage 2 of EFT. A recent study suggests that this EFT forgiveness process is effective.

Once couples can connect in the manner described, they can move into Stage 3, Consolidation, where they can formulate new stories of how their problems evolved and how they were able to repair the connection between them. They can also create attachment rituals, perhaps special ways of soothing each other or connecting after time apart, and can easily solve pragmatic problems that are no longer infused with attachment fears and meanings. All through this process, the therapist helps clarify each partner’s emotions and responses and gradually supports couples to interact in more positive and caring ways. Emotion is the music of the couple’s dance; new emotions create a new dance.

EMOTION IN RELATIONSHIPS

Emotions play a large role in relationships and are central to personal and relational health. Emotion signals whether a social situation is pleasant or unpleasant and helps organize personal actions to respond to the social situation. Emotion also communicates information to others about one's current state (positive or negative), informs others about one's relational orientation (e.g., dominance, affiliation) and intentions (e.g., "I want to hug you") toward them, and communicates need of a *socially coordinated response* (e.g., "I need support to manage this situation").

The term *emotion* is often used interchangeably with "feelings"; however, scientists understand emotions as more than just the subjective experience of "feelings." Emotions involve conscious and nonconscious processes that together form the experience of an emotion. To understand emotions, scientists examine self-reports about how people experience emotion and assess neurological and physiological arousal, facial displays, vocalizations (e.g., speech), and gestures in circumstances in which people experience emotion. This entry discusses how scientists define and measure markers of emotion and briefly reviews research to understand the role of emotion in relationships.

Definition

Emotion is a product of a core, "hardwired" system that evaluates the environment for situations that are relevant to personal motives and goals and that may potentially affect the well-being and survival of the person. This coordinated response system calls the mind and body into action. Changes include shifts in perception and attention; physiological functioning, both autonomic (e.g., heart rate, skin conductance) and endocrine (e.g., hormone production); gross motor behaviors (e.g., muscle tone, posture); and expressive behaviors (e.g., facial and vocal

displays, gestures), many of which occur without awareness. However, many conscious processes are also associated with emotion, including awareness of feelings as well as motivated, intentional actions (e.g., disclosing emotions, seeking physical closeness to another). Notably, the emotion system also has an elaborate structure dedicated to emotion regulation, affecting the way social information is appraised as well as how responses to feelings are managed.

Although the emotion system itself is located within the person, emotion by its nature is a process about the social environment. That is, the emotion system is stimulated by changes in environmental circumstances (which is almost invariably about how people are relating to others) and signals the valence (positive or negative) of the experienced relational changes. Further, one's internal states are communicated to others through facial expressions, vocalizations, and gestures, thereby signaling whether one is likely to draw closer to or create greater distance from others. Emotion thereby may dictate personal behavior as well as socially regulate others. Thus, although the architecture of the emotion system may be personal, the function is tethered to the social world, including relationships.

Elicitation and Measurement

To study the experience and expression of emotions, scientists have used many different methods. Some methods involve tasks that are typically performed by the person alone, such as guided imagery, memory recall, or stimulus exposure, whereas other techniques engage participants in actual interactions with others to evoke an emotional response or understand how an emotional response is received by another.

When scientists show stimuli to evoke particular emotions or affective states, these usually take the form of film clips or slides. Film clips typically show social interactions (e.g., a comedian telling jokes to audience) or graphic scenes (e.g., an amputation procedure) and slide sets show pictures of positive and negative objects or scenes (e.g., flowers, a snake eating a frog). Emotions are also elicited unconsciously using a technique called backward masking, which consists of a brief presentation of a target stimulus (e.g., pictures of

spiders, puppies) immediately followed by a masking stimulus (same pictures only cut and reorganized to form new stimuli). This technique allows both stimuli to be perceived yet only the masked one to be consciously recognized, thus allowing researchers to measure the extent to which people show different thresholds for recognition and reactivity to emotionally evocative stimuli.

Studies in which participants interact with others are designed to richly capture the complexities of emotional exchange in the natural world. The “others” can be confederates (people who actually work for the researcher and act in particular ways to elicit reactions in participants) or they may be actual relationship partners who are also participants in the study. When using confederates, social situations are constructed and tightly controlled in the laboratory by the experimenter and participants are led to believe that interactions with confederates are real. Interactions between pairs of actual friends, romantic partners, parents and children, or other dyads may either be naturalistic observations or observations during a semi-structured protocol by which participants are asked to interact (e.g., spouses are asked to engage in conversations about positive topics, such things they enjoy doing together, relationship conflicts, or “neutral” topics such as events from the day).

Tools to assess emotion vary with the kind of information researchers want to capture. Self-reports can take the form of single-item or multiple-item questionnaires (e.g., how much sadness did you experience when watching the film?) or affect dials (e.g., rating intensity of happiness experienced during segments of the film). Surveys can be administered at one point in time, as when the experimenter is assessing participants’ reactions to a specific film clip or feelings about an interaction with another person, but they can also be administered repeatedly, as done in diary studies in which feelings during the day or feelings about interactions with others can be tracked over time. When studies involve dyads such as husband and wife, reports from each partner are gathered to understand each person’s emotional experience, as well as to understand the match (or mismatch) between partner’s feelings and interpretations of and reactions to the other.

When study participants are observed, researchers often use elaborate coding systems—for example,

the Facial Affect Coding System (FACS) or Specific Affect Coding System (SPAFF)—to characterize the quality, timing, and intensity of participants’ emotional experiences and/or expressions. The FACS analyzes facial expressions into the smallest possible facial movements (called action units), specifying combinations of head and eye positions and movements, gross motor behaviors, and other actions that indicate the occurrence of emotion. The SPAFF system analyzes communications in dyads (e.g., couples, peers, parents and children), including facial displays from the FACS as well as information about vocal tone, verbal content, and body movements. When this information is combined, different affective sets are created (e.g., affection [positive], defensiveness [negative]) that capture how each partner is emotionally oriented toward the other. In other laboratories, detailed accounts of vocal acoustics (e.g., amplitude, pitch, tone, speech rate) and language properties are also assessed from observational data.

Heart rate, skin conductance, electroencephalographic activity (EEG; scalp recorded brain electrical activity), and electromyography (EMG; eyeblink startle magnitude measuring muscle tension/contraction) are markers typically used to measure the physiology of emotion. Notably, using these markers, researchers examine whether people are aroused by a particular stimulus, as well as the quality of their arousal. For example, sympathetic neural and adrenal medullary axis (SAM) and hypothalamic-pituitary-adrenocortical axis (HPA) patterns can indicate differences in how a person is oriented toward circumstances in his or her social environment (e.g., challenging versus threatening).

Using neuroimaging (particularly functional Magnetic Resonance Imagery, or fMRI), emotionally evocative stimuli can be presented and even some forms of social interaction can occur (e.g., holding the hand of a romantic partner) while the brain is continuously scanned. These scans allow researchers to look at the momentary unfolding of brain responses to emotional stimuli—including information on which areas of the brain are stimulated, when emotional content is detected and how quickly areas react, and how long areas take to become activated, remain activated, and recover after the stimulus is removed. With these techniques, researchers are also able to construct a model about reciprocity (e.g., feedback loops)

between different brain areas during emotionally evocative situations.

Finally, psychoneuroimmunology (PNI) focuses on how emotion influences cardiovascular, endocrine, immune, and neurosensory functioning, as well as health and disease over the long term. In laboratory studies, researchers create social situations (e.g., evaluation by judges while giving a speech discussing conflict with a spouse) to understand baseline, anticipatory, acute, and recovery response phases to these social stressors. These markers are also assessed repeatedly over time to understand differences between people in activation and habituation of responses to social stress.

Research

The literature on emotion is vast. Although there is no agreed upon number of discrete emotions, basic emotions (e.g., fear, anger, disgust, sadness, joy, interest) have been shown to be similarly experienced and expressed across diverse cultures. Research also suggests that emotional experience and expression are innate. That is, infants experience emotions and show emotional expressions long before they ever “learn” them from other people. The functions of the emotion system are elaborated and extended significantly over early development, and the social environment, including caregivers and peers, plays a large role in optimal development.

Early in infancy and childhood, emotion serves as the primary medium of communication, first as a signaling system to others indicating the child’s physical and psychological discomfort (e.g., hunger, distress when left alone). This signaling system then becomes motivated by goals of attention and comfort seeking and is used to move others to action for the child’s benefit (e.g., infant smiles when the parent helps the child reach a toy). Children use others’ emotional displays as social references to determine their own behaviors (e.g., when mom smiles and provides verbal encouragement, the child is more likely to initiate behaviors), and they also learn about their own and others’ emotional states and behaviors by witnessing and participating in social interactions with others.

Emotion also plays an important role in the construction and organization of the self-concept,

including how the self is regarded in relation to others as well as how one reacts and behaves socially. The social context continues throughout the life span to be a principal source of determining *what* emotions are displayed to *whom* and *when*. Notably, partner’s responses are influenced in part by the child’s temperament (overall disposition, ease of emotional activation, intensity of emotional response, with the nature of the emotional exchange potentially enhancing or undermining emotional development).

Importantly, the emotion system serves a significant social communication and coordination function not only in infancy and childhood, but across the life span. Emotion calls relevant others into action to guide social goals or processes (e.g., mating). For example, emotions such as passionate and companionate love catalyze motivation to approach others and create greater social bonds, and may further provide incentives or reinforce others’ social behavior. Indeed, organized facial and body cues that indicate interest in affiliation signal the other to begin the mating repertoire and reinforce their approach. Intimacy also develops through transactions of self-disclosure of *emotionally* relevant information and partner responsiveness (conveying acceptance, validation, and care for the discloser). Indeed, greater mutuality in such social exchanges is predictive of greater intimacy over time, with intimacy serving as a protective factor for personal well-being. When there are threats to the social bond (e.g., feeling hurt by one’s partner), emotion can also catalyze protective or reparative behaviors within the relationship, and thereby alter (at least temporarily) closeness to relational partners. Research has shown that when partners are less responsive to each other’s needs, the more defensive and less open they are to each other and the less they feel satisfied and vital in their relationship.

Emotional expression further organizes others around common emotional processing (e.g., grieving) such that the load of the emotional experience is shared. For example, in securely attached relationships, when a person perceives threats from the environment, caregivers or other close relational partners are recruited (e.g., through crying, proximity seeking, verbal requests) to help manage emotions. This social coordination of experience and expression of emotion has important implications for well-being. Some neurobiological

evidence even points to the emotion system as essentially *coregulated*, or in other words, at its basic neural level designed to maximize personal energy expenditures by relying on others to reduce risk or harm to one's own well-being and share in the load of managing emotions.

How does the emotion system coordinate all of these functions? First, from neuroscience, it is known that the amygdala, hippocampus, orbital frontal cortex, anterior cingulate cortex, prefrontal cortex, and hypothalamus are all implicated in emotional experience. Research shows pre-attentive processing occurs more rapidly for threat-relevant cues compared with positive or neutral stimuli. Research has also shown that people process faces quite rapidly, with negative facial expressions processed more quickly than are positive facial expressions. Further, some research suggests that the social context matters, such that the personal relevance of facial cues (e.g., mom's angry face vs. a stranger's angry face) can even activate the same brain areas differently. The processing advantage of negative information speaks to an important preparedness to act efficiently in adapting to the social environment when it threatens well-being. Notably, however, beyond this common pattern, individual differences in affective style have also been found, reflecting systematic differences in how people respond emotionally (that is, the relative positivity or negativity with which they react to similar life circumstances).

Cognitively, affect is used as information to shape attitudes and judgments, make decisions, and form and influence memory. People attempt to assess emotional consequences of any given situation in terms of maximizing positive and minimizing negative emotions, and to guide decisions based on their expectations of these emotions. Generally speaking, evidence suggests that positive and negative affect have different consequences for social information processing, such that positive affect is associated with more flexible and less effortful processing, and requires less information to respond, whereas negative affect requires greater attention and vigilance, as well as effortful and systematic processing.

Finally, relational stressors have been shown to be associated with autonomic activation and hormonal activity. Both high-impact stressor events (e.g., divorce) as well as low-grade repeated "hits"

(e.g., ongoing conflict) show links to immune functioning. Overall, research shows that social stressors may increase vulnerability to infectious illness and stress-related alterations in immune functioning can potentially have additional implications for recovery and long-term health.

Adults' emotional system may also change as they age. Age-related differences have been shown (a) in the ways in which situations are appraised (both as a function of learning and as the meaning of the environmental events change in valence, intensity, and relevance to personal goals and motives) and (b) in the extent to which people exert control over or employ others in the regulation of emotions. For example, physiological reactivity has been shown to diminish with age, and attentional biases in older adults favor avoidance of negative information. Older adults also tend to structure their environments to minimize negative experiences (e.g., reduce conflicts) and associated emotions and instead try to amplify opportunities for positive events and emotions. Thus, change in the emotion system may be both a product of maturational change as well as self-selection of social situations.

Current Directions

Several important theoretical and methodological advances are shaping the field's understanding of emotion. First, scientists have begun to study the importance of positive emotion for relational and personal health more rigorously. Second, there is some debate about whether experience and expression of all emotions is healthy. For example, much debate has centered on the extent to which an emotion (e.g., anger) is situationally appropriate and constructive to experience and express. However, given the utility of negative emotion to signal that something is awry in the social environment and to mobilize personal and social resources to address the situation, even anger has a vital adaptive function. Thus, science is now examining how severity, frequency, and persistence of negative emotions affects relational connectedness and thereby imposes costs on well-being. Finally, research examines how the frequency and persistence of positive and negative emotion affects psychological, physical, and relational health in the short term and cumulatively over the long term.

Important methodological trends in studies on emotion include a focus on being more ecologically valid (e.g., incorporating personally relevant pictures, vignettes, or tapes) to richly capture the nature of emotion as it occurs in a person's everyday world. Also, much research has focused on how partners affect each other's emotions and how psychological and physical well-being is affected in the short and long term. New methods, such as virtual reality, have emerged that elicit emotional responses by immersing participants in an evocative situation (e.g., walking across a very high bridge) or interaction with avatars (computer-generated others or real others controlling the avatar's responses). Finally, researchers are assessing the convergence of varied emotion markers in a variety of social circumstances to understand how dissociations between emotional markers (e.g., significant physiological arousal but no facial display) have important implications for personal and relational health.

EMOTION REGULATION, DEVELOPMENTAL INFLUENCES

If you have ever seen a 2-year-old at a party or in a toy store trying to get a particular toy that he or she wants, you might have seen frustration escalate into

a temper tantrum. The child begins to cry or even scream, reaches repeatedly toward the toy, and clutches his or her small fists. You might have smiled or been annoyed, but you also understood that the child had simply not yet learned to regulate his or her emotions. The goal of this entry is to describe the developmental process in emotion regulation. The entry begins with brief definitions of emotion experience and emotion regulation before addressing the developmental influences on emotion regulation.

Emotion Experience

Emotion experience begins when the body feels some type of positive or negative arousal. For a few basic emotions (e.g., fear, anger, sadness, joy, disgust), the body recognizes the emotional state quickly and activates programmed response tendencies, such as certain facial expressions (e.g., frowns or smiles) and certain physical reactions (e.g., rapid heart rate or muscle tension). However, scientists have learned that in many circumstances the link between a state of arousal and recognition of emotional experience is influenced by more conscious levels of thought. For example, most people feel fear immediately if a large dog suddenly jumps toward them with a growl. However, when called to speak in front of a group that same type of arousal might be experienced as anxiety, stage fright, or embarrassment. In addition, because some emotions are complex blends of more basic emotions, they require conscious processing and even reprocessing. Emotions such as romantic love, pride, resentment, disappointment, guilt, jealousy, envy, embarrassment, and shame are understood by reference to the circumstances that elicited the arousal. For example, guilt and shame are experienced after social rules or norms are violated, and embarrassment is experienced after losing face in public by tripping or spilling a soft drink. Sometimes emotions are experienced after a more intense emotion has passed. For example, a person may feel strong anger and respond inappropriately, then later feel lingering guilt for having said something hurtful to another person.

Emotion Regulation

Importantly, experiencing an emotion is only one half of the emotion equation. The other half is

how that experience, its intensity, and its expression are controlled. Scholars call this process *emotion regulation*. More specifically, emotion regulation involves modifications of one's emotions or emotional expressions to accomplish individual goals and adapt to the social environment. At the same time, a person is interpreting the nature of the emotional arousal, he or she is also evaluating or enacting coping strategies.

Emotion regulation decisions are based on appraisals of the social situation and individual and relational goals. People sometimes let themselves feel strong sadness and express it fully in the presence of a close friend to receive emotional support. However, in public, people often subdue the intensity of their sadness and its expression to appear strong and in control. Likewise, in a romantic relationship, partners may express jealousy to let a partner understand that the relationship is valued and that a threat has been perceived. By contrast, if a friend wins an award that one feels more qualified to win, feelings of envy are often subdued and instead congratulations are offered.

Although researchers have studied emotion regulation from several perspectives, Paul Ekman and Wallace Friesen have made one of the most important contributions to our understanding of expression regulation. These authors describe five display rules that govern the expression or suppression of emotional experience. They include *simulation* (showing emotions that we do not actually feel), *inhibition* (not displaying an emotion that we do feel), *intensification* (displaying emotions more intensely than we actually experience them), *minimization* (displaying emotions less intensely than we actually experience them), and *masking* (displaying an emotion that is different from the one that we are actually experiencing). Although adults typically follow these rules with little conscious effort, children must learn how and when to use them. Masking is particularly challenging for young children because it requires both simulation and inhibition at the same time. Imagine a young child who opens a birthday gift with great excitement only to find something that he or she does not want. The knowledge and skill necessary to hide the disappointment and instead display happiness are sophisticated accomplishments that are learned over time.

Developmental Influences

Emotion regulation abilities begin to develop in infancy and expand rapidly during the first 2 years. Among the first emotions that infants experience are the primary emotions of pleasure/joy, anger, sadness, and fear. From birth, infants cry when distressed and smile when contented, often spontaneously in their sleep. However, during the first year, infants learn to use these unfocused displays as meaningful signals to interact with others in the social environment. For example, by about 6 months, infants begin to smile when interacting with their mothers and other family members. In a sense, they have learned that emotional expression is a communication act that can be used symbolically. When a mother smiles as she lifts her baby from the crib, the baby experiences a positive feeling and smiles back; mother continues the caretaking activity and the smile. The interaction reinforces for the infant a reciprocal link between mother's smile, his or her positive feelings, his or her smile, and the continued positive outcomes. Both baby and mother are rewarded. In much the same way, by about 6 months, infants have learned to modify their crying in different ways to signal hunger or discomfort versus anger or frustration when a desired goal is blocked. In short, babies learn early that certain displays help them meet their goals and satisfy their needs.

By 18 months, even more remarkable emotional competence emerges. Toddlers begin to exhibit what scholars call "self-conscious emotions," emotions associated with awareness of a "self" that is judged by others (e.g., guilt, shame, and embarrassment). For example, in one experiment, researchers asked mothers to place rouge on the nose of their toddlers and place them in front of a mirror. Toddlers younger than 18 months seemed to have no emotional response. However, by about 18 months, the toddlers became upset when looking at themselves in the mirror. Although they didn't know the word, they were experiencing embarrassment. By 18 months, children are also beginning to develop the ability to feel empathy for the emotional states of others. This level of development is evident when a 2-year-old offers a hug to another child who is crying, as if to say, "I feel better when mom hugs me so I will hug you."

Emotional development becomes increasingly sophisticated throughout childhood. By 6 years of

age, children understand that emotion experience can be complex. They realize that they can feel two emotions at the same time (e.g., sad and frightened). By about 10 years of age, children even experience contradictory emotions such as being happy about doing well but simultaneously feeling sad that a friend did poorly. Emotion expression also becomes increasingly sophisticated. Researchers have found that children in elementary school report that they would more likely avoid expressing sadness, fear, and physical pain to their classmates than to their parents. These children may be attending more carefully to display rules in front of their peers because they assume that their classmates are more likely than their parents to make negative attributions about their personality.

In sum, the development of emotion regulation knowledge and skills is a complex process that begins in infancy and continues throughout childhood and adolescence, even into puberty. Unfortunately, many parents and other caregivers are not aware of the influences they exert in this process. In general, these influences are analyzed by researchers as *indirect* and *direct* influences.

Indirect influences on the development of emotion regulation arise from two mechanisms that operate when children are in the presence of family members or other care providers. The first is *emotional contagion* and the second is *modeling*. These two processes work together in teaching children, indirectly, how to regulate their emotions. Based on the work of Elaine Hatfield and her colleagues, researchers have begun to study emotional contagion, or the extent to which the emotions experienced by one person are vicariously experienced by others who are in the person's presence. Although empathy is usually a constructive response to the emotions of others, when strong negative emotions are experienced, it can be problematic. Thus, when children experience the positive emotions of their parents, the result is a healthy and satisfying home environment. However, when they experience the negative emotions of their parents, the result is a tense or distressing home environment. Even when parents attempt to suppress their negative emotions, they may be experienced by children who react to leakage cues in a parent's voice, body posture, or facial expressions.

Likewise, when parents have emotionally charged conflict in front of their children, some

children will feel threatened and withdraw, but others will actually experience the anger projected by their parents. The children may suppress these feelings (often leading to depression) or they may model their parents' behavior and openly express their own anger at home or in other situations. Young boys who witness negative parental conflict have difficulty controlling their anger during adolescence and tend to be aggressive toward their dating partners in high school.

Direct influences on children's emotion regulation development are exerted by parents through their communication (or lack of communication) with their children about emotions. John Gottman and his colleague interviewed parents to learn how they deal with their children's negative emotions and then observed them interacting with their children in a laboratory setting. This research offers two important insights into the parents' role in emotion regulation. First, when parents do "emotional coaching" by accepting and respecting a child's negative feelings but also talking with the child about what the emotion means and alternative ways to express it, the child learns how to regulate his or her emotions in other contexts. As a result, the child has good self-esteem, is socially and academically competent at school, and appropriately expresses emotion in varied social contexts.

Second, when parents respond in less thoughtful ways to a child's emotions, the child will be less emotionally and socially competent. These other response styles include (a) accepting the child's emotion but not talking with him or her about how to understand or express it, (b) ignoring the child's emotion as though it were unimportant, and (c) punishing the child for expressing the emotion but not discussing alternative options for expression. Because emotionally dysfunctional or detached parents are less likely to do emotional coaching, their children also tend to be less competent in regulating their emotions as they mature.

The foundation for successful emotion regulation provided by some parents gives their children an advantage during the turbulent years of adolescence. As children enter adolescence, they face new challenges that test their emotion regulation competence. First, as part of their growing sense of autonomy, they explore their behavioral independence from their parents, as well as their emotional independence. This opens adolescents to relatively

stronger influence from their peers than they may have experienced previously. Adolescents with well-developed emotion regulation strategies are better able to understand their emotional experience, manage their anger during conflict with friends, and anticipate the implications of their emotion displays (e.g., prosocial or self-protective).

Second, during the maturation process, adolescents experience hormonal, physical, psychological, and social changes that contribute to greater frequency and intensity of emotion experience. Emotion regulation skills help adolescents cope with these transitions. For example, researchers found that adolescents (Grades 7 and 10) who did not have good emotion regulation skills reported more intense emotions and rapid mood swings over a one-week period and were more likely to display problem behaviors (e.g., lying, swearing, stealing, and destroying property) compared with adolescents with better emotion regulation skills.

In sum, emotion regulation begins to develop during the early months of life and remains a critical aspect of social functioning from infancy through adolescence and into adulthood.

EMOTION REGULATION IN RELATIONSHIPS

Broadly defined, *emotion regulation* refers to the psychological and interpersonal processes through which individuals consciously or unconsciously alter their emotional experiences or expressions. Emotion regulation *in relationships* refers to these processes as they occur during interactions with relationship partners, such as friends, family members, or spouses. Emotion regulation can occur within any relationship, but it has received the most attention within *close* relationships because such relationships have particularly strong influences on our immediate and long-term emotional experiences. Processes of emotion regulation in relationships have received increased scientific attention in recent years because they are thought to explain the well-documented influence of social relationships on mental and physical health. Specifically, it is thought that well-functioning relationships foster physical and mental benefits by regularly heightening positive emotionality and dampening negative emotionality. Poorly functioning relationships, in contrast, are thought to hamper physical and mental health by heightening negative emotionality and dampening positive emotionality. This entry discusses different forms of emotion regulation in relationships, their implications for relationship functioning and overall well-being, the different strategies that have been used to study emotion regulation in relationships, and directions for future research.

Basic Mechanisms

Emotion regulation in relationships can occur through conscious and intentional processes or through unconscious and automatic processes. An example of conscious and intentional emotion regulation is social support. When people feel depressed, stressed, or frightened, social partners can help regulate these negative feelings by providing comfort and support, communicating empathy, providing an alternative perspective on problems, or simply distracting a person from his or her troubles. In some cases, people may benefit from these forms of social support without even

realizing it. For example, research shows that individuals whose romantic partners have offered them support subsequently experience greater positive and less negative emotion, even when they report no awareness of their partners' support attempts. Moreover, other studies have suggested that even in the absence of specifically supportive interactions, the simple presence of a close relationship partner can amplify positive emotions and alleviate distress, even lowering physiological reactivity to psychological stress. These findings are consistent with the extensive body of research indicating that individuals with close supportive relationships live happier, healthier lives, potentially as a direct result of such sustained stress regulating effects.

In other cases, emotion regulation occurs through automatic processes that are regular features of routine social interactions. For example, individuals tend to unconsciously "catch" and mimic the emotions of social partners, especially when these social partners are close and important. Some researchers have suggested that this "emotion contagion" or "emotional convergence" is an adaptive feature of most relationships that promotes general social functioning by allowing individuals to understand and share the experiences of others. For example, *empathic accuracy*, or the ability to detect and respond to another person's emotional state, can promote relationship satisfaction and success when the emotions in question are positive and nonthreatening.

Negative Emotions

The same processes of empathic accuracy, emotion contagion, emotional convergence, and even social support can prove *maladaptive* when the emotions in question are negative (such as anger or sadness), or when they pose a threat to the relationship (such as jealousy or contempt). Studies have found that one of the potentially destructive characteristics of poorly functioning relationships is a tendency for negative emotions to spread from one partner to the other and to rapidly escalate through social interaction. This is particularly likely to occur during conflict, and can make it increasingly difficult for both partners to respond sensitively to each other and to negotiate solutions

to their disagreements. There are also negative physiological consequences to patterns of shared and escalating negative emotions within close relationships. Extreme negative emotions and hostility during marital conflict, for example, have been found to trigger heightened cardiovascular reactivity and heightened production of stress hormones. Over many years, these physiological patterns increase both partners' health risks.

One such pattern that has been widely investigated within heterosexual couples is called "female demand/male withdraw." In this pattern, the wife makes a series of escalating demands of her partner, who then attempts to regulate his own distress by emotionally and behaviorally withdrawing. This exacerbates the female partner's negative emotions, prompting her to intensify her demands and—paradoxically—triggering greater withdrawal by the partner. Such patterns are detrimental and maladaptive on a basic interpersonal level, because they fail to adequately resolve the conflict in question, but can also be conceptualized as fundamental failures of interpersonal emotion regulation. Instead of helping to attenuate their distress, partners are actually *escalating* each other's negative emotions. Studies have found that couples that regularly reciprocate each other's negative emotions, instead of interrupting or alleviating negative emotions, have higher rates of dissolution over time. In contrast, couples who counterbalance routine negative emotional experiences with frequent *positive* emotional interchanges have greater relationship satisfaction and success. An example of such counterbalancing might be the interjection of humor into an otherwise difficult discussion, which can provide a brief respite from negative emotionality, de-escalate tension, and provide a moment of shared pleasure between partners. Much of this research on these dynamics has focused on marital conflict, but similar processes have also been observed between parents and children. For example, parent-adolescent dyads that tend to reciprocate each other's negative affect during conflict discussions end up falling into detrimental "cascades" of ever-increasing negative emotion.

Positive Emotions

The majority of research on emotion regulation within relationships has focused on negative

emotions, either by examining the ability of social partners to alleviate distress or by examining processes through which partners inadvertently escalate each other's distress during conflict. In recent years, greater attention has turned to the regulation (and specifically, the amplification) of *positive* emotions and relationships. Studies have increasingly demonstrated that well-functioning relationships are characterized by the absence of unregulated negative affect and by specific *presence and amplification* of positive affect. In particular, the most beneficial and satisfying interpersonal interactions appear to be those in which positive affect is expressed, validated, and mirrored by a relationship partner. For example, the simple process of sharing good news with another individual magnifies the event's positive emotional impact, a phenomenon called *capitalization*. These processes of mutual positive emotion regulation reinforce and prolong one's positive feelings and indicate the partner's engagement and responsiveness, enhancing the rewarding nature of the interaction itself and of the relationship as a whole.

Studies have found that positive emotions can counteract the negative interpersonal, psychological, and physiological consequences of negative emotions, and can contribute to effective coping. For example, positive emotions have been theorized to broaden individuals' thought-action repertoires and build their intrapsychic and interpersonal resources, partly through facilitating creative and flexible cognition and adaptive problem solving. Hence, researchers interested in emotion regulation processes within close relationships have begun to increasingly investigate how couples can strategically use shared—and amplified—positive emotional experiences to help one another regulate negative emotions, and to prevent negative emotional interactions (such as conflicts) from escalating to a dysfunctional level.

Individual Differences

Not all individuals go about regulating their emotions in the same way, and this is particularly true with regard to emotion regulation within relationships. The most widely studied form of variability in interpersonal emotion regulation is *attachment style*. Attachment styles are stable expectations

regarding the availability and responsiveness of romantic partners that are thought to develop from early interactions with caregivers. In recent years, researchers have come to conceptualize these styles as also providing an organizing framework for affective experience, expression, and regulation.

Specifically, it is theorized that individuals with *secure* attachment styles are confident of the availability of social partners to assist them in times of distress and tend to appraise external demands as manageable challenges rather than as unmanageable threats. In contrast, individuals with *anxious* or *avoidant* attachment styles adopt more negative, threat-based appraisals of environmental demands and adopt ineffective emotion regulation strategies. For example, individuals with high attachment anxiety tend to be hypervigilant to cues of threat, increasing their day-to-day negative emotional reactivity. Once they experience negative emotions, they tend to focus on and ruminate about these feelings, which has the effect of heightening and magnifying them. Finally, they show patterns of spreading emotional reactivity such that one negative thought or memory triggers many others, and such that distress experienced in one area of life spills over to other areas. Anxious individuals' tendency to experience heightened negative and reduced positive affect also extends to their romantic relationships. Those high in attachment anxiety tend to interpret their partners' negative or even ambiguous behaviors in more threatening ways and their positive behaviors in less positive ways. This negative attributional bias also appears to account in part for anxious persons' lower reports of relationship satisfaction.

Attachment avoidance, on the other hand, is conceptualized as involving *minimization* and suppression of emotional experience. These individuals tend to report distancing themselves from others during times of distress, and typically show few outward signs of distress. Avoidant individuals also show low levels of support-seeking behaviors, especially in stressful circumstances, and they report low levels of subjective distress even when physiological markers of distress are evident. Thus, both attachment anxiety and avoidance are consistently associated with deficits in the regulation of both negative and positive affect, and both patterns are associated with the inability to derive

emotion-regulating benefits from contact with attachment figure as well as lower empathy and lower responsiveness to partners' emotional needs.

Research has also detected stable individual differences in capacities for *physiological* regulation of emotional states, which has implications for interpersonal processes of emotion regulation. For example, research on both infants and adults has found that individuals with robust parasympathetic nervous system functioning (typically described as *vagal tone*) show more rapid and flexible cardiovascular responses to environmental challenges, which is thought to provide an important substrate for efficient and effective regulation of negative emotions. Other studies have focused on individual differences in stress-related activity in the hypothalamic-pituitary-adrenocortical (HPA) axis of the endocrine system (typically assessed through the release of *cortisol*, a stress hormone). As with the parasympathetic nervous system, flexible and efficient reactivity and recovery in the HPA axis is thought to provide an index of flexible and effective emotion regulation across the life course. The integration of cognitive and behavioral perspectives on individual differences in emotion regulation with *physiological* perspectives is a promising direction for new research in this area.

Research Strategies

The many different manifestations of emotion regulation within relationships call for different research strategies. Researchers have used a variety of creative methods to capture these processes. Most of these methods rely—at least to some extent—on individuals' self-reports of their positive and negative emotional states. There is considerable variation, however, in the periods over which such reports are made. For example, some studies might ask individuals to describe how they “generally” feel when interacting with different social partners, under different circumstances. Other studies have attempted to capture more specific linkages between social interactions and emotional experiences by asking participants to keep brief diaries (sometimes once a day, sometimes multiple times within the same day) of social experiences and their immediate affective consequences. In some cases, for example, individuals

might be signaled by an electronic pager to describe their most recent interpersonal interaction and the resulting emotional state. In other cases, assessments of physiological reactivity (such as blood pressure, which can be measured with ambulatory monitors that individuals wear throughout the day and even overnight) are timed to correspond with such reports to provide an additional measure of interpersonally triggered emotional reactivity. These designs are particularly adept at capturing “emotion regulation in action,” as it unfolds during routine (and not-so-routine) social exchanges.

Other widely used methods attempt to capture this process by bringing individuals into controlled laboratory settings, exposing them to emotion-eliciting events, and examining how their interpersonal interactions modulate their affective states. For example, couples might watch an emotion-eliciting film together and be observed during their conversation afterward. Alternatively, one member of a dyad might undergo a stressful performance task, and the other member might be instructed to provide comfort and support in whatever manner he or she deems appropriate. The benefit of these approaches is experimental control: Researchers can precisely calibrate the emotion-eliciting stimuli, permitting direct comparisons between the different strategies that dyads might employ to mutually regulate their responses to these experiences, and the effectiveness of these strategies. In other cases, researchers attempt to “re-create” naturalistic emotional experiences within a controlled laboratory setting. For example, many studies of romantic couples ask partners to discuss a topic of frequent and heated conflict with each other, to trigger the types of emotion regulation strategies that they might typically use at home together.

A key advantage of such laboratory-based studies is the capacity to collect observational and physiological data on dyads' emotional reactivity. Hence, in addition to testing whether a spouse's supportive behavior elicits *reports* of greater positive emotion, researchers can examine whether such reports are borne out by an individual's facial expressions, posture, and physiological responses. Such multifaceted assessments provide a more complete portrait of individuals' emotional experiences and help determine whether certain forms of

emotion regulation within relationships have stronger effects on one dimension of emotion (for example, self-reported happiness) than others (cardiovascular reactivity).

Future Directions

New theoretical and empirical approaches to emotion regulation have been emerging within various research traditions, ranging from experimental social psychology to affective neuroscience. Researchers are increasingly pursuing interdisciplinary approaches involving the simultaneous collection of data across multiple levels of emotional activation, such as brain activity (assessed through functional Magnetic Resonance Imaging, or fMRI), hormonal changes, and autonomic nervous system reactivity. Researchers are also increasingly investigating whether individual differences in capacities and strategies for emotion regulation in relationships correspond to physiological predispositions for different types of regulation. For example, many studies have begun to investigate whether individuals who have consistently high levels of stress hormones in response to day-to-day challenges, or consistently high blood pressure reactivity, end up pursuing consistent forms of emotion regulation within the context of their close relationships.

Another important emerging trend in research on emotion regulation within relationships involves the collection of detailed, “real-time” diary reports of emotional experience and regulation from *both* interaction partners simultaneously. Methods for analyzing such dyadic data have also become more sophisticated, making it possible to analyze data sequentially to determine how relationship partners’ emotional responses to one another unfold, build, escalate, and de-escalate during an interaction. This is particularly important for identifying whether there are “optimal” forms of coregulation in relationships. Some researchers, for example, have suggested that most adaptive “outcome” of effective emotion regulation within a relationship might *not* be a high and stable level of positive emotion, but rather a flexible give-and-take between partners involving loose coupling of oscillations in positive and negative mood, and efficient transitions between moments of self-regulation

(i.e., “I manage my *own* negative emotions to avoid burdening you”) and moments of interactive regulation (i.e., “I take advantage of opportunities to boost *your* positive affect through enthusiastic responses to your positive emotional displays and expressions”). From this perspective, the goal is *not* a perfect matching between partners’ states, but an intermediate degree of emotional coordination and interdependency.

In summary, research on emotion regulation in relationships is an active, thriving area of inquiry that has much to offer designed to human relationships. Researchers are increasingly coming to understand that processes of mutual cognitive and emotional linkage between members of a dyad may be a fundamental component of all human relationships and may play a key role in determining whether these relationships are experienced as rewarding or stressful, growth promoting or constraining, and how they influence relationship partners’ long-term mental and physical health.

EMPATHIC ACCURACY AND INACCURACY

Empathic accuracy refers to the degree to which one person can accurately infer the specific content of another person's thoughts and feelings. During the past two decades, psychologist William Ickes and his colleagues have extensively studied this phenomenon in the context of close relationships. The results of their research suggest that relationship partners are often motivated to “manage” their empathic accuracy—usually seeking to know, but occasionally seeking to avoid knowing, what their partner is thinking or feeling.

The standard method for measuring empathic accuracy in relationship partners is the unstructured dyadic interaction paradigm. In this paradigm, the partners are left alone together in a

waiting-room situation for several minutes, while the experimenter is presumably completing a necessary errand. During this brief observation period, the partners' spontaneous interaction is covertly audio- and videotaped. At the conclusion of this interaction, the partners are seated in separate cubicles, where they individually view a copy of the videotaped interaction and stop the tape at each point where they remember experiencing a particular thought or feeling. The partners also write down the specific content of these thoughts and feelings, noting the times when they occurred. Then they view the tape again, this time for the purpose of writing down their inferences about the content of their partner's reported thoughts and feelings at each of the partner's “tape stops.” People who can accurately infer the specific content of their partner's thoughts and feelings, based on the comparative judgments of trained raters, are considered to be high in their empathic accuracy. This entry describes several aspects of research into empathetic accuracy and inaccuracy.

Individual Differences in Empathic Accuracy

Although people with severe autism seem unable to infer the content of other people's thoughts and feelings, this ability is evident in all normally developing individuals by the time they reach adolescence. The overall level of empathic accuracy varies from one individual to another, however, and these individual differences (typically in the range of 0 to 60 percent accuracy) have important effects on people's social lives and their personal adjustment. For example, researchers have found that adolescents with low empathic accuracy experience greater peer victimization and report a range of personal adjustment problems that are less likely to afflict their more empathically accurate counterparts.

Despite the popular stereotype of “women's intuition,” which presumes that women are, on average, more empathically accurate than men, reviews of the relevant research findings suggest that the average woman in our society does not have more empathic ability than the average man. On the other hand, evidence indicates that women will display more motivation to accurately “read” other people's thoughts and feelings in situations

where they are reminded that women are supposed to excel in this regard.

Temporal Changes in Empathic Accuracy Within Close Relationships

Are friends more accurate than strangers in their ability to infer the specific content of each other's thoughts and feelings? The answer, not surprisingly, is yes. Friends do, indeed, infer each other's thoughts and feelings more accurately than strangers do, but friends' performance is typically in the 30–40 percent range—far short of 100 percent accuracy. The available research suggests that friends achieve their greater accuracy by making use of relevant background knowledge they have acquired about each other's interests, values, feelings, and life experiences through previous discussions.

Although the empathic accuracy of same-sex friends appears to develop rapidly during the first few months of their acquaintance and then to increase only slightly after that, the empathic accuracy of married couples seems to peak within 2 years after the marriage and then to decline somewhat. This decline may occur because the husband and wife are now preoccupied with different roles and concerns that make it more difficult for them to “stay on the same page” and share a common cognitive focus. They may also have acquired a false sense of confidence that they already understand each other so well that they no longer have to pay close attention to what the other person is saying and doing. Research findings indicate that attentiveness is important no matter how well the partners think they know each other.

Empathic Accuracy and Inaccuracy

The association between empathic accuracy and relationship satisfaction was initially assumed to be a simple one: The more accurately relationship partners can “read” each other's thoughts and feelings, the more satisfied they should be with their relationship. Although several studies (for example, a study of newlywed couples conducted by Shelley Kilpatrick, Caryl Rusbult, and Victor Bissonnette) have revealed the expected positive relationship between these two variables, other studies have not. Indeed, some studies have

revealed a negative relationship between empathic accuracy and relationship satisfaction, particularly in situations where partners are dealing with high-conflict issues that they find difficult to resolve. The link between empathic accuracy and relationship satisfaction has proved to be more complicated than early researchers assumed.

To account for these more complex relationships, William Ickes and Jeffry Simpson proposed a theoretical model of how empathic accuracy is “managed” in relationships. According to this model, greater empathic accuracy usually helps improve relationships in situations where the partners' actual thoughts and feelings are benign and nonthreatening. On the other hand, greater empathic accuracy can actually harm relationships in “danger zone” situations in which the partner's actual thoughts and feelings are potentially threatening to the relationship (for example, accurate inferences about a partner's dislike of one's faults or a partner's sexual attraction to others will often damage the relationship more than less accurate inferences will). Consistent with these propositions, the results of a study of married couples revealed that greater accuracy in inferring a partner's nonthreatening thoughts and feelings was associated with feeling closer to the partner, whereas greater accuracy in inferring a partner's relationship-threatening thoughts and feelings was associated with feeling less close to the partner.

When perceivers find themselves in a “danger zone” situation in which it is likely that their partner is harboring relationship-threatening thoughts and feelings, they may be motivated to be empathically inaccurate, rather than accurate, to avoid having to confront and deal with the partner's potentially hurtful and destabilizing thoughts and feelings. In these instances, motivated inaccuracy may actually help to keep the relationship stable and intact in the face of a short-term threat. Motivated inaccuracy is likely only a short-term solution that will be increasingly less effective over time. Individuals who repeatedly “turn a blind eye” and ignore their partner's potentially relationship-damaging behavior may successfully avoid an unpleasant confrontation now, but set themselves up for an even more unpleasant and consequential confrontation later on.

Several studies have shown that individuals vary in the strength of their motive to learn about their

relationship partners' potentially threatening thoughts and feelings. At one extreme are men and women who have an avoidant attachment style that leads them to minimize any potential negative contact with their partners. These individuals often decline to attempt to infer their partner's relationship-threatening thoughts and feelings, even when instructed to do so. At the other extreme are women who have an anxious-ambivalent attachment style that leads them to become highly vigilant at the first sign of a potential threat to their relationship. These anxious-ambivalent women tend to be quite accurate in inferring their male partners' relationship-threatening thoughts and feelings, even though they pay a price for this knowledge in their subsequent feelings of jealousy and perceived threat. (For reasons that aren't yet clear, anxious-ambivalent men are less likely to do this.)

Similar individual differences have been identified on a measure of the motive to acquire relationship-threatening information (often referred to by its acronym—MARTI). People with high MARTI scores have "suspicious minds" and usually want to know their partners' relationship-threatening thoughts and feelings, even if it might hurt the relationship. In contrast, people with low MARTI scores are less suspicious of their partners and are less likely to "go out of their way to look for trouble." People with moderate MARTI scores probably seek to find a balance between being overly suspicious and not being sufficiently sensitive to potential problems in their relationships.

Empathic Inaccuracy of Maritally Aggressive Men

An interesting example of empathic inaccuracy is provided by maritally aggressive men. These men, when compared with their less aggressive counterparts, are biased to believe that women harbor critical and rejecting thoughts and feelings about their male partners. The strength of this bias is related to the inaccuracy of the men's empathic inferences and to the degree of wife-directed aggression they report.

Maritally aggressive men appear to sustain this biased way of thinking by employing two independent strategies: (1) "tuning out" when their female partner is talking (so that they don't have to learn

what she is actually thinking and feeling) and (2) reacting to her attempts to express herself with feelings of contempt rather than sympathy. Both strategies keep aggressive/abusive men from learning how their wives actually feel, thereby enabling them to sustain the biased perception that their wives are harboring critical and rejecting feelings about them. They can then, quite unfairly, use these perceived critical and rejecting feelings as a justification for the aggression they direct toward their wives.

Interestingly, the empathic accuracy of maritally violent men is significantly lower for their own wives than for female strangers. This finding contributes to the growing evidence that maritally violent men have an "empathic deficit" that is expressly directed toward their own spouse's thoughts and feelings as a way of maintaining control within the relationship. These men appear to be motivated not to want to know their wives' actual thoughts and feelings, because this knowledge might require the men to understand their wives better and perhaps even sympathize with them. By making themselves relatively insensitive to their wives' actual thoughts and feelings, maritally violent men can perpetuate the biased attributions that enable them to continue to abuse their female partners.

Clinical Implications of Research on Empathic Accuracy and Inaccuracy

The research on empathic accuracy and inaccuracy suggests some pitfalls that psychotherapists should avoid when treating partners in distressed relationships. These pitfalls include (a) the hazards of forcing partners to infer each other's relationship-threatening thoughts and feelings more accurately before the therapy has prepared them to do so; (b) the instability of relationships involving partners who have an anxious attachment orientation, a pervasive bias to "see" criticism and rejection where none is intended, or a strong motive to acquire relationship-threatening information; and (c) misinterpreting the reluctance of avoidantly attached partners to confront the danger-zone issues in their relationship.

To avoid the first pitfall, the therapist must accept the fact that many relationships are predicated on the partners' routine *avoidance* of

each other's relationship-threatening thoughts and feelings. For many couples, the implicit agreement to follow the policy of "don't ask, don't tell" may be the primary reason why their relationship has worked as well as it has. If the therapist fails to appreciate this fact, more harm than good can be accomplished when the partners are pressed to confront their most relationship-threatening issues before they feel that they have made sufficient progress in their therapy to do so.

To avoid the second pitfall, the therapist must realize that some people are predisposed to "look for trouble" in their intimate relationships, and that their readiness to confront relationship-threatening issues may be part of the problem rather than part of the solution. People in this category can include suspicious partners who have a strong motive to acquire relationship-threatening information; aggressive-abusive men who have a pervasive bias to "see" criticism and rejection in their wives' thoughts and feelings; and women with an anxious attachment orientation, who act as if they are compelled to know their husbands' relationship-threatening thoughts and feelings. Although different interventions may be required in each case, the therapist should learn to recognize these predispositions to "look for trouble" and make them a focus of the therapy.

To avoid the third pitfall, the therapist must realize that some people are so motivated to *avoid* confronting the danger-zone issues in their relationships that they will appear not to care about a relationship that they actually value greatly. Perceiving such clients as stubborn, uncooperative, or uncaring can blind the therapist to the reality of what is often an anxious and withdrawn person who needs continued reassurance rather than blunt confrontation.

EMPATHY

In the broadest sense, *empathy* refers to the reactions that one person has to the observed experiences of another. Beyond this general definition, however, psychologists have conceived of this phenomenon in a number of more specific ways. Disagreements over the "proper" definition of empathy have been a long-running feature of this field. However, underlying all of these definitional approaches is one core assumption: that empathy in some way involves the transformation of the observed experiences of another person into a response within the self. Thus, empathy is a psychological phenomenon that at least temporarily *unites* the separate social entities of self and other. Because of this, empathy can affect relationships in a variety of ways. This entry reviews the differing definitions of empathy that have dominated this literature. It also discusses the implications of empathy for relationships.

The most fundamental definitional distinction has been between viewing empathy as an essentially cognitive phenomenon or as a fundamentally emotional one. The cognitive view sees empathy as an intellectual process in which one person attempts to understand the internal state of another person—thoughts, feelings, or intentions. The term *perspective taking* (or *role taking*) is often used to describe this process. Some versions of this

approach consider perspective taking to be the *attempt* to infer others' internal states; other versions equate perspective taking only with *successful* attempts that result in an accurate inference.

Such inferences could be made in several ways. An observer might start with the assumption that a target's reaction in a given situation is probably similar to what the observer's would be in a comparable situation—the observer might then “project” his or her own likely responses to the target. Alternatively, an observer might use other sources of information to make such inferences. The target's words, facial expressions, and body language can all provide information about the target's emotional state. Prior knowledge about the target might also be used to infer a current internal state, and knowledge about groups to which the target belongs can be used to determine the target's likely attitudes or values.

The emotional view of empathy, in contrast, defines *empathy* as some kind of affective reaction in the observer that results from observing the target. However, no clear consensus exists regarding the precise nature of this emotional response. Some have argued that empathy consists of the observer and target experiencing the same or similar emotions—a phenomenon sometimes known as emotional contagion. Others have argued that empathy occurs when the observer comes to have feelings of sympathy and compassion for the target. Other affective states that have been nominated include empathic anger (when a target has been mistreated), empathic joy (when a target has experienced success), and even “contrast empathy” in which the target's misfortune produces enjoyment in the observer. However, the most common contemporary view is probably that emotional empathy is an affective response to another's experience that is congruent with, but not necessarily identical to, that other's own experience.

In recent years, there has been growing acceptance of the view that empathy can best be considered a multidimensional phenomenon that encompasses both cognitive and affective elements. One such view holds that it is useful to distinguish between empathy-related processes (such as motor mimicry, associative learning, and perspective taking) and empathy-related outcomes, both cognitive (e.g., accurate perceptions) and affective (e.g., feelings of sympathy). Moreover, these cognitive and emotional responses

in turn contribute to interpersonal outcomes such as aggression and helping behavior.

One consequence of this approach is the growing use of multidimensional measurement techniques. For example, one widely used measure of dispositional empathy (the Interpersonal Reactivity Index) assesses four different facets of empathy. Two of these are clearly affective: empathic concern (the tendency to feel sympathy for those in distress) and personal distress (the tendency to feel personal discomfort when faced with distressed others). Another is clearly cognitive in nature: perspective taking (the tendency to imagine the point of view of other people). The final scale is more difficult to characterize: the fantasy scale measures the level of identification with characters in books, movies, and plays.

To reiterate, in a variety of ways empathy creates cognitive and emotional connections between people, and as a result often influences social behavior. Although it is not an exhaustive list, empathy can shape interactions through at least six broad avenues.

Empathic Accuracy

As previously noted, one school of thought regarding empathy has placed primary emphasis on attempts to determine the internal states of other people. Thus, *empathic accuracy* refers to our ability to accurately infer others' internal states without regard to whether we experience any affective response while doing so. This view of empathy has a long history, and empirical attempts to study empathic accuracy have been made for more than 50 years. However, methodological difficulties plagued the early research, and only relatively recently has significant progress been made. Much of this more recent work has been conducted or inspired by William Ickes.

It now appears that humans are capable of accurately inferring the moment-by-moment internal states of other people, both thoughts and feelings. For example, if Harry and Susan are talking, Harry may be able to infer something about Susan's current mood even if she does not announce it. He may do so by using facial expressions and vocal cues, or by using his prior knowledge about Susan to interpret what she says.

Although we can be accurate even with strangers, the best performance typically occurs when we attempt to “read the minds” of our friends and romantic partners. The shared knowledge and experience that friends possess is a considerable aid in the inference process. In addition, it appears that empathic accuracy is more likely when we are motivated to be accurate. That is, if there is a real value to us for making correct inferences, then we try harder and perform better.

How important is such empathic accuracy? Interestingly, the relationship between empathic accuracy and overall relationship satisfaction is not clear. Sometimes greater accuracy is associated with happier relationships, but not always. In fact, if there is reason to believe that an accurate inference about one’s partner might be painful or threatening—perhaps if Harry correctly perceives how attractive Susan finds another man—then intimate couples sometimes display less accuracy. Thus, although empathic accuracy would seem to offer some obvious relationship benefits, especially in improved communication, it also appears that the value of accuracy may have some clear limits.

Emotional Synchrony

Another way that empathy influences social relationships is by creating an *emotional synchrony* between people—that is, a match between the observer and target in the quality or intensity of their emotional states. This synchrony in turn has positive effects on the quality of the interaction and the relationship. Recent theory and research have tended to focus on one particular mechanism by which these parallel emotions are created: the tendency of observers to mimic the target’s facial expressions, vocal intonations, posture, and movements. Considerable evidence suggests that observers often engage in a veritable symphony of unconscious mimicry during social interaction, imitating the facial expressions, bodily movements, posture, speech rate, and vocal intensity of their interaction partners. Moreover, evidence indicates that mimicry in each of these channels can contribute to the creation of parallel emotional responding in the observer. Thus, when we see an unhappy friend, we may unconsciously mimic her frown, slumped posture, and subdued

tone of voice—and this physical mirroring may reinforce the sadness created in us by knowledge of her plight.

What is the effect of this emotional synchrony between observer and target? One socially important outcome seems to be greater feelings of rapport between the target and observer. Synchrony leads the interaction partners to feel more “in step,” involved, or compatible with each other. Thus, when Harry mimics Susan (almost always without awareness) as they talk, both parties are likely to feel that the interaction has gone more smoothly. In addition, evidence indicates that being mimicked leads us to be more helpful and generous to the mimicker. Thus, the net effect of emotional synchrony is to increase our feelings of closeness and connectedness with others and to lead us to act accordingly toward them.

Constructive Relationship Behaviors

Empathy can also influence relationships by fostering specific kinds of behavior that help maintain relationship health. This can happen in different ways. For example, routinely trying to imagine a social partner’s perspective will tend to produce more constructive behaviors—whether or not these perspective-taking efforts actually produce accurate inferences. If Susan genuinely tries to adopt Harry’s point of view, she is likely to treat him in a more tolerant, considerate, and tactful fashion.

Another major way in which this happens is through the feelings of compassion that empathizing evokes and the relationship between such feelings and constructive relationship behaviors. One beneficial outcome of sympathy is an increased willingness to offer help. Having compassionate feelings for another person is strongly related to offering help, whether that person is friend or stranger, whether it is easy to avoid helping or not, and even if doing so is costly for the helper. In addition, sympathy leads to several other constructive actions. For example, people high in a sympathetic disposition tend to disclose more openly to romantic partners and to invite such disclosure as well. In addition, people high in dispositional sympathy tend to display a pleasing social style. They are more considerate of their social partners, less

self-centered, and more even-tempered. They are also more likely to be supportive of their partners in times of stress.

What determines whether sympathetic feelings for social partners will occur? One answer is that some people are simply more prone to experience sympathy than others. In addition to such individual differences, certain situational characteristics influence the amount of sympathy that an observer is likely to experience. One of these is perceived similarity between observer and target; more similar targets tend to evoke more sympathy than dissimilar ones do. Another factor is whether the observer attempts to take the target's perspective; doing so makes sympathetic reactions more likely. In addition, we are especially likely to feel sympathy for others when we believe that they are not to blame for their difficulties. If Susan believes Harry failed an exam because he had the flu, she is likely to sympathize; if she believes he was playing video games instead of studying, sympathy will not be her first response.

Responding to Partner Misbehavior

Another important way in which empathy influences social relationships is evident when someone acts in a way that is hurtful to the partner. Such instances of misbehavior create short-term distress, but can also serve to create longer-term resentments and frustrations. In at least two ways, empathy can play a role in minimizing the impact of such events. First, empathizing with the misbehaving partner makes it more likely that an individual will respond to the provocation not with retaliation but with a more constructive, accommodating response—one that is less retaliatory and more understanding. For example, romantic partners who are high in dispositional perspective taking are more likely to respond to a partner's bad behavior by overlooking it, or by trying to understand it: They are less likely to respond in kind or to verbally lash out at the offending party.

Second, empathy for one's partner is associated with a greater likelihood of ultimately forgiving the partner for a transgression. This is important because such forgiveness makes it possible for partners to restore the relationship closeness that is

damaged when one partner transgresses. Forgiveness also helps release bitterness and anger and aids in emotional healing. Feelings of empathic concern are especially important here. In general, the more sympathy we experience for a transgressor, the greater is our willingness to forgive. In turn, such feelings of forgiveness lead to a reduced desire for revenge and a diminished desire to simply avoid the transgressor.

Reducing Aggression

Another way in which empathy can influence social life lies in its inhibiting effect on aggression. Although it has not been studied as extensively as the empathy-helping link, the association between empathy and aggressive behavior has received substantial interest, with two major mechanisms hypothesized to operate. The first is largely affective in nature. Witnessing the distress cues of another person (fearful expressions; crying) can produce sympathy or distress in the observer. Such feelings in turn may make the observer less likely to aggress against the victim because doing so tends to reduce the distress cues, and as a result, minimizes the observer's own discomfort. Another mechanism is more cognitive in nature. By taking the perspective of others, we may come to have more understanding and tolerance, and as a result become less likely to act aggressively toward them when provoked.

Some evidence exists for both mechanisms. For example, studies of delinquent and nondelinquent youth consistently find lower levels of dispositional perspective taking among the delinquents, and comparisons of abusive and nonabusive mothers display similarly lower levels of cognitive empathy among the abusive samples. The relation between perspective taking and aggressive behavior in the more general population is not as consistent, but is often found. Investigations of the link between emotional empathy and aggression in adults have fairly consistently found such a connection, with higher empathy associated with lower aggression; the evidence from studies of children has been more spotty. It seems likely that one reason for the somewhat inconsistent association between empathy and aggression is that it is often difficult to empathize with a potential target of

aggression—someone who by definition has frustrated or provoked you. Susan may find it difficult to feel sorry for Harry, and thus inhibit her verbal attack on him, when she is also angry at his thoughtless behavior. As a general rule, empathy is more likely to reduce aggressive responding when the provocation is not too extreme.

Cognitive Representations

A final way that empathy may influence relationships is a bit less obvious—by altering the way that we construct and store mental representations of other people. In particular, empathy can influence the degree to which our cognitive representations of self and other overlap or “merge.” Seeing the self and other as being connected rather than separate is something that frequently and naturally occurs in close relationships, and in collectivist cultures in which value is placed on the individual being integrated into larger social groups. Even in individualistic cultures, however, deliberately imagining the perspective of other people may increase the degree to which our mental representations of self and other overlap.

Such merging is associated with at least two important social outcomes. First, it leads to a diminished use of stereotypes when perceiving other people. That is, when our cognitive representations of self and other are more intertwined, we are less likely to see the other as simply possessing the stereotypical features of the social categories to which he or she belongs. Thus, if Harry empathizes with Susan and as a result represents her mentally in a way that resembles how he sees himself, then he is less likely to attribute characteristics to her that are stereotypical of her gender, age, or ethnicity. Second, self-other merging is also associated with greater liking for others and more positive treatment of them. For example, we are more likely to offer help to needy targets when we perceive a greater degree of self-other overlap with them.

In a sense, what happens in these cases is an expansion of the usual boundary that separates the self from others. Our “circle of moral regard” is increased, and as a result we come to value and care about the welfare of individuals who are ordinarily outside this circle. Although this process is probably more common when the other

person is not *too* dissimilar, it can occur even when the other is clearly a member of some identifiable outgroup.

Conclusion

Empathy has a generally positive effect on relationships, and this influence takes two broad forms. One is the beneficial impact that empathy has on the mundane details of everyday life. Unconscious and nearly constant mimicking of interaction partners produces an emotional synchrony that makes us feel closer and more attuned to those with whom we spend time. Dispositional empathic concern leads us to communicate more openly and to act in more considerate ways. The creation of overlapping cognitive structures corresponding to self and other produces greater feelings of similarity and liking. Thus, in a host of small and nearly invisible ways, empathy smoothes the rough edges of social intercourse and makes for more satisfying relationships.

But there is another way in which empathy makes its positive contribution to social life: It also operates during less routine, more dramatic moments—times of provocation, bad behavior, and betrayal by others. Perspective taking reduces the tendency to respond immediately and destructively to bad behavior by relationship partners, and thus helps avoid the escalatory cycles that often result from provocation. Perhaps even more important, feeling empathic concern for transgressors contributes strongly to a willingness to forgive, and with this, a readiness to forgo retaliation and embrace reconciliation. Empathy may therefore be said to have at least two important functions in social life—a *maintenance* function that operates all the time to keep relationships running smoothly, and *reparative* function that is apparent during times of relationship strain. Which of the two is more important is probably impossible to determine; a case might be made for either. What does seem clear is this: Because both are undeniably important to the long-term viability of relationships, empathy’s importance for the ongoing vitality of relationships is substantial.

EMPLOYMENT EFFECTS ON RELATIONSHIPS

A consideration of how employment affects relationships is broad because employment itself varies considerably (by hours, occupational prestige, physical location, and other conditions of the workplace including supervision, flexibility, and financial remuneration) and the effects of employment vary by the type of relationship under consideration (i.e., romantic, parental). Since the advent of industrialization and the consequent separation of domestic spaces and work spaces, work life and personal life have often been seen as separate spheres that did not affect each other. However, employment and personal life (including intimate partnerships such as marriage, romantic relationships, friendships, kin, and extended networks) affect each other in a variety of ways. This entry considers how the boundaries between

work and personal life are permeable and posits that they affect each other and how they vary according to gender, age (or life course), social class, and other aspects of context.

Boundaries Between Employment and Personal Life

Though workers have been socialized to “act as though” they had no other commitments, indeed work and personal life have always affected each other, if for no other reason than that paid work provides income for personal life, to be used by those in a worker’s household. Also, it has long been assumed that time in paid work represents time away from home. To work or not to work has been considered differentially problematic depending on gender: Men’s work has been seen as fulfilling a traditional relationship role of provider, whereas women’s work has been seen as competing for her time, attention, and commitment in fulfilling relationship roles such as care provider. Two frequently studied phenomena include relationship problems associated with men’s unemployment and problems posited as resulting from maternal employment (such as mother/infant attachment disorders). Joseph Pleck coined the term *asymmetrically permeable boundaries* to refer to how women are thought to bring their relationship concerns and statuses into the workplace (e.g., working mother), whereas men are thought to bring their work home (in actual work performed at home and in their financial rewards from work affecting the family’s social status).

How work affects relationships varies according to a person’s place in the life course and the relationships that are prominent in the person’s life at that time. A life course perspective applied to the work and family fields suggests that children and youth are affected by parental work. Youth can be affected by their own work in ways that may constrain their close relationships. Adults’ work can also shape their opportunities and time for relationships with family members.

The work and personal life field of study had its genesis in Employee Assistance Programs (EAPs) at large corporations that were faced with employees coping with childcare concerns. But a growing number of men and women in the labor force

today are from the baby boomer generation and may be faced with issues concerning care of aging parents. These workers are also faced with a labor market in which traditional retirement pathways are disappearing, and the literature shows that couples tend to plan joint or sequential retirement transitions together and that spouses and partners strongly influence retirement decisions.

Gender, life course, and context interact in determining the connections between employment and personal life. Women are active in the paid labor force fewer years than are men (29 years and 39 years, respectively), and women experience more work interruptions to full-time work than men. For example, women average 11.5 years away from the labor force to men's average of 1.3 years out of the market. Women often work part-time in the labor force, severely reducing their access to benefits. Women also earn less than men in wages and salaries, leading to financial disadvantages throughout their lives. By the age 65, only one in four women have gained the right to their Social Security earnings because of the requirements related to continuous employment.

Personal relationships provide a context for women and men in decisions they make about paid work. For example, women who can afford it reduce their paid work to care for young children, though they typically do not remain outside of the labor force for more than a few years per child. Couple dynamics such as power and consensus on gender role dynamics affect decisions about paid work. Care for an ill or disabled parent or spouse has a dramatic effect on employment. Wives who care for their husbands are much more likely to retire than are noncaregivers.

Processes of Connection Between Employment and Personal Life

Rosabeth Moss Kanter was the first scholar to attempt to articulate how work employment may affect family life via five processes. *Absorption* is a process in which work absorbs a person's time and attention even when they are home. Absorbing occupations can make demands on relationship partners, can make workers unavailable to relationship partners or children, or can even prevent the formation of satisfying relationships.

Time and timing processes concern the total time individuals spend at work and the way work hours are configured. Mothers in middle-class households often configure their paid work schedule around children's care and schooling, in this way promoting a certain type of relationship with their children, and maintaining a social appearance of being "at home." Some scholars have moved the concept of time absorption into a couple level by constructing measures of the family workday, in which both relationship partners are unavailable for couple interaction or interaction with children. Analyses of large national data sets have revealed a "time divide," partly because of work hours: Increasingly, workers in the same household exhibit profiles in which both adults either converge in not having access to enough paid work hours (underemployment), or else they converge in working large numbers of hours, especially in salaried positions (resulting in situations with both relationship partners averaging more than 50 hours per week).

The third process, *rewards and resources*, includes financial rewards from work, as well as benefits (including health care and pension) and symbolic assets that accrue through employment. Such rewards and resources can be of assistance to relationship partners because human capital (educational and occupational attainment) builds assets for individuals and families.

The fourth process is termed *occupational subculture*. It concerns the extent to which belonging to an occupation carries with it a subculture that includes coworker or colleague norms and involves an occupational identity held by individuals, which then interacts with identities held toward the worker by relationship partners and multiple identities held by workers. Individuals are thought to be socialized into certain occupations, often through social interaction with significant others. These occupations are associated with particular skill levels, educational requirements, and financial rewards, all of which combine to construct the social class of the worker, which in turn have been connected to living conditions and interaction patterns in marriages and with children. Annette Lareau, following Mel Kohn's *Class and Conformity*, documented via ethnographic methods the processes parents used to interact with their children, preparing children to take their parents'

places in society. For example, middle-class parents negotiated and explained rules, coached their children to interact with professionals, and carefully guided their development, whereas working-class parents used more authoritarian strategies in which their children submitted to authority and spent time in unstructured ways.

The final process is termed *emotional spillover*, and it addresses how emotional experiences at work can be carried into the worker's after-work relationships. Emotional spillover can be divided into positive carryover, negative carryover, and energy deficit. Spillover between work and personal life, as well as between personal life and work, can be positive (facilitation) in some domains and negative in others (conflict). Stress at work has been associated with men's withdrawal from spousal interaction and is an example of negative carryover from work to personal life. Scholars have attended to the bidirectional connections between paid work and personal relationships, articulating a nuanced set of four potential patterns: work-to-family facilitation, family-to-work facilitation, work-to-family conflict, and family-to-work conflict. Finally, energy deficit refers to situations when work is a boring or monotonous experience, leading the worker to feel lazy and depleted, which in turn can result in not engaging others at home.

Relational Consequences of Employment Processes

Researchers have moved beyond an initial focus on status regarding employment and personal life (i.e., employed or unemployed, married or unmarried, partnered or single, parent or nonparent) toward specifying how work is configured for a family and how it is experienced. Ann Crouter wrote in 1994 about the tendency of scholars to focus on one particular side of the "work-family equation": that is, focusing on aspects of work such as work hours or shift (e.g., night shift or part time), workplace (e.g., telework, commuting, work travel), or focusing on aspects of family life (e.g., transition to parenthood in a particular ecological niche such as working class or youth transitioning to adulthood in view of their developing romantic relationships in the context of poverty). Crouter endorsed the concept and the difficulty of

attending to both sides of the work-family equation simultaneously.

Theoretical underpinning can provide students and researchers with fruitful ways of inquiring about how employment might affect personal life. Theory has traditionally considered commitment to work as taking away from commitment to personal relationships. Early role theory notions regarded multiple roles as threats to strong commitments and involvements in relationships. Stephen Marks challenged this conceptualization with the expansion hypothesis that human time, energy, and commitment are not necessarily limited. Building energy into personal relationships can create a synergistic effect that enhances job performance. How people feel and enact their work roles can have positive connections to their personal lives and relationships as well as negative. Coworkers, for example, can provide an excellent source of supportive relationships (e.g., camaraderie, friendship) that can benefit personal life. Likewise, work relations that are problematic or conflict ridden may create tensions that are carried into the home or into other personal relationships.

Future work concerning employment and personal life will benefit from the gender, life course, and contextual perspectives. The gender perspective forces us to question assumptions underlying roles in families and at work related to men and women. A life course perspective compels us to consider historical and social trends and policies, particularly in birth rates, childbearing, and aging. A recognition of context guides us to consider the complexity of work experiences and personal and family life, including the problem of bidirectionality, such that employment and personal relationships provide contexts for each other. Individuals face decisions and challenges around securing rewarding work and meaningful relationships. Although some situations can be modified through active construction of solutions and partnerships (e.g., sharing family work and responsibilities), other situations are structurally embedded and cannot be easily changed, if at all (i.e., gender, age, social class). The demands of work often require workers' time, energy, and commitment, but at the same time, workers' personal relationships may make similar demands. Flexibility at work and in personal relationships in the face of potential conflicts is useful, but not available to

everyone at every point in their lives. Because individuals and work organizations may be highly invested in maintaining and enhancing satisfaction in employment and relationships, increased scholarship and growth in programs to improve work-life balance are likely.

EMPTY NEST, EFFECTS ON MARRIAGE

The empty nest occurs when the last child leaves home and parents no longer have coresident children. The transition often is not permanent. About 40 percent of young adults return to live with their parents. Most often, these returns are short-lived, for 1 or 2 years. Parents' housing and financial support helps children negotiate the transition to adulthood as they launch careers, change jobs, or acquire more training. For many couples, the nest-leaving stage entails a process during which children leave, return, and leave home again. This entry describes how transitions into and out of the empty nest affect marital interaction and happiness.

Research on the "U-shaped curve" of marital satisfaction has suggested a linkage between the empty nest and marriage. The key notion in this research is that raising children is stressful and thus detrimental to marital happiness. Researchers assume that certain stages of childhood are more stressful for parents than are others, especially adolescence. Thus, marital satisfaction is expected to decline with the birth of children and to reach its lowest level when couples are parenting teenagers. In numerous cross-sectional studies, declining happiness in the early years of marriage has been attributed to the demands of parenting minor

children. Increases in happiness later in marriage (the upturn in the “U”) are linked to lessening parental responsibilities as children leave home. Longitudinal studies also suggest that the empty nest leads to increases in marital happiness, perceived marital equity (the balance between what each spouse gives to and receives from the marriage), and in women’s well-being. Data from a long-term study of married couples showed that, after the initial sharp decline from the newlywed stage, marital happiness declined slowly until 40 years of marriage, then declined steeply again. The presence of children in the household had negative effects on marital happiness across the life cycle. Children’s home-leaving and the empty-nest transition slowed the general decline over time in marital happiness.

The empty nest may alter the risk of divorce. This effect depends on marital duration. National survey data in the United States suggest that the risk of divorce increases after the transition to empty nest, but only for couples who reached this phase before 20 years of marriage. The effect of the last child’s departure on the risk of divorce is negative for couples married more than 30 years. Thus, the impact of nest-emptying on marital stability may depend on earlier family events, including the timing of the birth of the first child and the spacing of subsequent children. These events will influence whether the empty nest occurs earlier or later in the marriage.

Coreidence With Adult Children

Most of what is known about the impact of children on marriage concerns the influence of parenting young children, which has detrimental effects on marriage. Research has shown that the effects of the empty-nest on marriage are strongest when the last child to leave is relatively young (age 18 or 19) and the transition marks an end to the active parenting of minor children. Less is known about the consequences for married couples of coresiding with their grown children.

The likelihood of parents having a coresiding adult son or daughter is high. U.S. Census data show that about half of men and women aged 18 to 24 years live in the home of one or both parents. Sharing a home with adult children may be

harmful to marriage. Privacy may suffer. Research shows that coresidence exerts a negative effect on marital intimacy and sexual activity. The issue of “Whose home is it?” may loom large. Do parents have the right to make rules for their adult children, impose a curfew, monitor children’s whereabouts, or forbid a dating partner to sleep over? Parents and adult children may dispute the children’s financial contributions to the household and their responsibility for housework. Nonetheless, recent longitudinal research suggests that satisfaction or dissatisfaction with coresidence may actually have few implications for marriage. Russell Ward and Glenna Spitze examined the degree to which the burdens of parenting affected married couples as adult children moved into and out of the parental home. Although children’s home-leaving led to more time together for married couples, the presence of adult children was unrelated to marital happiness and the frequency of marital disagreements. The long duration of the marriages in this study may have protected spouses from the potentially negative effects of continued or resumed residence with adult children.

Parental perceptions of how well adult sons and daughters are doing in life may be more important to parents’ well-being than living arrangements are. Regardless of where their adult children live, parents feel better about themselves when they perceive their offspring as doing well in life, both in terms of achievements and social-emotional well-being. Adult children’s problems (e.g., with finances, illness, career, or marriage) have been linked to poorer well-being for parents and increased strain in family relationships. Having difficult relationships with adult children may itself lower parents’ marital quality. Parents’ satisfaction with having coresident adult children tends to be higher when they perceive their sons and daughters are making progress toward self-sufficiency. Parents grow unhappy with the coresident living arrangement when adult children appear to be floundering in their education, career, or relationships.

Gaps in Research

Many questions concerning the empty nest and marriage remain unanswered. Long-term studies

are needed to disentangle empty-nest effects from changes related to marital duration. The removal because of divorce of poorer quality marriages from the population of couples may account for the differences in marital happiness observed when comparing empty-nest couples (representing surviving, long-term marriages) with marriages with shorter durations. Little is known about the effects of the empty-nest transition in stepfamilies and blended families, or in extended family living arrangements where married couples coreside with relatives or nonrelatives. Almost nothing is known about racial and ethnic variation in response to the empty nest. A growing variant of the "refilled nest" is having coresident grandchildren. The number of grandparents raising grandchildren has increased dramatically since the 1990s. According to U.S. Census data, 5.6 million children lived with a grandparent in 2002, including 10 percent of children under 6 years old. The few studies in this area suggest that taking responsibility for rearing grandchildren may have substantial negative effects on the marriages of elderly and midlife parents.

END OF LIFE, RELATIONSHIP ISSUES DURING

At the *end of life*, everything drops away except that which is most important: for most people, it is the relationships that have made up their lives. As death approaches, relationship issues that have developed throughout people's lifetimes may be magnified and examined more closely for reflection and consideration. What is important relationally at the end of life can often be identified by the messages conveyed during final conversations. The five primary themes that emerge in final conversations are love, identity, religion/spirituality, everyday activities, and difficult relationship issues. The purpose of this entry is to describe these five message types as they reflect what occurs in conversations at the end of life.

One thing to consider as these messages are reviewed is the encouraging and empowering nature of the conversations that occur while people face the reality of death and loss of someone with whom they are close. These interactions often arise in the midst of strong and frequently negative emotions that accompany death such as grief, fear, sadness, and anger. Impending death brings with it cognitive reactions that include a loss of control, denial, uncertainty, and even avoidance.

At the end of life, relationships also have to coexist with three pervasive challenges: The first challenge is the chronic physical pain that frequently accompanies death. To manage the pain, the dying often must take powerful medications that can leave them in psychologically altered states (i.e., hallucinations, mental confusion, or sleeping for longer periods). The second challenge is the chronic stress that is commonly experienced by both individuals in the close relationship. It is difficult to behave normally in the midst of constant worry and strain. The third challenge is the cultural expectations that have made death unnatural, morbid, and a taboo topic.

In addition to the challenges that surround relationships at the end of life, awareness that death is near also gives people in relationships many valuable and irreplaceable opportunities. An impending death gives people permission to say no to less important, although seemingly more demanding, parts of their lives. People (both those who are

dying and their loved ones) tend to slow down their active lives and, for a brief time, focus intently on their relationships. Whereas unexpected sudden death limits many of the choices and opportunities for the resolution of issues in close relationships, foreknowledge of impending death gives the gift of time to communicate in ways that may have a profound impact on the relationship as well as on the individuals. Final conversations provide opportunities to create new memories, cherish old ones, and find closure where needed.

Final Conversations Themes

Love expressed in conversations at the end of life emphasizes the importance of connecting and expressing affection in relationships. The clarity accompanying impending death reveals the importance of relationships and love for many people. The need for experiencing and expressing love is a constant throughout life and is magnified at the end of life. Love is communicated through verbal messages and nonverbal actions.

Identity is a conversational theme that highlights the importance of relationships for discovering and confirming information about the self. Only those individuals who are a part of the dying one's inner circle are typically allowed time to talk and visit with him or her. Thus, at the end of life, each party to the relationship is considered an important mirror for the other in that they have a final opportunity and often the genuine motivation to reflect the most honest likeness of who they really are or who they could become. Communication at the end of life can serve as a reminder of the impact relational partners' have on each other's self-concept and self-esteem.

The appearance of *spirituality/religious* messages at the end of life is consistent with research that suggests that, when people are confronted with death, they often search for meaning by exploring religious and spiritual belief systems. When medical science can no longer provide any answers or hope, spiritual/religious messages frequently offer the only consolation available in the face of impending death. Thus, talking about issues pertaining to faith at the end of life can ease the suffering for both the dying and the living.

Everyday talk at the end of life encompasses ordinary and mundane conversations and routine

actions. Relationships are typically made up of the routine and ordinary, rather than constant turning points or momentous events, so why should communication at the end of life be any different? It is far too difficult for both the dying and the living to have deep conversations all of the time. Everyday talk gives people at the end of life moments of normalcy within their relationship and allows people to continue their relationship with one another until the moment of death.

The theme of *difficult relationship issues* brought up in end of life conversations focuses primarily on people "cleaning up" their relationships so that they are not left with, or do not leave with, regrets. If there had been a difficult relationship before the terminal diagnosis, relational partners may have a strong desire to search for healing and reconciliation. Letting go of anger and recognizing that people are flawed are often necessary to healing at the end of life. Interestingly, loved ones frequently seek ways to reconcile without threatening the face of the person who is dying.

These five messages reflect the importance that relationships take on for people at the end of life. The memorable talk is not about things but, rather, about the people and the relationships in their lives. The finality of endings, such as the one that comes with death, is often a catalyst for people to reflect, reframe, and reprioritize their lives. The Socio-emotional Selectivity Theory suggests that endings, such as that of an impending death, gives people permission to choose and prioritize events in their lives in such a way as to intensify their emotional commitment, to strengthen their relational ties, and to create an urgency regarding the most important things in life—their close relationships. For instance, at the end of life, individuals have the ability to affect their relationship with one another in potentially profound ways: through sharing important moments; by becoming more open, honest, and revealing to one another; by acknowledging their thoughts, fears, and concerns about death; and by talking about how to go on living after the death. Relationships can be made stronger because people finally deal with things that have been difficult or impossible to cope with in the past. Individuals can resolve differences, as well as ask for or offer forgiveness to one another.

Ultimately, taking care of relationship concerns, as well as contemplating and embracing their

relationship at the end of life, helps emotionally prepare all of the relational partners for the impending loss and allows people to let go of one another in ways that may be easier than originally thought possible. Death is usually still followed by grief and relational loss, but the loss is somehow more endurable and regret is often reduced when care and attention are given to relationships at the end of life. Finally, through the awareness that death and the end of their relationship is near, people have an opportunity to say a meaningful and heartfelt goodbye. Closure and completion of a life and its relationships is a communicative accomplishment.

contrast, enemyship does not figure prominently in the experience of people whose lives tend to inform scientific imagination; as a result, relationship researchers have devoted little attention to the topic. Against this background, the most important contribution of research on enemyship may be what it reveals about the broader cultural grounding of relationship in general. This entry describes the broader contextual forces that underlie (a) the prominent experience of enemyship in diverse West African worlds, (b) the sense of freedom from enemyship in diverse North American worlds, and (c) the relative absence of enemyship as a topic in relationship science.

Prominence of Enemyship in West African Worlds

To understand the concept of *enemy*, it is useful to begin with the prominence of enemyship in many West African worlds. To say that enemyship is prominent in these worlds does not mean that overt acts or explicit declarations of malice are necessarily common or severe. Instead, enemyship is prominent as a collective representation that people appropriate when relevant—for example, an urban migrant wondering about resentment of rural relatives because of perceived insufficiency of remittances, a student worried about sabotage (by classmate competitors or envious relatives) in preparation for an examination or contest, a prosperous farmer or business owner concerned about malicious envy of neighbors, or people suffering from illness or misfortune—to make sense of everyday events. As such, enemyship is evident in cultural products (e.g., stickers that proclaim “let my enemy live long and see what I will be in the future”) and cultural practices such as *sorcery*, a set of techniques for sending harm to enemies or defending oneself against such harm; *divination*, a technique for analysis of misfortune that frequently produces accusations of interpersonal sabotage; and *infant seclusion*, a practice whereby mother and child remain indoors for several days after birth to protect against malicious envy.

Besides observable representations, the prominent concern with personal enemies also extends to private experience. Across diverse West African worlds (but especially rural areas and other spaces

ENEMIES

Enemyship refers to a *personal* relationship of hatred and malice in which one person desires another person's downfall and tries to sabotage the person's progress. This definition emerges from field research in various West African worlds, where enemyship is a prominent concept that informs experience of intimate relationship. In

that promote embeddedness in dense, overlapping networks of relationship), the majority of people—sometimes as high as 90 percent—report that they are the targets of personal enemies. A typical response goes something like this: “I don’t know my enemies, but I know that I have them. One day something will happen to me, and then I will know that this person has been after me all along.” Although most people in most circumstances do not suffer undue anxiety from the possibility of enemyship, they may become acutely concerned about potential malice from hidden enemies in certain situations. Likewise, although people may not identify a specific person who bears malice toward them (and typically deny that they bear malice toward anyone else), they have in mind certain interpersonal locations—including such intimate relationships as friends and relatives—from whom they anticipate malicious harm. In general, responses suggest that the prominent concern with personal enemies in West African worlds is a collective representation. People base their expectations of malice not on personal experience of an enemy relationship but on default assumptions about the relative “stickiness” of relationship in worlds that promote a sense of inherent connection, interdependence, and embeddedness in context.

Freedom From Enemyship in North American Worlds

The implicit contrast is with the relative absence of enemyship from experience of people in North American worlds and other spaces of globalized affluence. Across diverse North American settings (but especially urban areas, university campuses, and other spaces that promote mobility across non-overlapping networks of relationship), the majority of people—again, sometimes as high as 90 percent—*deny* that they are the targets of personal enemies. Although they recognize potential for enemyship in special situations (e.g., competitors in business, politicians in an election, litigants in a court case), the default assumption in these settings is that normal people in normal circumstances do *not* have enemies—especially not from intimate spaces like friends or relatives. A typical response goes something like this: “I don’t think I have enemies. I haven’t done anything to make

people hate me. There may be dislikes and conflicts, but I choose to ignore them. Why create that kind of situation? It takes too much work.” As this response suggests, many people report cases of interpersonal dislike that might otherwise qualify as relationships of malice, but they base their denial of enemyship on default assumptions about the relatively frictionless nature of relationship in worlds that promote a sense of inherent insulation, independence, or abstraction from context.

Even in the relatively infrequent cases in which people in North American settings *do* claim enemies, their responses diverge from claims about enemyship in West African settings in ways that reveal broader constructions of relationship. First, people in North American settings are more likely than are people in West African settings to refer to intergroup rather than interpersonal enemies, a pattern that suggests a propensity to experience belongingness in collective rather than relational forms. Second, people in North American settings who do claim personal enemies are more likely than are people in West African settings to claim a mutual relationship of hatred, thereby implying that they somehow *choose* to participate in this relationship. Third, research suggests that people in North American settings who discover that they are the target of enemyship often express surprise and dismay that they have somehow provoked hatred, but eventually interpret this hatred in terms of the enemy’s abnormality and pathological obsession.

In general, responses such as these suggest that the sense of freedom from enemies in North American worlds is not a natural or default state; instead, it reflects particular constructions of reality—specifically, a “free market” of relationship in which people are at liberty (but also compelled) to create their own connections. The frictionless quality of relationships in these settings not only provides few opportunities for interpersonal conflict, but also provides ample opportunities to avoid relationships in which conflict does develop.

Absence of Enemyship as a Topic in Relationship Science

Reflecting the cultural worlds that disproportionately inform scientific imagination, enemyship is

nearly absent as a research topic in relationship science. A PsycINFO search in April 2008 using the root *enem**, returned 5,085 items, compared with 57,880 items for the root *friend**. (Similarly, searches of *hate* or *hatred* compared with *love* returned 7,521 and 39,612 items, respectively.) Of these items, many described behavior of non-human animals (e.g., the concept of *dear enemy*, which refers to a territorial animal's ability to discriminate between distant strangers and familiar neighbors). Another large set of items referred to ethnic prejudice and other forms of intergroup hatred (e.g., war, terrorism, hate crimes, and genocide). In the end, only 51 items remained in a search limited to entries for *enem** that matched the descriptor field *interpersonal relationships*. (Similar limitations on searches of *friend**, *love*, and *hate* or *hatred* retained 1,133, 1,010, and 86 items respectively.)

Moreover, the cultural grounding of relationship is evident in features of research that do consider personal enemyship, as well as in the relative absence of research about personal enemyship. A common form in which the topic of enemyship appears is in the context of research on *paranoid cognition*: the irrational or exaggerated perception—often associated with delusions of grandeur—that one is the target of others' harassment, harm, or malicious scrutiny. The cultural grounding of relationship is evident in this formulation to the extent that the paranoid label constructs the experience of enemyship as a delusional deviation from default reality in which normal people in normal circumstances do not have enemies.

Similarly, the broader cultural grounding of relationship is evident in studies focused on the need for enemies. Why do people need enemies? Research suggests that interpersonal enemies serve as both (a) a stimulus to individuation by helping people define their physical and psychological boundaries and (b) a self-protective tool in times of threat by contributing to the maintenance and regulation of a favorable self-image or superiority. However, the broader cultural grounding of relationship is as much evident in the question of why people need enemies as it is in particular answers to the question. Specifically, the question itself implies a “free-market” construction of relationship as voluntary association in which development and maintenance of enemyship are the products of personal choice.

From this perspective, the idea of a “need for enemies” provides a motivation for the otherwise puzzling choice to create and maintain an otherwise destructive relationship. This set of assumptions starkly contrasts with responses of people in West African worlds, who experience personal enemyship as the default product of embedded interdependence rather than a need or choice.

Another set of studies about personal enemies that reveal the broader cultural grounding of relationship concerns *mutual antipathy*: relationships of reciprocated, strong dislike among interaction partners. Again, the notion of *mutual* antipathy resonates with a construction of relationship as voluntary association to the extent that it implies some degree of willful participation in the relationship (rather than being the unwilling target of another person's hatred). Research on mutual antipathy is most prominent in the context of peer relations, which typically links these tendencies to negative developmental outcomes and externalizing behaviors such as aggression.

A particular interest of research has been the relationship between mutual antipathy and overt forms of aggression, such as physical violence and bullying, that popular understandings depict as typically male expressions of enemyship. However, researchers have recently shown increased interest in the topic of *relational aggression*: more subtle acts of violence, such as spreading rumors or gossip and ignoring or excluding others from peer groups, that popular understandings depict as typically female expressions of enemyship. For present purposes, there are two noteworthy features of relational aggression.

The first point concerns the extent to which the concept of relational aggression resonates with West African conceptions of enemyship. When people in West African settings talk about the harm that enemies do, they typically mention the sort of gossip and exclusion behaviors that researchers have identified as relational aggression. Together with the association of relational aggression with women and girls (at least in North American settings), this confluence suggests the extent to which relational aggression is a gendered and culturally grounded phenomenon rooted in interpersonal connection and interdependence.

The second point concerns the status of enemyship as a relational phenomenon. A “free-market”

construction of relationship as a product of voluntary choice promotes an asymmetry in experience of positive and negative relationship; that is, people feel free to create and maintain rewarding relationships and to avoid unrewarding relationships. In turn, this asymmetry promotes both an understanding of relational connection as prosocial behavior and, by extension, an understanding of antisocial behavior as something antithetical to relationship. One manifestation of this understanding is the tendency to conceive of conflict as part of a dissolution stage of relationship—a signal that connection and relationship are giving way to autonomy and individuation—rather than something inherently relational in its own right.

In contrast, research on relational aggression—and the topic of enemies in West Africa—highlights the extent to which enemyship is a relational phenomenon. Many West African languages have sayings—such as “Hatred comes from the house” or “An insect that bites you comes from inside your cloth[es]”—that explicitly recognize the association of enemies with close or intimate relationship. From this perspective, enemies are typically not strangers, acquaintances, or other people whom one barely knows. Instead, enemies are often people who inhabit intimate spaces of close relationship. In short, enemyship is not the antithesis of relationship but, instead, is itself the product of intimate connection.

ENGAGEMENT AS A RELATIONSHIP STAGE

This entry discusses the history, contents, and functions of engagement as a premarital phenomenon. Engagement means that the basic courtship is over, and the couple plans to marry at some future time. Engagement indicates that a private love relationship has become public. As a formal period between courtship and marriage, the term *engagement* is not used worldwide. However, there are preparations for marriage in all societies, such as the paying of bridewealth or dowry. And although formal engagement is primarily Western European, it is found in a variety of cultures. As an example, among the Hopi Indians of the southwestern United States, the family of a potential bride prepares food and takes it to the family of the potential groom. If the food is accepted and the marriage approved, his family reciprocates with food for her family, and the couple is engaged.

History

In Europe, the announcement of the intention to marry can be traced to Pope Innocent III's 1215 decree: “Marriages are to be . . . announced publicly in the churches by the priests during a suitable and fixed time, so that if legitimate impediments exist, they may be made known.” In some places, this was called “the reading of the banns” and was one way of preparing for and

legalizing marriage. Innocent's decree is the best-known and most historically visible basis for formal engagement. The state of being formally engaged is "betrothal." In the United States, the average length of an engagement is 16 months.

The engagement ring can be traced as far back as the 15th century among high-status couples. It is worn on the woman's fourth finger of the left hand in English-speaking countries, with that finger considered to contain the *vena amoris*, or the "vein of love." In Continental Europe, the ring is worn on the right hand. In the United States, some 75 percent of brides-to-be receive an engagement ring. Though much less frequent, during the 20th century in Canada and the United States, engagement rings also began being given by the woman to the man. Some formal engagements include an engagement party, hosted by the bride-to-be's family. It usually takes place from 6 months to a year before the wedding.

In the United States, one-third of engaged couples hire a wedding consultant—though this is more likely in upper-income families. Recent U.S. statistics show that during the engagement period, couples and their families spend some \$4 billion on furniture, \$3 billion on housewares, and \$400 million on tableware in preparation for the marriage and setting up the household.

The sexual revolution and an increase in middle-class cohabitation during the second half of the 20th century had a substantial effect on the practice of formal engagement. Though Alfred Kinsey's samples were hardly representative, his 1950 report showed that half of premarital sex was considered "engagement sex" among women—that is, it was almost exclusively with one's fiancé, and often took place just before the wedding. But by the early 21st century, sexual activity and formal engagement have become separated factors in relationships. Also, cohabitation has caused a reduction in the frequency of formal engagement because the transition may simply be from cohabitation into marriage.

Engagement Characteristics

What takes place during engagement depends on the type of engagement. In a short, romantic engagement, the couple prepares for marriage,

and often engages in intense physical contact. The engagement may involve a social event or party and the purchase of items for the marriage—as noted previously.

A long, separated engagement may occur when one partner is away in college, or working, or in the military. There are two distinct and seemingly contradictory aphorisms regarding the effect of separation: "absence makes the heart grow fonder" and "out of sight, out of mind." However, under conditions of separation, a couple may drift apart, or may at least question whether exclusivity is either desirable or possible. The marital equivalent of the separated engagement is the commuter marriage, where couple members live in separate communities for some period.

Third is the inconclusive engagement. Here, the couple postpones marriage because of economic considerations, deference to parental demands, or indecisiveness and uncertainty. According to the *Guinness World Records*, the longest recorded engagement was between Octavio Guillen and Adriana Martinez of Mexico, who took 67 years to make sure they were "right for each other." Most engagements are at least 65 years shorter. Many lengthy engagements simply do not survive until marriage, though there are no data showing that they are less likely to survive than are short engagements.

About a quarter of engaged couples break up temporarily, and some break up permanently. The causes of breakups may be simple loss of interest, recognition of an incompatible relationship, or the desire to change or "reform" the prospective mate. A fourth reason for breakup is that the parents of one or both engaged persons actively intervene to forestall the marriage or break up the engaged couple. A result of premarital sexual activity may be that the engaged couple loses sexual interest in each other during engagement.

Functions of Engagement

In some societies, the exchange of gifts between kin groups signals the intention of a couple to marry and obligates the families to each other. In the Western World, formal engagement gives the families of the couple the opportunity to become acquainted.

Even today, engagement usually sends a “hands-off” message to others. It also gives the opportunity to strengthen their couple identity and to become acquainted with future in-laws. Though not required, a premarital medical exam, especially one involving genetic testing, can provide information about potential health problems. Knowing about health conditions may even presage the eventual necessity for one party to care for the other—as in the case of diabetes. The medical exam may also prepare a couple for both pregnancy prevention and for pregnancy. Each partner is given the opportunity to talk over questions about the coming marriage with the physician.

Engagement frequently includes premarital counseling, religious or not. This is especially useful when the partners are of different religious, ethnic, or racial backgrounds. Such differences may seem inconsequential during courtship, but may be found to matter when marriage and parenting are considered with a counselor. Counseling may help illuminate the “blindness” that comes from being in love. Various instruments are available for assessing a couple’s relationship compatibility, such as the “Prepare” program by David Olsen from the University of Minnesota. Finally, even if a couple has been living together, engagement signals to families and friends the intent to legalize their life together.

Though formal engagement is less prevalent and functional than it was in Western societies 50 years ago, it is still a prelude to many marriages.

ENVY

Envy is a negative, unpleasant, and often-painful emotion that is elicited by comparison with another person or group that has something that one either desires or wishes that the others lacked. This might include an attribute, a possession, a social position, an achievement, luck, or quality of being. The experience of envy consists of a blend of (a) sadness or distress over one’s shortcomings or one’s inferiority to the envied person, (b) admiration for the envied person, (c) longing for what the envied person has, (d) anger and displeasure over the envied person’s superiority, and (e) resentment of the inequitable situation. Compared with more basic emotions (e.g., fear, anger, joy, sadness, surprise, and disgust), envy can be considered to be a more complex emotion involving a high degree of cognitive appraisal or cognitive elaboration. Like other cognitive emotions (such as disappointment, guilt, or regret), envy is associated with areas of the neocortex—the part of the brain that supports the majority of our most complex cognitive abilities. As such, envy is more influenced by conscious thoughts than basic emotions are. This entry first addresses the relation of envy with jealousy, then describes the most important source of the envy, that is, comparisons with others and addresses the hostile nature of envy. The entry concludes with discussion of the possible functions of envy.

The emotion of envy is often confused with that of jealousy. One important reason for this is the semantic overlap in the common language use of the term jealousy. Whereas *envy* will almost always have a single meaning (i.e., an unfavorable comparison with another person), *jealousy* is commonly used to mean both jealousy (i.e., a threat of losing someone to a rival) and envy (e.g., “I’m jealous of his house”). An additional reason for the confusion is the tendency for both emotions to co-occur. For example, a rival can be threatening and

evoke jealousy precisely because he or she has enviable qualities. Despite the semantic overlap in the use of the term *jealousy* and the frequent co-occurrence of the two emotions, envy and jealousy are quite different emotions. They are elicited by distinct appraisals and produce distinctive emotional experiences. Envy typically involves two people and occurs when one lacks something enjoyed by another. In contrast, jealousy typically involves three people and occurs when one is threatened by a (feared or actual) loss of an important relationship to another. Furthermore, unlike envy, the experience of jealousy involves fear of loss, anxiety, suspiciousness, and anger about betrayal.

Envy tends to arise because the advantages enjoyed by others have important consequences for how people feel about themselves. Being confronted with another person's relative superiority reflects badly on the self and usually results in envy and the accompanying painful blend of feelings of inferiority, hostility, and resentment. Thus, unfavorable social comparisons are at the heart of envy. Social comparisons that involve someone who is psychologically close (e.g., someone who is similar in background, age, and social class, or shares similar interests, aspirations, values, work, and status) are both more likely and have more impact than do social comparisons with others who are less close. As such, social comparisons with proximate others are more likely to elicit envy. In addition to the impact of psychological closeness, the emotion of envy is also affected by the self-relevance (i.e., personal importance) of the comparative issue. For social comparisons such as these, the threat to people's self-esteem is especially strong and results in an intensified experience of envy. Thus, people envy others who are emotionally significant to them and are perceived to have outperformed them on issues that are important to their self-worth.

Throughout history, envy has been regarded as a moral wrong and a feeling to be avoided. For example, Christianity regards envy as one of the seven deadly sins, and Buddhism characterizes it as one of the six types of poison. The seemingly negative nature of envy is apparent under several conditions. For example, when people experience envy, their relative outcomes seem to be more important than absolute ones. Envious people seem willing to deprive others of what they have

or to destroy a desired advantage if they themselves cannot have it. In doing so, this might even involve sacrificing some of their own strengths, advantages, or resources. The hostile nature of envy also sets the stage for the experience of *schadenfreude* (pleasure derived from another's misfortune). A misfortune befalling an envied other can be pleasing because it removes the basis of envy. It transforms an invidious social comparison into a more favorable one, providing a relative advantage in comparison with the envied other. Thus, envy can be regarded as a hostile emotion that often prompts aggressive behaviors and establishes an antagonistic relationship to the more fortunate other. For these reasons, envy can be harmful and destructive to social relations.

Higher cognitive emotions such as envy seem to have been designed by natural selection to help our ancestors cope with an increasingly complex social environment. Envy may be viewed as an important marker or signal for those social comparisons that reflect poorly on the self in ways that are personally important. Less extreme experiences of envy may be valuable in motivating individuals to identify or search for opportunities for self-improvement (e.g., the development of competence and the acquisition of skills). Furthermore, envy emphasizes certain egalitarian principles in human relations and may promote an individual's self-assertion. Envy may also motivate people to derogate others whose favorable status is unjustified, thereby preserving equal relations. In this sense, envy may help solve problems related to group governance, problems that arise in several important contexts, including the allocation of resources and distribution of work.

EQUITY THEORY

In the 11th century, St. Anselm of Canterbury argued that the will possesses two competing inclinations: an affection for what is to a person's own advantage *and* an affection for justice; the first inclination is stronger, but the second matters too. Equity Theory, too, posits that in personal relationships, two concerns stand out: first, how rewarding are people's societal, family, and work relationships? Second, how fair, just, and equitable are those relationships? According to Equity Theory (as postulated by Elaine Hatfield, G. William Walster, and Ellen Berscheid), people define a relationship as equitable when "the rewards they reap from a relationship are commensurate with their contributions to that relationship." (In contrasting profit vs. equity, profit [i.e., rewards minus costs] is generally found to be a more important determinant of satisfaction than is equity.) According to the theory, couples feel most comfortable when their relationships are maximally profitable and they are getting exactly what they deserve from their relationships—no more and certainly no less. In this entry, we will discuss the logic behind Equity Theory, discuss techniques for assessing how equitable a relationship is, and discuss the consequences of fairness (or unfairness) in dating, newlywed, and long-term marital relationships.

During the past 25 years or so, social psychologists have become interested in the cognitive and emotional underpinnings of humanity's concern with social justice, fairness, and equity. Evolutionary theorists, for example, argue that for at least several million years, our ancestors engaged in complex social exchange. Thus, theorists contend, a concern with both reward and fairness is ancient and universal—"wired in" as part of the architecture of the human mind. Currently, most cross-cultural investigators, neuroscientists, primatologists, ethologists, and evolutionary psychologists generally agree that although social

definitions of equity may vary, a concern with profit, fairness, and equity may, indeed, be common in the animal kingdom.

Equity Theory (as articulated by Hatfield and her colleagues) consists of four propositions:

Proposition I: Men and women are "wired up" to try to maximize pleasure and minimize pain. (No surprise, then, that people are concerned with the rewards and punishments they receive in their close relationships.)

Proposition II: Society, however, has a vested interest in persuading people to behave fairly and equitably. Groups will generally reward members who treat others equitably and punish those who treat others inequitably.

Proposition III: Given societal pressures, people are most comfortable when they perceive that they are getting roughly what they deserve from life and love. If people feel overbenefited, they may experience pity, guilt, and shame; if underbenefited, they may experience anger, sadness, and resentment.

Proposition IV: People in inequitable relationships will attempt to reduce their distress via a variety of techniques—by restoring psychological equity (convincing themselves that an inequitable relationship is indeed fair), by restoring actual equity, or by abandoning the relationship.

A wife who feels guilty about "cheating" on her husband may, for example, restore *psychological equity* by convincing herself that her husband has probably been cheating on her for years; her wayward behavior is simply a case of "tit for tat." A woman who feels guilty about the fact that convention dictates that her poverty-stricken date ought to pay for dinner, concerts, and transportation may attempt to set things right by inviting him to dinner or pretending someone has given her free tickets to a play—thus restoring *actual equity*. Finally, a husband who feels with his wife it's all give (on his part) and all take (on hers) may elect to leave the marriage.

Historically, different cultures and societies have possessed different visions about what constitutes social justice, fairness, and equity. Participants may not always agree about the equity of their relationships; outsider observers might have yet another view about who is getting more from a

given relationship. In defining *equity*, people may focus on a wide variety of decision rules and inputs and outcomes. Some dominant views: “All men are created equal” (equality). “The more people invest in a project, the more profit they deserve to reap” (capitalism). “To each according to his need” (Communism). “Winner take all” (dog-eat-dog capitalism). “It’s a man’s world” (traditional hierarchy). Nonetheless—whatever the cultural rules—in all cultures, social justice, fairness, and equity are deemed important.

Social psychologists have developed a variety of measures to assess how fair and equitable people perceive a given relationship to be. In practice, however, people’s perceptions are often assessed by asking, “Considering what you put into your dating relationship or marriage (compared with what you get out of it) and what your partner puts in (compared with what he or she gets out of it), how does your dating relationship or marriage ‘stack up’?” On the basis of their answers, persons are classified as perceiving themselves as overbenefited (receiving more than they deserve), equitably treated (receiving exactly what they deserve), or underbenefited (receiving less than they deserve) from their close relationships. Other measures of equity exist. In one detailed measure, Hatfield and her colleagues asked men and women who were dating, living together, and married to indicate how fair and equitable they considered their relationships to be via a 22-item scale: The areas of interest included such *personal qualities* as appearance, intelligence, and social grace; *emotional concerns*, such as physical affection and understanding and concern; and *day-to-day concerns*, such as contributing to household expenses and helping around the house.

Some researchers, such as Susan Sprecher, have developed “Exchange Orientation” scales, designed to assess the concern of individuals with justice, fairness, and equity. She argues that some people are especially concerned about giving their partners all that they deserve, whereas others are primarily concerned with “Am I getting my fair share?”

Regardless of societal definitions or one’s own concern with equity, consideration of equity has been found to be important in a wide variety of cultures and relationships—social relationships, romantic and family relationships, friendships, helping relationships, and work relationships.

Equity in Love Relationships

Scholars have discovered that how concerned couples are with reward and equity depends on relationship stage. When couples are first dating, they participate in a kind of “dating and marriage marketplace,” in which considerations of reward, fairness, and equity loom large. Once men and women are deeply committed, however, they become less concerned about day-to-day reward and equity. Should a relationship deteriorate, however, couples—knowing (perhaps) that they will soon be back on the market—may begin to worry about “What’s in it for me?” and ask, “Do I deserve better?”

In the Beginning

In fairy tales, Prince Charming often falls in love with the scullery maid. In real life, however, people generally search for “suitable” partners. Considerable evidence indicates that when people are attempting to decide whether or not to date or mate, potential reward and equity matter. Specifically, researchers find the following: (1) The more socially desirable men and women are—be they gay, lesbian, or heterosexual—the more social assets they will demand in a “suitable” potential date or mate. (2) Men and women tend to fall in love with partners who possess similar assets and liabilities. Dating couples generally end up with partners similar to themselves in self-esteem, attractiveness, intelligence, education, and mental and physical health (or disability), among other things. (3) Market considerations have been found to affect men and women’s romantic and sexual choices, the amount prostitutes charge for “risky” sex, and the sexual bargains men and women craft in prison. (4) Profitable and equitable dating relationships are satisfying and comfortable relationships; inequity is associated with distress, guilt, anger, and anxiety. (5) Profitable and equitable dating relationships appear to be more stable (and more likely to lead to more serious relationships) than are inequitable relationships.

Thus, research indicates that in the early stages of a dating relationship, considerations of the marketplace prevail. Men and women will attempt to attract a socially attractive partner; they are profoundly concerned with how rewarding and

how equitable their budding relationships appear to be.

In Close, Intimate Relationships

Theorists agree that casual and intimate relationships are different. In *Equity: Theory and Research*, Elaine Hatfield and her colleagues pointed out that casual relationships differ in a number of ways from intimate connections. In close, intimate relationships, for example, couples feel more intensely about one another, share more of their lives, have (and expect to have) a longer time to spend together than do couples in fleeting affairs. Married and other committed couples, who assume they will be together for a lifetime, are likely to be sanguine about momentary injustices, confident that “it will all work out in the end.” Then, too, it may be difficult for married couples to calculate whether or not relationships are fair and rewarding. (They may settle for a rough and ready definition of “fair outcomes.”) Only the most egregious injustices will be noticed.

Margaret Clark argues that people participate in two kinds of relationships—exchange relationships and communal relationships—and that social norms differ markedly in these relationships. In casual acquaintance or business relationships, exchange norms prevail. People need not feel special responsibility for the other’s welfare. They may invest ideas, time, and money, but with the expectation of receiving their fair share in return. In close, committed, intimate relationships, on the other hand, communal norms prevail. Ideally, men and women are committed to the other’s welfare. They wish to please their partners, to care for and nurture their partners, and to reject such crass considerations as “score-keeping” or a concern with *quid pro quo*. Such differences suggest that couples in close, intimate relationships will be less concerned about day-to-day rewards, costs, and equity than they would be in more casual friendships and work relationships.

Yet, in the end, reward (and costs) and equity do seem to matter in even the closest of relationships. This is the case for most couples—be they single, living together, or married; affluent or poor; married for a few weeks or for a half-century or more. As we have said, people are generally far more concerned with how rewarding their

relationships are than with how fair and equitable they are. Yet, in all of these groups, the degree of reward, fairness, and equity have been found to be linked to marital happiness, contentment, satisfaction, sexual satisfaction, and marital stability. Couples in fair and equitable relationships are also less likely to risk extramarital affairs than are their underbenefited peers and are more confident that their marriages will last. Their relationships actually *are* longer lasting than are those of couples who feel less fairly treated.

In recent years, social scientists have begun to explore the perceptions of women and men regarding who does the most household work (such as preparing meals, shopping for groceries, cleaning the house, caring for children, and caring for needy or elderly relatives). They have also investigated the impact of “fair” or “unfair” divisions of labor on marital satisfaction and stability. Scholars find that for many couples, perceived fairness (in the division of housework) has a positive impact on psychological well-being and relationship happiness and stability. When there is perceived unfairness, the opposite is also true.

Endings

Scholars agree that perceived unfairness and misery are linked. They disagree, however, about the nature of the causal relationship: Does perceived injustice cause dissatisfaction or is the causal order reversed? Equity theorists point out that men and women who are unfairly treated for a prolonged period will begin to wonder: “Does my partner love me? If so, why would he (she) treat me so unfairly?” They begin to ask, “What’s in it for me?” and “Am I getting all I deserve in this relationship?” Clark takes the opposite view: She argues that in communal relationships, couples do not “keep score”; they simply do not think in terms of reward and justice. Thus, if couples *are* concerned with such issues, it is a sure sign that their marriages are in trouble. Misery, then, is the *cause*, rather than the consequence of perceived injustice. All would agree that when men and women are at the point of separation or divorce, they sometimes become consumed with issues of fairness and equity.

In a yearlong longitudinal study, Nico Van Yperen and Bram Buunk set out to answer this question. They interviewed Dutch couples who had

been married for various lengths of time. At Time 1, those who rated their marriages as inequitable were more dissatisfied than their peers. By Time 2 (a year later), these inequitable relationships were often faltering. Thus, the researchers concluded that inequity leads to relationship dissatisfaction and dissolution—rather than the reverse.

It is possible that in failing marriages appraisal might lead to loss of commitment, separation, and then reappraisal . . . the two spiraling down together. In any case, when marriages end, people often become preoccupied with the pain and marital injustices they have endured.

In recent times, scientists have continued to explore the impact of perceived equity on men and women's marital happiness and stability. It appears that although the concern with fairness may wax and wane during a marriage, such concerns always remain there, sometimes just beneath the surface, guiding people's perceptions, happiness, and marital choices.

EQUIVOCATION

Equivocation is communication that is ambiguous, indirect, contradictory, or evasive. One dramatic example has come down through the centuries: In 1170, at the height of a dispute with Archbishop Thomas à Becket, King Henry II exclaimed, “Who will rid me of this meddlesome priest?” Then, when four of his knights murdered Becket, Henry denied responsibility. The king's question has remained equivocal to this day. Was it simply a cry of frustration? A deadly serious request for an assassination? Or a skillful hint to his followers to solve his political problem while providing him with deniability? This entry describes how equivocation occurs frequently in everyday life as a result of situations that make direct communication undesirable.

The more ordinary examples of equivocation occur in virtually every kind of relationship. Imagine that a colleague makes a poor presentation and then asks you how you thought it was. You might say “Not bad!” or “It's much better than I would have done.” Both are equivocal because they do not express a clear opinion. Your colleague will probably infer that the presentation was poor, but you would have avoided saying that directly. It is important to point out that equivocation is not the same as lying, which actively misrepresents information. Janet Bavelas and her colleagues have shown empirically that equivocal messages present information indirectly but do not misrepresent it. Instead, equivocation is closely related to other forms of indirect speech, such as polite requests (e.g., we understand “Do you have a watch?” to mean “Tell me the time”).

The Bavelas group proposed a situational theory in which equivocation is not an attempt to lie, an inability to communicate clearly, or any other inadequacy of the speaker. When a situational dilemma drastically restricts the direct communicative options available, equivocation is a skillful solution. These situational dilemmas include the previous example, which presents a choice between lying (“It was good”) or a hurtful truth (“It was poor”). Lying is a bad option, whether for ethical reasons or concern about being caught. The brutal truth is not good either, because it would hurt the other person and your relationship. Ronny Turner

and his colleagues pointed out that telling a hurtful truth to someone you care about is a relationship lie; it implies that you do not care about that person's feelings or about your relationship, which is not true. It is preferable to avoid both of these options, and most people spontaneously and creatively use equivocation to do so. Equivocation avoids lying but also avoids or at least buffers the hurt by being indirect.

The technical term for any situation that presents competing bad alternatives is an *avoidance-avoidance conflict*. There are many common metaphors for these dilemmas, such as between "a rock and a hard place" or "the frying pan and the fire." Equivocation arises in communicative avoidance-avoidance conflicts, where all direct messages would lead to bad consequences. In such dilemmas, equivocation is a good solution to a bad situation.

Bavelas and colleagues stressed that avoidance-avoidance conflicts are a diverse class of situations with many different specific forms. One familiar subset is the conflict between lying and hurting someone (e.g., having to comment on the colleague's poor presentation, an unsuitable gift, or a friend's awful haircut). Another subset of avoidance-avoidance conflicts occurs when two relationships make conflicting demands (e.g., two friends or neighbors who disagree with each other, a club or organization divided on an important issue, an employer whose demands are not good for the customers). In yet another subset, the truth would harm one's own self-interest (e.g., telling a superior about a bad or embarrassing mistake, losing face by telling the truth, or lying in an election). These are only a few of the often unique relationship dilemmas that can lead to equivocation. A program of laboratory experiments by Bavelas and her colleagues strongly confirmed that a wide variety of communicative dilemmas consistently elicit equivocation. The researchers concluded that the necessary and sufficient antecedent of equivocation is a communicative avoidance-avoidance conflict. Other researchers have applied the theory both in and outside the lab (e.g., with British or Japanese politicians).

The Bavelas group has also studied equivocation outside the lab. The first study examined formal trial judgments, in which judges must write a summary of events that are often repugnant or offensive, such as sexual offenses. As a matter of duty,

the judge cannot avoid these descriptions, yet the graphic details are incongruent with the formal and dignified legal setting. A close examination of the language of trial judgments revealed that judges were significantly more likely to use passive voice, replace verbs with nouns, or omit the agent of the crime when describing the crime than when they were describing neutral or positive parts of the same judgment. For example, one judge wrote, "He [the abuser] feels great remorse for the offense." The positive part was in active voice with the convicted individual as agent ("he feels"), but the negative part became just "the offense," instead of "the rape he committed." Similarly, when Canadian churches chose to apologize for their historic treatment of native people, they used indirect grammatical structures when describing actions that carried legal liability; for example, they consistently referred to "individuals who were abused," without mentioning who abused them. Such "non-apologies" also occur frequently in personal relationships.

A third study used a role-played medical interview in which experienced physicians delivered bad or good news to volunteers acting as patients. The bad-news dilemma is one of the hardest that a physician faces: being honest without crushing the patient. These skillful physicians used more indirect language when delivering bad news, while still remaining truthful. For example, they would say the news was "not great" instead of "bad" and the cancer was "in *the* liver" rather than "in *your* liver."

Is equivocation good or bad? These studies and examples show that evaluative judgments depend on the particulars of the situation. For example, using equivocation to be kind is desirable; being evasive to avoid responsibility is not. Like equivocation itself, it all depends on the situation.

ETHICAL ISSUES IN RELATIONSHIP RESEARCH

To advance the human sciences, researchers invariably need human subjects or participants. However, a balance must exist between the rewards in knowledge gained from the research and the potential costs to the research participants. To minimize these costs, researchers must attend to ethical issues related to research using human beings. This has not always been the case, however; only in the last 60 years has there been an ongoing commitment by researchers using human beings to treat their participants ethically. And the burgeoning interest in scientific research on human relationships brings new ethical challenges. This entry describes the history of ethics in human research, identifies the fundamental principles that guide research involving human participants, and discusses some specific ethical issues of which relationship researchers need to be particularly aware.

Several specific historical events, involving both human medical research and social science research have led to the more ethical treatment of human subjects. The Nazi medical experiments involved research by German doctors on concentration camp prisoners during World War II that was so extreme and detrimental to the participants that the experiments were depicted as crimes against humanity at the Nuremberg Military Tribunals. Subjects in the Tuskegee Syphilis Study, the Jewish Chronic Disease Hospital Study, and the Willowbrook Study were either infected with disease or denied treatment, all with detrimental effects on their health. The Stanford Prison Experiment and the Obedience to Authority Studies were psychological science research examining authority issues. In both studies, the participants were placed in situations involving behaviors that led, for some, to extreme emotional distress during the experiment, as well as to long-term trauma.

As a result of these and other studies, changes occurred in the way in which human experimentation could proceed. In 1979, the Belmont Report, written by a commission established by the U.S. Congress, established three basic ethical research principles: (1) autonomy/respect (people have the right to decide whether to participate in a study as well as to withdraw without penalty), (2) beneficence (participants should understand the risks of participation and any harm should be minimized), and (3) justice (people will not be unfairly singled out to participate because of race, sex, age, or other factors without good reason). To successfully address these principles, researchers also needed to (a) receive informed consent, (b) conduct risk-benefit assessment, and (c) establish fair procedures in the selection of research subjects. Following the Belmont Report, the American Psychological Association provided specific ethical principles and codes of conduct for psychological experiments, including how to plan research, the responsibility of the experimenter, compliance with laws and standards, informed consent, the proper use of deception in research, minimizing invasiveness, and providing participants with information about the study. As such, most, if not all, colleges and universities currently have institutional review boards that provide guidance, as well as approval, for all research involving human subjects.

Ensuring ethics in relationship research poses particular challenges because of the difference between studying human relationships and studying human beings. For example, relationship research, by its very nature, involves studying multiple persons rather than single individuals; as such, the relational system must be taken into account. As defined by the Belmont Report, however, it is individuals who are treated as autonomous agents and who give their informed consent to participate. The principle of autonomy and respect and the requirement of informed consent become problematic when one is studying families, couples, or friendships rather than single persons. For example, when doing research on family relationships, how does one protect the autonomy, and respect the privacy, of persons not involved in the research (e.g., family members, spouses, or friends) about whom participants might disclose to the researcher sensitive or damaging information? Similarly, because the relationship itself is of

interest, how does one negate, or account for, the impact that any one person participating in the research might have on the overall family or marriage? It is not just the benefits and costs of the individual that must be weighed in a risk-benefit assessment, but the impact of the research on other people involved in the relationship, whether or not they are research participants.

The actions of people within relationships also pose unique ethical challenges. Their behaviors do not exist in a vacuum; rather, they exist within the context of the relationships in which the individuals reside. According to the principle of beneficence, research participants should be protected from harm, treated in an ethical manner, and have their decisions respected. How, therefore, does the principle of beneficence protect a spouse, family member, or friend when something is revealed during the research by the other spouse, another family member, or friend? Similarly, how is the marriage protected (or respected) if couple issues arise during the context of the study that might affect the relationship itself?

Ethical issues can also extend to the researcher in relationship studies. For example, what decision does the researcher make if problematic, if not illegal, behaviors such as child abuse or domestic violence are encountered or discovered during the research? In such cases, there may be conflicts regarding issues of confidentiality with issues of safety. In addition, the researcher may need to be aware of laws or regulations regarding whether such information should be reported. In many states, for example, clinicians are required to report suspected child abuse, but this obligation may not apply to researchers.

Finally, researchers grapple with ethics when designing research. For example, studies of marital or family interventions designed to promote positive relationship development require both a treatment group, those that participate in the intervention, and a control group, those that do not. This research design is necessary to measure the effect of the intervention and consequently requires that one group does not receive the potentially beneficial intervention. Employing ethical participant selection strategies can ensure that every participant has an equal chance of being assigned to either the treatment or control group and thus evenly distributes the chance of potential risks and

benefits. In addition, careful monitoring of the study results enables researchers to document intervention benefits and risks and make timely, informed decisions about when to halt the intervention if the results actually indicate a decline in relationship outcomes, or offer the intervention to those in the control group if the intervention is shown to significantly enhance relationships.

These are but some of the ethical issues that the new world of relationship research struggles with. When one moves from the study of individuals to the study of relationships, the boundaries of what can be understood about human beings is greatly extended. However, with this movement into relationship research, different ethical issues must also be considered for the individuals involved and for the greater relationship of which they are a part.

EVOLUTIONARY PERSPECTIVES ON WOMEN'S ROMANTIC INTERESTS

"I should say that the majority of women (happily for them) are not very much troubled with sexual feeling of any kind." So concluded William Acton, a physician of Victorian England, in *Functions and Disorders of the Reproductive Organs in*

Youth, in Adult Age, and in Advanced Life, which appeared in eight editions in the 19th century. Two years after Acton's first edition was published, in 1859, Charles Darwin's *Origin of Species* appeared. A dozen years later, in 1871, Darwin authored *The Descent of Man*. In the latter, Darwin elaborated his theory of evolution driven by female choice, as pushed along by female sexual preferences. Aside from a few notable exceptions, this idea was largely ignored by evolutionary biologists for the century that followed. Robert Trivers's highly influential paper of 1971 revived interest in it. Currently, this concept of "sexual selection" is widely regarded as one of the most important forces giving rise to evolution and, hence, one of the fundamental subjects within evolutionary biology.

More particularly, female "sexual feeling"—patterns of sexual interest, preference, and motivation—is considered central to an understanding of the social nature of a species. Specifically with respect to human sexuality, evolutionary biologists and psychologists have documented a variety of patterns of women's sexual interests and preferences. Though much more work is needed, the field now offers an outline of what selective pressures shaped these patterns as well as the impact of these patterns on broader relationship phenomena. Perhaps not surprisingly, the idea that humans have evolved as a pair-bonding species in which males and females cooperatively care for offspring (though not without conflicts between them) has been a central thesis. Views about how a history of pair-bonding and care of offspring by two parents (rather than almost exclusively mothers, as is characteristic of most species of mammals) is revealed by patterns of female romantic interests, however, have varied across time. This entry discusses evolutionary perspectives on women's romantic interests, their historical roots, and their current status.

The Search for Women's Estrus

From a historical perspective, evolutionary perspectives of women's sexual and romantic interests arose in three distinguishable waves of theory and research. The first began in the late 1800s, when reproductive biology became a serious scientific field. A key concept introduced at that time

was *estrus*. Estrus was defined as a period of relatively intense mammalian female sexual motivation as well as attractivity to males. It is largely confined to a phase of female reproductive cycles around the time of ovulation, when females are fertile (that is, when sex can potentially lead to conception and, ultimately, birth of an offspring). The term derives from the Greek word for *botfly*. When botflies lay eggs on the hides of cows, cows become excited and, accordingly, even in classical times Greeks used the term for botflies to describe a frenzied state. Reproductive biologists co-opted the term to refer to the frenzied state of a fertile mammalian female (also referred to as "heat").

In the 1920s, reproductive biologists began discovering hormones that play important roles in the regulation of reproductive function, the first of which was estrogen. In most all mammalian females, estrogen levels peak just before ovulation, and, indeed, this rise plays key roles in orchestrating changes in reproductive physiology that, for a few days of the reproductive cycle, permit conception. The name *estrogen* was derived from the term *estrus*: Estrogen is purportedly the "gen" or generator of estrus. (Other reproductive hormones, notably progesterone and testosterone, play important roles as well.)

Women possess estrogen and, just like most other mammalian females, their estrogen levels surge just before ovulation. When reproductive biologists discovered estrogen, then, it made sense to look for evidence of estrus in women. Beginning in the 1930s, many studies looked for evidence that women exhibit marked sexual desire (as well as greater attractivity to men) when fertile in their cycles. Though evidence has been mixed, researchers have not found consistent evidence of these changes across women's cycles. For instance, in a 2005 study, Alexandra Brewis and Mary Meyer analyzed reports of recent sex intercourse with a primary partner provided by about 20,000 normally ovulating women in 13 developing countries. No evidence was found that the frequency with which women have sex with their primary partners changes across the cycle, aside from a drop during menses. Although this study is limited because intercourse is hardly a straightforward measure of sexual desire, studies using other measures (self-reported desire, female-initiated intercourse) have yielded mixed results as well.

Even by about 1960, then, a number of scholars concluded that, evolutionarily, women had “lost” estrus—any marked changes in sexual or romantic interests across the cycle. It was replaced by continuous sexual receptivity across the cycle. As women’s hormones change in ways similar to other primate species, this conclusion was tantamount to the claim that hormonal control of women’s sexual and romantic interests had, over the course of human evolution, been relaxed.

The Search for Why Women “Lost” Estrus

This conclusion having been drawn, a second wave of scientific investigation into women’s sexuality attempted to address the question of *why* women had lost estrus. What selective forces led to the disappearance, in humans, of marked female sexual motivation and attractivity to males during the fertile phase of women’s cycles? By the late 1970s, this question became a salient one for scholars interested in understanding the unique social nature of the human species. Indeed, in 1979 alone, at least four major papers proposing answers to this question appeared (though the answers offered by these papers are but a subset of all that have been offered).

One particularly prominent and influential view was offered, separately by Donald Symons and by Richard Alexander and Elizabeth Noonan. It proposed that loss of estrus and the purportedly crucial feature that resulted, the concealment of ovulation (lack of signs of ovulation evident to either females themselves or to observers), played an important role leading to pair-bonding in humans. As long as a male can discriminate females who are fertile from those who are infertile in their cycles, it may benefit him to attend particularly to those who are fertile—that is, to those females who are able to conceive an offspring at that point in time. If a male cannot discriminate fertile from infertile females, however, it may benefit him to attend particularly to one female whose offspring he has high probability of having sired, particularly if the assistance he offers to care for those offspring can substantively contribute to their well-being and fitness. Loss of estrus and concealed ovulation, in this view, was not the sole reason why human males invest in offspring and why males and females pair-bond. But in the

context of other factors facilitating biparental care (care of offspring by both parents) in humans, loss of estrus and concealed ovulation arose in females as tactics to enhance the care that their offspring received from putative fathers.

One contrasting theory was proposed by Lee Benshoof and Randy Thornhill (and mentioned by Symons as well). They argued that loss of estrus and concealed ovulation evolved after pair-bonding in humans had already arisen. Rather than functioning to facilitate pair-bonding, concealed ovulation in this view functioned to facilitate female choice of sires of their offspring. Sometimes, it may not pay a female (in the currency of her evolutionary fitness) to have her offspring fathered by her primary mate. Rather, for a variety of reasons (better genes, genes more compatible with hers, other material advantages), it may be best for her to choose a sire of her offspring other than her primary partner. By hiding the period she is fertile and can potentially conceive, concealed ovulation, in this view, interferes with the ability of her partner to prevent “extra-pair copulation” (sex with a partner other than a primary partner in a pair-bonding species) through “mate-guarding” and thereby fosters female sire choice.

No one theory of concealed ovulation clearly won out over all competitors through the 1980s and 1990s. Much research during this period, however, did provide evidence for the importance of pair-bonding in shaping human mating and romantic preferences.

Women’s Estrus Found?

The third phase of research speaking to the evolution of women’s sexuality began in the mid-1990s. Though it didn’t begin with this intention, viewed in retrospect a major thrust of this most recent phase has been to question the conclusion reached almost half a century ago, that women have lost estrus. A wealth of research now indicates that women’s sexual interests and motivations do systematically change across their cycles. When fertile in their cycles, normally ovulating women particularly prefer a variety of masculine male traits perceived through multiple sensory modalities (e.g., men whose scent is associated with social dominance, facially masculine men, men whose bodies are masculine, masculine vocal qualities,

masculine behavioral displays, relatively tall men). As well, women prefer traits associated with body symmetry (an indicator of developmental instability), more so when fertile than when infertile in their cycles (e.g., scents associated with symmetry, facial features associated with body symmetry). Masculine traits and traits associated with symmetry may have been indicators, in harsh ancestral environments, that males could pass onto offspring genes that would promote fitness and success. Women don't particularly prefer all positive male features when fertile (e.g., those particularly favored in long-term mates, such as kindness or faithfulness, are not particularly preferred then). And even with respect to traits women do prefer more when fertile, they only find these traits more sexually attractive; women do not rate these traits as being particularly attractive in their long-term mates.

Although the evidence that women's preferences do shift across their cycles is now compelling, it is worth noting that women may not be conscious of these preference shifts. The methodology used in these studies has not typically asked women to report how much they desire or prefer various partner qualities in mate. Rather, women in these studies typically have been asked to rate a series of men who differ on various qualities (as manipulated by researchers, or as a function of variation in representative samples of men). By examining how male features predict women's stated attraction to men (their sexual attraction or their attraction to men as long-term mates), researchers infer the features that women find particularly attractive, and then compare the inferred preferences across phases of women's cycles. It is quite possible that most women are not aware of how their preferences, as assessed in these studies, vary across their cycles.

One interpretation of this evidence is that estrus was never lost during women's evolution, and that women's sexual motivations and interests have never become fully divorced from hormonal influence. Rather, women retain a distinctive phase of sexual interests and pattern of attraction when fertile in their cycles, one influenced by hormones such as estrogen. This phase may have been modified during human evolution. For instance, overt signs of women's fertile phase appear to have become suppressed during human evolution, even if not fully eliminated and even if women do retain

distinct patterns of interest when fertile. "Concealed estrus"—a lack of overt signs of women's estrus to observers—may have been selected in the context of pair-bonding, along lines similar to earlier theories of concealed ovulation. In particular, concealed estrus may have permitted ancestral women to maintain support from pair-bond partners while increasing their latitude for choosing sires for offspring. Moreover, women may have evolved a phase of "extended sexuality"—sexual receptivity and interests outside of the fertile phase—in combination with estrus. The primary benefits that may have led this sexuality across the cycle purportedly would have been derived through pair-bonding, which it could have promoted along lines suggested by Symons, Alexander, and Noonan (albeit regarding concealed ovulation rather than extended sexuality per se).

In this view, features of women's sexual motivations and their changes across the cycle constitute telltale signs of ancestral selection pressures that forged patterns of human mating. In particular, patterns do contain signatures of humans having evolved as a pair-bonded species. At the same time, however, they also reveal that conflicts of interest between male and female pair-bonded partners (e.g., those surrounding sexual fidelity to the relationship) have played a hand in shaping female sexuality as well.

It should nonetheless be emphasized that these recent views of female estrus, though garnering a good deal of empirical support, have not been fully vetted by a scientific process. Current views of the evolution of women's sexuality markedly differ from dominant views of half a century ago. Quite possibly, future generations of scholars will view current interpretations of the extant literature as incomplete or flawed in important ways.

EVOLUTIONARY PSYCHOLOGY AND HUMAN RELATIONSHIPS

An evolutionary approach to human relationships presumes that interactions between parents, children, siblings, friends, lovers, and enemies are better understood by viewing them within the perspective of comparative biology. On the one hand, the approach assumes deep commonalities among social behaviors of animal species ranging from ants and bees to chimpanzees and human beings. On the other hand, the approach makes important distinctions—presuming that there might be unique features characterizing human relationships, and that different types of human relationships might operate according to different functional rules. This entry includes a brief summary of several basic ideas connecting evolutionary biology and psychology and a review of some research applying those ideas to human relationships.

What Is Evolutionary Psychology?

Evolutionary psychology is the study of behavior, thought, and feeling through the lens of evolutionary biology. Modern evolutionary psychology is a synthesis of developments in several fields, including zoology, ecology, cognitive neuroscience, anthropology, and social psychology. Central to this synthesis is Charles Darwin's theory of evolution by natural selection. Following Darwin, evolutionary psychologists presume that human behaviors reflect the influence of physical and psychological predispositions that helped our ancestors survive and reproduce.

The first question an evolutionary theorist asks about any feature of a living organism is this: What is its adaptive function? How does this feature help the organism survive and, more importantly,

reproduce? Why do hawks, but not moles, have excellent vision? Why do peacocks, but not peahens, have bright feathers? Evolutionary psychologists examining human relationships consider the functional implications of human evolutionary history (e.g., living in omnivorous hierarchical primate groups populated by kin) for relationships with friends, lovers, enemies, and kin. Although we humans may take romantic relationships, friendships, and status hierarchies for granted, many of our mammalian relatives never concern themselves with the questions that often consume our days. As discussed later, the adaptive function of a particular feature can take different forms depending whether the human being in question is a male or a female, young or old, and currently mated or not.

Domain-Specific Mechanisms

People must make important decisions within several different domains—some are nonsocial (what to eat, how to keep warm, for example); others are social (who to trust as a friend, whom to make a romantic overture toward, etc.). A key assumption of an evolutionary approach is that different problems cannot be solved using one single-domain general rule. Although it is generally true to say that people interact with others to get rewards, or to maximize benefits and minimize costs, such explanations fail to explain why and when some things are pleasant and others are unpleasant. A kiss may be a reward or a punishment, depending on who is kissing whom (a lover vs. a panhandler, for instance). Likewise, winning a competition may feel bad or good, depending on who is being beaten (one's 5-year-old daughter vs. an arrogant coworker, for example). From an evolutionary perspective, different relationships are assumed to be controlled by different psychological mechanisms, each characterized by different decision rules.

This assumption is supported by a broad literature suggesting that animal's brains are composed of a number of specialized "modular" mechanisms. For example, birds use different memory systems and different rules for remembering song, tastes of poisonous food, and locations of food caches. Likewise, humans inherit different memory

systems for dealing with different, sometimes conceptually incompatible tasks, including learning language, learning to avoid poisonous foods, and remembering other people's faces. Researchers interested in human relationships have begun to apply the concept of domain specificity to understanding the differences between friendships, status hierarchies, family relationships, and short- and long-term romantic relationships, all of which seem to operate according to slightly different rules.

Life History, Parental Investment, and Sexual Selection

Studying the array of unique adaptations found across the animal kingdom has uncovered several general principles governing the evolution of diverse traits. One powerful set of principles is embodied in *life history theory*—which assumes all organisms must resolve a key set of trade-offs throughout their lives. Central trade-offs involve allocating energy to development versus mating versus parenting (effort spent on attracting mates is effort that cannot be spent on caring for young, for example). Depending on ecological factors, different animals allocate effort differently across their life spans. Some fish, for instance, change from small drab females into large colorful males if a territory becomes available. Some small mammals start reproducing weeks after they are born, others wait decades. Some animals (such as salmon) reproduce in a single grand effort; others (such as elephants) reproduce repeatedly over their life spans. Human life history involves a long period of somatic development, earlier sexual maturity in females than in males, and more life-span mating effort by males than by females.

Why do females and males within species often have different life histories? Part of the answer has to do with *differential parental investment*—which usually involves greater amounts of offspring care by females. In mammals, for example, females carry the young inside their bodies and nurse them after they are born. Within a species, the sex investing less in offspring tends to compete for mating opportunities with the higher-investing sex. Because mammalian females always pay a high price for reproduction, whereas males may contribute little or nothing to offspring care, females

are relatively more selective in their choice of mates. This is linked to *sexual selection*—which refers to the relative success of traits that assist in mating (by helping either to attract the opposite sex or to compete with one's own sex). Darwin developed the idea of sexual selection to address the fact that one sex is often larger, more colorful, and more competitive than the other. A peacock's bright feathers increase his chances of attracting peahens as mates. Ostentatious feathers are found in males and not females because the females make a higher investment in the offspring and are therefore choosier about their mating partners (who must consequently compete to be chosen).

Evolutionary History and Human Relationships

For most of human evolution, our ancestors lived in groups of less than a hundred people who were typically related to one another. Thus, human cognitive mechanisms were designed not for life on the freeways and malls of modern Los Angeles, but for coexistence in small hunter-gatherer groups. Because hunter-gatherers everywhere faced some similar problems and opportunities, evolutionary theorists expect to find a number of human universals beneath the surface diversity of modern cultures. Evolutionary psychologists consider some of the functions relationships might have served in these ancestral human groups, focusing on six domains of social interaction: affiliation, status, self-protection, mate search, mate retention, and kin care. Each domain is characterized by different problems and opportunities, and each is likely to operate according to slightly different arrays of decision biases.

Affiliation

Research on hunter-gatherers suggests that social alliances may have been critical to our ancestors' survival and reproduction. Anthropologists studying modern hunter-gatherers, such as the Aché of South America, find that the likelihood of capturing game is often quite low on any given occasion for any given individual. If one individual catches a large fish or a deer, however, it is too much to consume alone and will rot if not shared. By sharing, individuals help other

members of the group survive, and accrue credit for the future when their own luck is down. Furthermore, people in cooperative networks can accomplish tasks none of them could easily do alone (such as hunting large game).

There are costs as well as benefits to alliances: It takes time and resources to help other people, and those people might want to take more than they give in return. Group members also compete with one another for food, status, or mates. How much to cooperate, and with whom, is influenced by two powerful evolutionary principles—*inclusive fitness* and *reciprocity*.

Inclusive fitness refers roughly to an organism's success in getting its genes into future generations. The term *inclusive* refers to the fact that fitness is measured not simply by the number of offspring an organism produces, but also by contributing to the success of relatives. Hence, all living organisms, including humans, are expected to cooperate more readily with close relatives. In hunter-gatherer societies, individuals tended to be closely related, and even in modern societies, people spend most of their lives in close contact with kin.

Human beings are also cooperative and generous with people who are not related to them. *Reciprocity* involves kindness toward nonrelatives whom one expects to be beneficial to oneself in the future. Unlike relationships with kin, people are more sensitive to violations of reciprocity when unrelated individuals are involved. Indeed, research by Leda Cosmides and John Tooby has demonstrated that people are exquisitely sensitive to other people's violations of social contracts, to the extent of being able to solve difficult logical problems if those problems are framed as involving potential cheating. Evolutionary psychologists assume that this sensitivity to reciprocity is at least partly innate because it helped our ancestors survive and reproduce.

Status

Human beings everywhere, like many but not all mammalian species, arrange themselves into status hierarchies. There are costs associated with achieving status, but high status individuals, both men and women, are typically compensated with greater access to resources. For males, there are additional benefits to gaining status because

females are more likely to mate with higher status males. In line with our earlier discussion of parental investment and sexual selection, females may place relatively more value on status for two reasons: (1) high status men can acquire more of the indirect resources males provide for their offspring, and (2) high status males have demonstrated their relative superiority over other males. Consistently, men around the world are more likely to compete for status, sometimes violently. Such competition is most pronounced among young unmated males and tends to diminish once a male gains social position and a mate.

Self-Protection

Ancestral humans frequently confronted dangers from members of other groups and occasionally from members of their own groups. A number of cognitive biases suggest that people are especially alert to possible threats from others. Males posed, and continue to pose, greater threats of physical violence. Consistently, people are especially rapid at detecting angry facial expressions on men's, as opposed to women's, faces. People are also biased to perceive intentions of threat more readily in members of outgroups, and surprisingly good at remembering angry males from threatening outgroups. Consistent with the fact that our ancestors were more defenseless in the dark, research by Mark Schaller and his colleagues has demonstrated that ambient darkness increases threat-related prejudices against stereotypically dangerous groups. When feeling threatened, people are more likely to band together with ingroup members. Thus, conditions that were relevant in the ancestral past continue to influence relationships with strangers in the modern world.

Mate Search

Differential reproduction is the central driving force of evolution. We are here today because our ancestors were successful at mating. For most mammals, courtship mostly involves males competing for the attention of females. This is because mammalian males usually contribute little beyond sperm to their offspring, making female parental investment (and consequent choosiness) much higher. Humans are mammals, which means

(a) women are physiologically equipped to raise offspring without help from men, and (b) men could, conversely, father offspring with no investment beyond sperm. Unlike most mammals, however, human offspring are born helpless and require more than the usual amount of parental care. In species with helpless young (such as most birds), a common pattern is for males to contribute to offspring care. Although there are many instances of human females raising offspring without male help (the typical mammalian pattern), more common across human cultures is some degree of paternal investment in the offspring.

When males contribute to offspring, they tend to become more selective in choosing mates. Human beings adopt different mating strategies that seem to be sensitive to levels of parental investment. For casual sexual relationships, males are relatively unselective about mating, whereas females favor especially symmetrical and healthy males. For longer-term monogamous relationships, in which men make a high investment, men become more similar to women in being relatively more selective about their mates. Nevertheless, because mothers and fathers contribute different resources to the offspring, each sex seeks slightly different characteristics in a mate. Men seek traits that have been associated with fertility (such as relative youthfulness and low waist-to-hip ratios). Women, on the other hand, are attracted to men demonstrating dominance and social status. Because both men and women contribute heavily to their offspring, both sexes are choosy about long-term relationships and prefer their mate to possess as many good qualities as possible (e.g., attractiveness, high status, kindness, friendliness). Hence, although there are still sex differences in mate selection criteria, men and women differ much less in relative choosiness for long-term relationships.

Mate Retention

Keeping mates involves a different set of challenges and opportunities than does choosing them. Both sexes are expected to be alert to other members of their own sex who might disrupt their relationships. Women are attentive to other women who are highly attractive, men to other men who are socially dominant. Because fertilization occurs inside the female's body, mothers are always

certain their children are their own, whereas men risk investing resources in other men's offspring. Women are at risk for losing their partner's investment of resources and ought to be relatively more concerned that interloping females might establish a long-term relationship with their partners. Consistently, research by David Buss and others has demonstrated that women are, compared with men, more jealous of their partners' deep affectionate relationships with other women and relatively less jealous about casual sexual contacts. These sex differences are relative rather than absolute—neither sex welcomes either sex or love between their partners and others. Again, because both sexes invest heavily in long-term relationships, both have much to lose if their partners form romantic bonds with others.

Kin Care

Following principles of inclusive fitness, one expects to find relatively less tit-for-tat exchange and more communal sharing of benefits among close relatives. People are indeed more willing to help others with whom they share genes, and research by Eugene Burnstein and his colleagues found that such aid takes into account their relatives' reproductive potential. Whereas a 40-year-old woman is equally related to her 17-year-old daughter and her 70-year-old mother, she would be expected to invest more resources in her daughter (whose reproductive potential is high) than in her elderly mother (who, though capable of providing indirect benefits of grandmothering, has no direct reproductive potential remaining). A study by Simon Laham and colleagues examined the impact of such considerations on grandparental effort, finding relatively more investment by mother's mothers, for whom there are no uncertain paternal links involved. On the other hand, investments in sons' children were relatively high if a grandmother did not have (more certain) grandchildren via a daughter.

Conclusion

Several decades ago, an evolutionary perspective on human social behavior was considered quite controversial. In the intervening years, the perspective

has generated a number of insights about human relationships and many novel research findings. Because the perspective is still relatively new, many implications remain to be identified and tested. There has been much more research on sex differences related to mate selection than on other types of relationships, for instance. The perspective can provide a number of insights about human relationships. It highlights connections that are not otherwise obvious, for example, how competition for status within one sex is connected to romantic relationships. The perspective can also help clarify distinctions by focusing on different functional constraints on relationships between friends, mates, and family members and between men and women. A more broadly appealing feature of the evolutionary perspective is its interdisciplinary nature, connecting research on human behavior in Western societies with cross-cultural findings from anthropology and biological findings about other species. The approach has also contributed to, and been informed by, new developments in economics and cognitive neuroscience. As these fields continue to exchange information, we can look forward to new discoveries, and to novel and more complete theoretical insights.

EXCHANGE ORIENTATION

Exchange orientation, as originally defined by Bernard Murstein, refers to the tendency to believe that one's relationships with others should be governed by a principle of reciprocity such that favors and gifts should be exchanged equally among the parties involved in those relationships. That is, when one person in a relationship receives a gift or favor from the other, he or she should repay that person with an approximately equivalent gift or favor. Moreover, when one party in a relationship incurs a cost related to the relationship, the

other party should incur a similar cost. One implication of holding an exchange orientation in one's relationships is that a person experiences discomfort when he or she is unable to reciprocate and feels let down when another person fails to reciprocate. The concept of exchange orientation has important implications for human relationships of all types—including business partners, friends, and romantic partners. This entry explores different conceptions of exchange orientation, distinguishes it from alternative ways of thinking about allocation of costs and benefits in relationships, explores the correlates of exchange orientation, and concludes with a discussion of the universality of this way of thinking in relationships.

Conceptual Overview

The concept of *distributive justice* refers to the transfer of benefits and costs in relationships and perceptions of that transfer. Exchange orientation is one approach to thinking about distributive justice and, as stated earlier, reflects a tendency to prefer and seek equal allocation of costs and benefits among parties in relationships. More specifically, when Murstein first wrote about exchange orientation, he described a person high in such an orientation as being concerned with making sure that there was a balance among the parties involved in a relationship in costs and benefits. That is, every cost incurred by one person in the relationship should be met with a similar cost for the other party and every benefit gained by one person in the relationship should be reciprocated by the other with a similar benefit.

A natural implication of such an orientation is that a person would be upset whenever an imbalance was present in the relationship, whether he or she believed the self to be overbenefited or underbenefited. He or she would be dissatisfied whenever believing that the self incurred more costs than the other party in a relationship or whenever believing that the self received more benefits than the other. Murstein initially proposed that this orientation would be harmful to marital satisfaction because people generally are more aware of what they do for others than they are of what others do for them. So, all things being equal, people will generally perceive themselves to be underbenefited relative to

others with whom they have relationships. If people generally perceive this to be the case, then it makes sense that a high exchange orientation would be associated with less satisfaction in marital relations. In contrast, he proposed that high exchange orientation would actually be beneficial for relatively new friendships. Because new friendships are comparatively much easier to get out of, people who perceive a great deal of inequity in a friendship would simply leave that relationship.

Murstein found support for these ideas in a study of married couples and college friends. Because exchange orientation is an internal attitude, he assessed this orientation with self-report items such as "If I do dishes three times a week, I expect my spouse to do them three times a week," with which participants indicated their level of agreement. He found that spouses with higher levels of exchange orientation reported lower levels of marital adjustment. In contrast, he found that friends who reported higher levels of exchange orientation reported higher levels of friendship intensity, particularly when paired with a friend who also reported higher exchange orientation. Subsequent research has found a similar pattern of results in marital relationships; however, several studies have, in contrast to Murstein's, found that higher exchange orientation is associated with *less* satisfaction in friendships.

Several years later, Susan Sprecher refined Murstein's initial conceptualization of exchange orientation. More specifically, she introduced the idea that people could be concerned by two different kinds of exchange considerations. First, they could be concerned that they are not receiving as much from a particular partner as they are giving to that partner. She termed this *underbenefiting exchange orientation*. Alternatively, they could be concerned that they are not giving as much to a partner as they are getting from him or her. She termed this *overbenefiting exchange orientation*. These orientations are conceptually quite distinct and do not necessarily overlap. A person could be, for example, high in underbenefiting exchange orientation but low in overbenefiting exchange orientation, or vice versa. Sprecher argued that whereas underbenefiting exchange orientation would be negatively associated with good relationship outcomes, the overbenefiting exchange orientation might actually be associated with *good*

outcomes because it could lead people to behave in especially giving ways. She found evidence consistent with this idea in a study of romantically involved college students. Having a partner high in overbenefiting exchange orientation was associated with more relationship satisfaction, commitment, and love. One's own overbenefiting exchange orientation was generally unassociated with one's own outcomes, however. Moreover, being higher in underbenefiting exchange orientation was associated with worse relationships outcomes. This suggests that the two types of exchange orientation are indeed distinct and that they have different implications for relationships.

Margaret Clark, Judson Mills, and their colleagues have described a different approach to distributive justice in relationships. They have argued that some people have more of a *communal orientation* than an exchange orientation. This means that people are guided not as much by equality of benefit exchange in a relationship as by equality of attention to and responsiveness to needs. That is, provided both partners are equally caring and attentive, it is not problematic for there to be inequity in cost and benefit allocation in a relationship. This is especially true when one party in the relationship has substantially greater needs because of, for example, a disability or financial woes. It is also true when one person is more able to provide to the other such as is typically the case in relationships between parents and young children. The inequity would largely disappear, however, if there was no longer a difference in needs or ability.

Exchange Orientation: A Personality Variable or Relationship Specific?

Both Murstein and Sprecher have discussed exchange orientation as an individual difference or personality variable. That is, they have described people as being chronically higher or lower in exchange orientation. Clark and her colleagues agree with this conception of exchange orientation but also have suggested that some relationships are normatively more exchange in nature. Business relationships and casual acquaintanceships, for example, are much more likely to be characterized by an exchange norm than are close

friendships or romantic relationships. Instead, these latter relationships are more likely to be governed by a communal norm. In support of this idea, Clark has found that individuals actually prefer it when somebody with whom they desire a close relationship or with whom they already have such a relationship *do not* immediately pay them back for a favor. In contrast, people prefer it when a stranger immediately repays them for a favor. Moreover, people believe that an exchange norm is not ideal for close relationships such as marriages and close friendships. Such exchange concerns are more prominent in certain kinds of relationships than in others.

Correlates of Exchange Orientation

Research has established a number of important correlates of exchange orientation. People high in exchange orientation are especially likely to feel lonely. Relatedly, they are more likely to think of themselves as highly individuated such that close others in their lives are not important components of their self-concepts. These findings suggest that people high in exchange orientation perceive more of a barrier between themselves and others.

Research has also indicated numerous implications of exchange orientation for relationships. People high in exchange orientation tend to be less satisfied with and less trusting of spouses and friends. People lower in exchange orientation report greater friendship intensity with others and more satisfaction with friends, spouses, and coworkers. They experience less negative emotion when faced with inequity in their relationships and are less likely to behave in ways that maintain or restore equity of benefit allocation in their relationships.

How Universal Are Beliefs About Exchange in Relationships?

Generally speaking, all societies have norms about how costs and benefits should be distributed in relationships. It has been suggested that exchange norms developed as a function of stable food supplies and trade economies because people needed explicit means of making sure that they were not taking advantage of others or being taken advantage of themselves. In contrast, communal norms

would develop from irregular food supplies. Irregularities in food supplies would lead people to share their bounty with others when they had procured a large supply of food with the expectation that others in their group would do the same for them if situations were reversed. That being said, it appears that people of all cultures have some sensitivity to exchange concerns.

Not all people are equally sensitive to such concerns, however. For instance, people in the United States, a highly individualistic country, tend to be more exchange-oriented than do people in the Netherlands. People from more collectivist cultures tend to be lower in exchange orientation than do people from more individualistic societies. Despite these differences, people from all cultures are sensitive to exchange concerns and there is considerable variability within cultures regarding how exchange-orientated individuals are.

EXCHANGE PROCESSES

Social exchange theory has been used to explain individuals' behavior across a broad range of interpersonal relationships. First proposed by sociologist George Homans in 1958, social exchange theory posits that all interpersonal interactions (e.g., romantic relationships, friendships, job relationships, interactions with strangers) are based on an exchange of goods or resources. This entry discusses the basic principles of social exchange theory, explores several exchange-based theories, and examines the application of exchange principles to sexual behavior.

Exchange Theory

When Homans first proposed that social interactions might be viewed from an exchange perspective, his thinking was influenced by research in economics. He proposed that social interactions are based on an exchange of goods. These goods might be material, for example money, gifts, or material possessions, or more symbolic (e.g., prestige, approval). The motivation for our interactions with others is that those interactions provide us with desired goods (rewards). Others interact with us because we also possess the ability to provide those individuals with rewards. Thus, our social interactions are based on an exchange of rewards with others.

Homans also noted that rewards are also accompanied by costs. Some costs are encountered when we provide others with desirable resources. For example, it is costly to provide others with monetary rewards and takes time to provide another with information.

Another type of cost (opportunity costs) is incurred when individuals are faced with multiple situations that provide opportunities for obtaining rewards. For example, individuals involved in

romantic relationships receive rewards by spending time with their partners. The opportunity cost of doing so, however, is that spending time with their partners prevents them from engaging in rewarding activities with other individuals such as friends or family members.

In applying economic theory to social interactions, Homans proposed that individuals seek to maximize their profit from social interactions, such that $\text{Profit} = \text{Rewards} - \text{Costs}$. It has also been noted that when individuals encounter high costs, they typically expect high rewards in return.

Although the notion of individuals exchanging rewards is, on the surface, a simple one, several points deserve mention. First, rewards are subjective. A good is rewarding only if another individual values it. Many individuals find attention from others to be rewarding but an individual suffering from social anxiety may find that attention aversive. Second, scarce resources tend to be valued more highly than do those that are plentiful. Third, satiation can occur if a reward is received too often. That is, if an individual receives the same reward repeatedly, that reward tends to lose some or all of its value.

To this point, rewards have been discussed in a rather general context. Research by Uriel and Edna Foa, however, suggests that most rewards exchanged in social interactions can be divided into six categories: love, status, information, money, goods, and services. Further, these categories differ along two dimensions. First, some rewards are more concrete whereas others are relatively abstract. Goods and services are generally the most concrete, but love and money are considered to be more abstract. Status and information are the most abstract.

The second dimension concerns how particularistic each reward is. Particularistic refers to the extent to which the source of the reward is important in the exchange. Money is generally the least particularistic. Most individuals value money regardless of its source (with some exceptions—drug money may be one example of money that has little value to many). Information and services are considered to be somewhat more particularistic, followed by status and goods. Love is the most particularistic reward; most individuals are selective regarding from whom they are willing to accept love.

Finally, it has been proposed that these dimensions influence the exchange of resources. As a rule, it is easier to exchange rewards that are more similar to one another. For example, if one individual borrows money from another, the easiest and most acceptable form of restitution is to simply repay the money. Most individuals, however, find the notion of exchanging money for love to be difficult to comprehend.

Exchange-Based Theories

Several important theories of interpersonal relationships are based on social exchange including Equity Theory, the Investment Model, and Margaret Clark's work on communal and exchange relationships. Social exchange has also been proposed as a theoretical explanation for some aspects of gender differences in sexual interactions. Each of these areas will be briefly examined.

Equity Theory

According to Equity Theory, individuals put resources into their relationships (inputs) and in return receive rewards (outcomes) from those relationships. Rather than attempting to maximize their profit (as proposed by Homans), however, other researchers, including J. Stacy Adams and Elaine Hatfield and colleagues, have proposed that individuals value equity in their social exchanges. That is, individuals are concerned with getting what they feel they deserve out of their social relationships. One means that individuals have of determining whether their interactions are equitable is to compare their interactions with those of similar others. For example, an employee concerned about the fairness of her or his salary may attempt to determine the salaries of coworkers. Another means of determining equity, particularly in more intimate relationships, is to compare one's inputs and outcomes obtained in the relationship with the inputs and outcomes of one's partner. That is, is one individual's profit from the relationship greater than, less than, or equal to that of her or his partner? Inequity can occur in two forms. If an individual's outcomes are greater than they should be given the individual's input into that relationship, the individual is being overbenefited.

Essentially, overbenefited individuals are getting more than they should. Adams proposed that individuals may feel guilt for overbenefiting from their relationship, but research also indicates that individuals may find satisfaction in this situation.

The other form of inequity occurs when individuals receive fewer outcomes than they feel they should be given their inputs into the relationship. In this case, they are being underbenefited and are receiving less than they deserve. Those who are underbenefited typically experience anger, frustration, and feelings of being exploited.

Given that individuals value equity, Adams proposed that when faced with inequity, there would be attempts at restoration. This might be done psychologically. Overbenefited individuals may attempt to convince either themselves (or their partners) that they are putting more into the relationship or that they are getting less out of it. Conversely, underbenefited individuals may persuade themselves (or be persuaded by their partners) that they really are not putting that much into the relationship or that they are actually getting a great deal out of it. Essentially, people are often skilled at rationalizing both their own and their partner's behavior.

Another means of restoring equity is to do so behaviorally. On the one hand, if individuals perceive themselves to be underbenefited, they may reduce their inputs into the relationship or try to convince their partners to increase theirs. On the other hand, overbenefited individuals might increase their inputs or encourage their partners to decrease theirs. One interesting aspect to Equity Theory is the recognition that if one member of a dyad alters her or his inputs, this is likely to affect the outcomes of the other member.

A third means of responding to an inequitable relationship is to end the relationship. Rather than exerting time and energy attempting to restore equity an individual may simply choose to simply leave an involvement that is perceived to be unfair. Typically, however, this is a course of action that is taken only after other attempts to restore equity have failed.

The Investment Model

Caryl Rusbult's Investment Model provides another perspective on how social exchanges may

be evaluated. This model predicts that relationship satisfaction is a function of the rewards and costs associated with the relationship. Rusbult proposes that individuals evaluate their relationships by comparing their rewards and costs with their comparison level. The comparison level consists of expectations individuals hold about various types of interpersonal relationships. The comparison level can include, among other things, expectation for benefits anticipated from the relationship, beliefs about how partners should treat one another, and how the relationship should progress. Thus, satisfaction with a romantic relationship depends on whether the rewards and costs of that relationship meet the expectations the individual holds for that relationship. If these relationship outcomes exceed expectations, that relationship should be satisfying, but if those expectations are not met, the relationship would be perceived as unsatisfying. Satisfaction, then, can be summarized mathematically as

$$\text{Satisfaction} = (\text{Rewards} - \text{Costs}) - \text{Comparison Level}$$

The Investment Model also proposes that satisfaction is an important determinant of commitment. Specifically, commitment is proposed to be a function of three factors: satisfaction, investments, and the comparison level for alternatives. This relationship can be expressed as

$$\text{Commitment} = \text{Satisfaction} + \text{Investments} - \text{Comparison Level for Alternatives}$$

As might be expected, greater satisfaction tends to lead to greater commitment to any given relationship. Investments, however, also increase commitment. Investments are resources (i.e., time, money, emotional effort) that are put into the relationship that would be lost if the relationship were to end. Investments tend to increase commitment by increasing the costs of ending the relationship. A third determinant of commitment is the comparison level for alternatives or an evaluation of the attractiveness of the best available alternative to the relationship. The attractiveness of any given alternative is evaluated in the same manner as is satisfaction with the current relationship. Specifically, the attractiveness of an alternative is a function of the rewards and costs of the alternative and the individual's comparison level.

Attractive alternatives tend to weaken commitment, whereas the lack of attractive alternatives serves to strengthen that commitment.

Exchange Versus Communal Relationships

The theories discussed thus far share the common assumption that exchange principles can be used to explain social interactions across a wide range of relationships. Exchange Theory, however, has been criticized for this assumption. Specifically, some researchers have proposed that social interactions in intimate relationships are different than those that take place in other, less intimate involvements. Clark and her colleagues have explored this hypothesis.

Clark's research suggests that many social interactions are governed by social exchange principles, and she refers to these involvements as exchange relationships. In exchange relationships, individuals are motivated to maximize their profits. Rewards are given to others either in return for rewards received in the past or in anticipation of receiving rewards in the future. These exchanges are sometimes referred to as "tit for tat." In exchange relationships, individuals also keep track of the rewards given and received and are concerned that these exchanges remain fair and equitable.

More intimate relationships, referred to as communal relationships, do not seem to be governed by these same exchange principles. In communal relationships, an exchange of rewards still takes place. The motivation for this exchange, though, is not the maximization of profit. Instead, rewards are provided to intimate partners from a desire to please them and to fulfill their needs. Thus, in communal relationships, rewards are given without consideration of rewards received or the expectation of future gain. Instead, individuals monitor their partner's needs and are less attentive to their inputs into the relationship than is the case with exchange relationships. Thus, although communal relationships are still based on exchange principles, the exchange process is different than that which takes place in most other social interactions.

The Social Exchange of Sex

From a social exchange perspective, sexual interactions are no different than other social interactions; they

are also based on an exchange of rewards. In particular, social exchange theory has been proposed as explanation for the finding that men are, on average, much more interested in and supportive of the sex industry (prostitution, pornography) than are women.

An exchange perspective proposes that sex is a female resource. Specifically, sex is a resource controlled by women who grant sexual access to men in exchange for other resources. The resources most commonly exchanged for sexual access are material goods and commitment. The exchange of material goods for sex can be seen in prostitution, the tradition of men paying for dinners, movies, and other activities, and in men expending money to access various forms of pornography. The exchange of commitment for sex is evidenced in the fact that most cultures have negative sanctions against both premarital and extramarital sex. Thus, men must offer commitment to a long-term marital relationship to gain sexual access to a partner. Social exchange theory also provides an explanation for the finding that women often view the sex industry more negatively than do men. The sex industry makes sex more readily available in the form of prostitution and pornography. In doing so, women's control of sexual access is diminished. Any increase in the availability of prostitution and pornography also makes sex a less scarce and, consequently, a less valued resource.

Concluding Remarks

In conclusion, social exchange theory has proved to be a useful approach to the exploration of social interactions. Much of its appeal lies in its simplicity and its application to a wide range of social exchanges and types of relationships. In addition, many of the basic principles (the desire to maximize profit or to engage in fair and equitable exchanges) are intuitively appealing to relationship researchers as well as to those engaged in less rigorous but no less serious contemplation of their interpersonal interactions.

EXCITATION TRANSFER THEORY

Acute emotions permeate all human relationships. In intimate groupings, frequent bouts of conflict and aggression characterize negative relationships, and frequent experiences of joint accomplishments and elation characterize positive ones. As a rule, relationships are shaped by both aversive and joyous emotions that occur with some regularity and that are often intertwined. Successive emotions are particularly interesting because their physical intensity tends to escalate from earlier to later ones. Such sequential intensification may boost ensuing joy. But it also strengthens aversive emotions such as anger and rage, thereby motivating hostile and aggressive actions that may imperil relationships. The Excitation Transfer Theory, described in this entry, addresses this phenomenon of emotion intensification, along with its behavioral consequences.

Excitation as the Driving Force in Acute Emotions

Excitation Transfer Theory focuses on physiological manifestations of bodily arousal. All vital emotions are known to be accompanied by elevated sympathetic reactivity, which is subjectively experienced as general excitedness. The primary function of this reactivity is to provide energy for a burst of action to allow the organism to cope effectively with acute behavioral challenges. Coping via immediate physical action is often unproductive in contemporary situations of challenge, so much of this energy provision has become useless, if not counterproductive. A man, for instance, after being apprised of a divorce settlement of devastating consequence to him, is bound to be superbly energized by rage, but is in no position to resolve the challenge to his advantage by beating up his estranged wife or the judge, nor by racing away from the courthouse. Energizing reactivity has been retained nonetheless, primarily because it is mediated by enduring brain structures, such as the amygdala. This reactivity generates agitation that favors action over inaction. Via feedback of skeletal-motor tension and cardiac acceleration in particular, the reactivity fosters cognizance of the degree of bodily arousal. It ultimately signals emotional intensity and thus drives the experience as well as the goal-directed expression of emotions.

Cognitive and Excitatory Adjustment to Environmental Changes

The time course of cognitive and physically energizing excitatory reactions to emotion-arousing changes in the environment differs greatly. Cognitive adjustment to such changes is quasi-instantaneous because of the exceedingly fast neural mediation of cognition. In contrast, the mediation of sympathetic excitation via the release of hormones into the blood circulation is lethargic, and excitatory adjustment to situational changes comes about only after considerable passage of time. Once instigated, this activity runs its course even after the instigating emotional challenge has ceased to exist and, because of rapid cognitive adjustment, another emotion has come about.

Emotion-Intensification by Leftover Excitation

Excitation Transfer Theory is based on the apparent discrepancy in adjustment time. Specifically, the theory predicts that whenever particular circumstances evoke an emotional reaction at a time when portions of excitation are left over from preceding emotions, the leftover portions combine inseparably with newly instigated excitation to produce excitatory activity whose intensity is greater than that specific to the new instigation alone. Leftover excitation may thus be considered to artificially intensify newly triggered emotions and thereby create "overreactions." It has been observed, for instance, that libidinal urges and sexual behavior engendered in the wake of furious quarrels tend to be extraordinarily intense. In the reverse direction, thwarted erotic desires tend to foster excessive hostility in unrelated subsequent disputes. In both cases, the leftover excitation from a prior emotion intensified a subsequent, different emotion, thereby making the artificially intensified emotion incommensurate with its actual instigation.

Evidence of Excitation Transfer in Anger and Aggression

Investigations of interpersonal conflict have shown that sympathetic excitation increases with the severity of threatened harm and that the intensity of fear, anger, and ultimately aggressive behavior increases along with rising excitation. It has also been demonstrated that under conditions of extreme agitation, concerns about future implications of aggressive actions diminish and aggression becomes impulsive and reckless. The preoccupation with immediate threat-deflecting actions apparently carries with it a neglect of non-immediate ramifications. The escalation of anger and aggression during acute conflict can thus be understood as a sequence of threats and counterthreats that successively increases excitation to levels at which a "cognitive deficit" is engendered and behavior becomes impulsive.

The excitatory escalation that creates a propensity for violent action is not limited, however, to chains of aggression-inspiring threats. As expected by Excitation Transfer Theory, sympathetic excitation from reactivity that is unrelated to fear and anger can

accumulate and then intensify aggression. It has been shown that leftover excitation from sexual instigation, or from strenuous physical exercise, is readily integrated and may fuel anger and aggression.

Research suggests that the escalation of excitation to levels that invite impulsive aggressive actions is best prevented by the early provision of information that mitigates apparent provocations. Information that shifts the perception of suffered aggravation away from a deliberate targeted attack toward incidental and unavoidable causes can curtail this escalation. In case such information cannot be provided, prevention of excitatory escalations can be achieved by a voluntary or imposed temporary truce or the separation of the feuding parties. Once excitation has dissipated, because of homeostatic control, the resolution of conflict is bound to be more within reason.

Evidence of Excitation Transfer in Joyous Emotions

Excitation associated with fear and anger is not inextricably linked to aggression. Residual portions of such excitation have been shown capable of intensifying amorous feelings and sexual experiences. In turn, leftover excitation from sexual enticements has been observed to intensify such diverse emotional experiences as anger, hostility, sadness, empathy, altruism, the appreciation of humor, and the enjoyment of music.

Considerable attention has been given to the transition from aversive emotions to joy and elation. Excitation left over from acute fear has been shown to fuel euphoria upon the successful elimination of the threatening circumstances. The phenomenon of suspense entails the same conversion. The more intense empathic apprehensions about others' failure and doom, the greater will be the joy upon finding these apprehensions groundless. This transfer-facilitation of joyous emotions is heavily exploited by the entertainment media. Fictional drama of any kind is laden with episodes in which the instigation of distress is promptly superseded by satisfying resolutions to the agonizing occurrences. Spectator sports, although less scripted, also follow the suspense format in providing the greatest enjoyment with games in which much agony precedes a yearned-for outcome.

Such facilitation may be less obvious in immediate human relationships but permeates them nonetheless. In intimate groupings, challenges abound and undoubtedly create ample distress and infurcation. Perhaps ironically, the more intensely these aversions are experienced, the greater will be the joy upon removing their basis by concerted, joined efforts. The frequent experience of this kind of emotional overcoming of challenges contributes greatly to satisfying human relationships.

EX-PARTNER AND EX-SPOUSE RELATIONSHIPS

Ex-partner and *ex-spouse relationships* are the ties between members of a former couple after divorce or relationship dissolution. The divorce rate in the United States remains around 40 percent, which means large numbers of people find themselves in postdivorce relationships. When children are involved, how former partners relate to each other is critical to their children's well-being. This entry describes perspectives that have been used to study ex-partner relationships and types of relationships that can form after dissolution for those who do not have children together as well as for those who share children.

Perspectives Used to Study Ex-Partner Relationships

Researchers who study relationship dissolution vary in how they view the resulting changes. Some take a problem-oriented or deficit comparison

perspective; they view divorce as an event or process that causes difficulty for adults and children and greatly disadvantages them when compared with adults in first married nuclear families. Others take a normative approach and view divorce and relationship dissolution as normal because of its frequency and not necessarily negative because some family members may benefit from the break. For example, if an abusive relationship dissolves, the dissolution may be positive for the person being abused and for the children who have been exposed to the abuse or who have perhaps been abused themselves. In a third approach, a stress and coping model is used, suggesting that over time, most people adjust to life changes brought about by relationship dissolution. The first 2 years following divorce are a time when parents experience personal and economic stress and are more likely to have higher levels of conflict with their former partner. As a result, these 2 years often affect children in a negative way. Children are more likely to have lower levels of academic success, have more emotional problems, and may act out. Over this 2-year period, however, most parents and children are able to adjust to the divorce.

Types of Ex-Partner Relationships

For former partners to continue a relationship after divorce, the relationship must be redefined. Part of this redefinition process includes negotiating and redefining boundaries. This postdissolution relationship may manifest itself in a number of different ways, depending partly on whether the ex-partners have children together. Regardless of the presence of shared children, intimacy and power boundaries must be addressed.

Childless Ex-Partner Relationships

Although relationships between former partners who do not have children are less likely to continue than are relations between those who share children, most childless ex-partners maintain some contact after divorce. There are a number of reasons for this. For example, they may continue to work together, they may share the same social circle, or they may want to maintain the friendship

they had before and during the marriage. They may also want to continue ties because of shared history, because of extended family relationships, and to maintain mutual support. Some couples can maintain close friendships but cannot tolerate each other's company on a day-in and day-out basis. There are few societal scripts, however, to guide former partners in how to relate with each other. There is also a prevailing assumption that ex-partners should be antagonists. If ex-partners remain friendly after divorce, others are often confused about why the relationship dissolved or they may make assumptions that the couple will reunite. New romantic partners often discourage ex-partner relationships. If intimacy boundaries are not renegotiated, ex-partners may continue such behaviors as having keys to each other's households, and sharing pets and expensive items such as snow blowers, lawn mowers, and vacuum cleaners. It may be disconcerting to a new romantic partner when an ex-partner bursts into the house, unannounced, sometimes at quite inappropriate times, to borrow the vacuum cleaner!

It is typically easier for couples to renegotiate power boundaries than it is to renegotiate intimacy boundaries. Some ex-partners view divorce as a chance to develop different roles than they assumed during the marriage. Other ex-partners may resist these changes and feel threatened by them. For example, if the husband was the main source of financial support for the couple or if the ex-partners have become dependent on each other for matters such as emotional support, routine household tasks, or financial management, divorce might introduce genuine crisis to their lives. Conflicts over power boundaries may result in prolonged and expensive legal disputes over property and money, among other things. Power boundaries are not really negotiated until both ex-spouses realize they no longer have control over the other.

The well-being of those involved in postdissolution relationships can be affected by the type of relationship that ensues. Those who are preoccupied with their former partner, have lingering romantic ties, and are overdependent on their former partner, or continue to have conflict with them, are more likely to have lower levels of well-being than are those who are able to retain reasonably friendly relationships.

Relationships for Ex-Partners With Children

Former partners who share children are likely to continue interacting following divorce and to participate in a *coparenting relationship*. A coparenting relationship exists when biological parents continue conjoint responsibility for their child's well-being and work together to raise their children. The children are the tie that connects former partners, although the relationship that ensues is now different because the two typically are no longer romantically involved. The couple must disengage from the spousal relationship but continue to relate as parents. Children who are biologically related to one parent and not the other (i.e., stepchildren), however, no longer have a connecting tie with the stepparent. Unless stepparents have adopted the stepchildren, they are not legally required to continue a relationship with them. In fact, stepparents often find that they can be legally prevented from having any contact at all with their stepchild even though they may have helped raise the children from birth.

Ex-spouses who share children are likely to have higher levels of interpersonal conflict and lower levels of well-being than are those who do not. There are a number of reasons for this. For one, they may be required by law to share custody of their child even though they would prefer to not interact with each other, whereas those who do not have children are more likely to maintain contact because they want to do so. For parents, arguments stemming from the difficulties of raising children as well as those surrounding parenting children from separate households (e.g., shared parenting time, child support amounts, how child support money is spent) can trigger conflict that would not exist for those who do not have children. Renegotiating intimacy and power boundaries can be quite stressful.

Clinical researcher Constance Ahrons identified five types of postdivorce coparenting relationships: Cooperative Colleagues, Perfect Pals, Angry Associates, Fiery Foes, and Dissolved Duos. Cooperative Colleagues and Perfect Pals are those who are able to maintain cooperative relationships following divorce. Approximately half of parents are Cooperative Colleagues—couples who are able to separate spousal disagreements from parental responsibilities. These parents manage to control

their conflicts to work together to parent their children. Cooperative Colleagues have negotiated intimacy boundaries and do not intrude unwelcomed into each other's personal lives and new relationships. These coparents are able to share their children's events such as graduation, weddings, school conferences, and sporting events with low levels of interpersonal stress. Good parenting plans provide boundaries that negate power struggles by clearly defining issues of shared time (e.g., what time a parent will pick up and return a child, where and when children will share holidays, birthdays, etc.). Even a well-designed parenting plan, however, does not solve all the problems related to the inevitable changes and contingencies that occur as children grow older. The parents have to have at least minimum motivation to cooperate for coparenting to work.

Perfect Pals consist of a small group of people (less than 5 percent) who remain best friends after the divorce and continue a nonsexual, intimate relationship with each other. These parents operate almost exactly as they did before divorce, except they no longer share a household. These ex-spouses continue to enjoy each other's company, but they have found it impossible to live together. They may cite things as simple as differing standards of household cleanliness as a reason for living apart. Some have grown apart as romantic partners over time but remain friends who share a heavy investment in their shared children. They maintain the rituals that the family enjoyed before divorce, plan special events such as birthday and graduation parties for the children, and jointly attend conferences and children's sporting, musical, and other events. Children appreciate their parents being Perfect Pals, but it only works if neither parent remarries. Perfect Pals are unlikely to have negotiated boundaries to the extent that is true of Cooperative Colleagues. This painful process may be avoided until one member of the former couple finds a new love interest.

Cooperative coparental alliances are possible and are beneficial for children and parents alike. When parents can cooperatively coparent, they and their children are more likely to adjust positively to the changes brought about by divorce or relationship dissolution. For parents to enhance the positive parenting environment, they should share information about the child with the other

parent, share responsibility for childrearing tasks, and be cordial and respectful toward each other.

Angry Associates and Fiery Foes are not able to cooperate, but instead have highly conflicted relationships. Approximately 20 percent of divorced coparents are Angry Associates who are unable to differentiate between spousal problems and parenting responsibilities. They often hold grudges, do not cooperate with each other, and may engage in parallel parenting, which means that they do not talk with each other about the children. These parents are not able to jointly attend teacher conferences, birthday parties, or other important events related to their children without acrimony.

Fiery Foes, about 2 to 5 percent of coparents, do not recognize each other's right to parent, and they go to great lengths to sabotage each other. These parents often have long, drawn-out custody battles and may resort to violence to seek revenge on their former partners. They cannot let go of hurtful things that happened during the marriage and refuse to recognize anything positive about their ex-spouses. This style of coparenting is the most likely to negatively affect children. Finally, Dissolved Duos no longer have contact with each other, and one parent, usually the father, no longer has contact with the children. This may reduce the children's exposure to parental conflict, but it leaves children feeling abandoned and unloved.

When there are high levels of conflict between the former partners as is the case with Angry Associates and Fiery Foes, children's well-being is negatively affected in many ways. They often have behavioral problems (they may act out or be depressed) and lowered academic success. Fathers are less likely to remain involved in the child's life when there are high levels of interpersonal conflict between him and his former partners. In addition to the diminished level of contact the child has with the father, the child's relationship with extended family members on the father's side is often cut off, which may at least reduce the richness of the child's social environment.

Most former partners, regardless of whether or not they have children, retain some contact after relationship dissolution or divorce, but the type of relationship that ensues can vary greatly. The ways in which the ex-partners interact with each other affects the well-being of the former partners as well as any children involved. When former

partners are able to successfully redefine their relationship, negotiate power and intimacy boundaries, and remain cordial to each other, all of those involved can benefit.

EXPECTATIONS ABOUT RELATIONSHIPS

Humans have many expectations for their interpersonal relationships. Relational expectations are assumptions or beliefs about how the self and partner typically think, feel, and behave in

relationships, as well as how relationships typically function. These expectations concern relationships in general, as well as expectations for specific relationships. Expectations are formed through the cultural environment, socialization, and personal experiences within relationships. Relational expectations are important because they influence both interpersonal behavior and individuals' evaluation of the quality of their relationships. This entry describes types of relational expectations and the mental organization of expectations.

Types of Relational Expectations

Social scientists have identified two types of relational expectations. People have both general relationship expectations and relationship-specific expectations.

General Relationship Expectations

General relationship expectations are those assumptions and beliefs concerning how people typically behave, think, and feel in relationships, as well as the nature of different types of relationships. These general expectations are formed from people's acceptance of cultural norms, parental socialization, observation of other's relationships, and people's own experiences in relationships. Because of these multiple influences, general relationship expectations tend to be widely held among those in a particular society.

Cultural Influences

The normative expectation for choosing a marital partner in Western cultures is that love should exist between the partners. In other cultures, equal social status between marital partners may be the predominant expectation. Cultures transmit their expectations through its institutions. Cultural expectations are transmitted through media portrayals of relationships, as well as by various societal institutions, such as the family (see further discussion later) or religious beliefs.

Parental Socialization

People's *general relationship expectations* also are influenced through parental socialization.

Parents influence these expectations through direct teaching about what to expect in relationships and by modeling interpersonal behaviors. For example, parents are likely to teach their children about what to expect in marriage, for example, spouses support you, spouses can be trusted. Children also observe their parents' interactions with other married couples. This modeling of parental behavior in relationships can lead children to internalize expectations about how relationships typically operate.

Observation of Other People's Relationships

People have multiple opportunities to observe others' relationships. People observe relationships in various media, their own and others' families, and those of their friends. Through these observations, people learn to expect certain things in their relationships. Not all observations are equally influential in the formation of expectations. People are most likely to be influenced by people who are important or similar to them. Thus, it is not surprising that parents are a powerful force in the development of relational expectations in their children. Similarly, adolescents' observations of their peers' relationships should be particularly important in influencing relational expectations.

People's Own Relationship Experiences

The development of general relationship expectations is not solely a passive process of observation. People's direct experience in their own relationships is an important force in the formation of their general relational expectations.

The seeds of relational expectations are sown early in children's lives. Early research showed that parenting styles are influential in the development of relational expectations, although many other factors also are important. Parents who are loving, nurturing, and dependably respond to their children's needs promote children who trust and are comfortable relying on their parents and others. Other parents are inconsistent with their children, providing love and nurturing at times, but not at other times. Such parenting leads children to be anxious about their relationships and unsure that parents and others are trustworthy. Other parents are hostile in their parenting styles, with some displaying rejecting behavior toward

their children. This parenting style can lead to children who emotionally withdraw and are distrustful in their expectations for others. Many researchers believe that these expectations acquired in early interactions with parents may carry over to their adult relationships. Consequently, in adulthood, some people will generally expect that others will like them and be trustworthy. These individuals are secure in their expectations about relationships. Some individuals will expect others to be relatively untrustworthy and undependable, whereas some people will expect others to be unpredictable, thus leading to insecurity in their expectations.

People's relational expectations do not completely depend on their experiences with parents. As children develop, they begin to experience relationships outside the family. They form relationships with peers, teachers, and romantic partners.

Relationship-Specific Expectations

As people begin to explore longer term relationships with friends, romantic partners, and others, they begin to form expectations about each of those specific relationships. People use their *general expectations* for relationships as an initial roadmap for what to expect from a specific partner. For example, in Western societies, there is a general expectation that relationships with others will be characterized by considerable equality between the two people. Consequently, on a first date, a woman will likely expect her dating partner to consider her likes and dislikes as they decide whether to have a meal together or engage in certain activities. However, if the man exhibits an attitude of male superiority by taking sole charge of where they go to eat and what they are going to do, her expectation about equality in that specific relationship may begin to change. Of course, his behavior might be the result of his general expectation that women prefer a male partner to take charge. In that case, further interaction in differing circumstances would allow the woman to develop more accurate expectations for the man's relational behavior. Consequently, if the relationship persists, the content of the woman's expectations for that specific relationship will become more detailed.

The Mental Organization of Expectations

Relational expectations, whether general or relationship specific, do not exist in isolation from each other in people's minds. In other words, when people have one expectation for a relationship, they tend to have other expectations that are related to the first one. For example, people who expect romantic partners to love them are also likely to expect those partners to be trustworthy. Relational expectations tend to be organized in what social scientists call interpersonal scripts or social schemas.

Interpersonal Scripts

Interpersonal scripts are mental representations that contain people's expectations for how certain events should unfold in an interpersonal interaction. For example, a common first date script for a heterosexual relationship contains the following expected events: The man asks a woman for a date, a decision is made about what to do on the date, the people groom themselves in getting ready for the date, the man picks the woman up at her home, they engage in recreational activities, they share a meal, the woman is taken back to her home, and then the daters tell each other that they had a good time and say goodbye. Other interpersonal scripts exist, such as scripts for a sexual encounter.

Social Schemas

Social schemas are mental representations of one's knowledge or expectations about social concepts (e.g., love, commitment) and social relationships. For example, people have many related expectations for what it means to be "committed" (a social concept) to a relationship. They expect their committed partners to show their commitment through loyalty, living up to their word, persevering in hard times, and so on. People also have social schemas for different types of social roles. People typically expect their parents to love them, to protect them, and teach them how to handle life's difficulties. These scripts and schemas are important in the functioning of relationships.

The Importance of Relational Expectations

Relational expectations play an important role in relationships, possibly more so at present than

in the past. For example, in the 19th and early 20th centuries in the United States, expectations for a marital partner were relatively straightforward. Expectations for a marital partner focused on the practical qualities of the partner that could lead to a successful economic union. Today, people expect marriage to be a source for personal growth and happiness. Consequently, when such expectations are not met, serious consequences can result. Social scientists have speculated that the relatively high divorce rate in Western society is a result of these inflated expectations.

Expectations have consequences for relationships in two ways: (1) They act as guidelines for behavior in interpersonal relationships, and (2) they assist in assessing the quality of those relationships. Expectations influence the establishment, maintenance, and dissolution of interpersonal relationships. The following sections illustrate how relational expectations can influence interpersonal relationships at these different phases of relationships. However, the discussion of one type of expectation at a particular phase does not mean that the same expectation is irrelevant at other phases. In addition, expectations are only one factor that influences the course of relationships.

Establishing Relationships

General relational expectations are important in the process of beginning a relationship. These expectations can either facilitate or interfere with the establishment of relationships. These potential influences can be illustrated using a fictional example of a first meeting between two people, Mark and Amy. Mark, a psychology major, is attending a get-acquainted function sponsored by his mixed-sex residence hall at the university. As he walks in, he notices an attractive woman, Amy, standing alone at the refreshment table. Mark is interested in exploring possible dating partners, so he considers approaching Amy.

Facilitation by general expectations might proceed as follows: Mark's general script for a first meeting includes an expectation that men initially approach women in such situations, thus he feels comfortable initiating an interaction with Amy. Amy's attractiveness also influences Mark's decision about approaching her. Considerable research shows that individuals

tend to *expect* physically attractive people to be more socially skilled, make better marriage partners, and make better lovers than those who are less attractive. Consequently, Mark decides to approach Amy.

The next task in a first meeting is to behave toward the other in a way that promotes feelings of rapport. Relational expectations also will influence how Mark attempts to build rapport. During his life, Mark has enjoyed trusting, caring, and comfortable relationships with his parents, peers, and former dating partners. Consequently, Mark has generally secure expectations for his relationships and will enact behaviors that promote rapport. Researchers have found that people with generally secure versus insecure expectations are likely to engage in higher levels of appropriate self-disclosure in initial encounters and are more responsive to the disclosures of the potential partner, thus promoting rapport. In addition, Mark's generally secure expectations (e.g., trust) for a potential partner are likely to result in Amy displaying similarly secure behaviors. This phenomenon is known as the self-fulfilling prophecy. Simply stated, the self-fulfilling prophecy holds that when people have an expectation for other individuals, those others tend to behave in ways that confirm the first person's expectations. Thus, when Mark competently communicates with Amy, she matches his behavior with her own competent communication. This ongoing reciprocal communication is likely to lead to rapport between Mark and Amy, which bodes well for further development of a relationship.

In contrast to this scenario, people's general relationship expectations also can interfere with the establishment of relationships. Mark may have a history of poor relationships with his parents, friends, and past romantic partners. Consequently, Mark's general expectation of failure in relationships makes him anxious about starting relationships. Research shows that this anxiety is associated with an impaired ability to approach other people for a relationship effectively. Mark's anxious insecurity may lead him to approach Amy by emphasizing his weaknesses to gain her sympathy. Such an approach lessens the chance that Amy will be attracted to Mark. In addition, Mark's insecure or anxious expectations can lead him to be extraordinarily sensitive to any sign that Amy may not be

attracted to him. For example, if during their conversation, Amy looks away for even a fleeting moment, Mark may interpret that as a lack of interest in him, even if that was not Amy's intention. Mark may then decide to terminate the interaction.

If Mark and Amy's first meeting results in future encounters, the potential exists for their relationship to become more committed. General relationship expectations also are involved in these increases in commitment. Two types of expectations are particularly significant. Relationships scientists have shown that people are satisfied with a relationship to the extent that their present relational rewards exceed their *expectations* for what they generally receive in a relationship. Consequently, if Mark and Amy perceive that their relationship is yielding higher rewards than what they generally *expect* (based on a comparison with past relationships), they will experience satisfaction, which contributes to the development of commitment. In addition, people also have expectations for what they *should* receive in their relationships. In other words, people have expectations, what social scientists call *standards*, for ideal mates. These general relationship expectations develop over time as people internalize cultural expectations for relationships, and through their interactions with parents, peers, and past relationship partners. Relationship researchers have found that the extent to which people believe their partners meet (versus not meet) their expectations for an ideal partner, the more likely they are to persist in those relationships. Consequently, if Amy and Mark believe that the other meets their ideal expectations, the relationship is likely to become more committed.

Maintaining Relationships

If some level of commitment develops over time between Mark and Amy, general relationship expectations will continue to play a role in their relationship. However, both Mark and Amy will begin to form specific expectations for each other and their relationship as they continue to interact after the first meeting. Some of these specific expectations will be similar to their general relationship expectations, whereas others will be based on their experiences with each other. For example, Mark generally expects that men will initiate

interaction with dating partners. However, after a few dates, Amy occasionally calls Mark to see if he wants to “go out.” Over time, Mark may form a specific expectation that it is acceptable for Amy to initiate activities with him, although his general expectation may not change. Other specific expectations for each other will develop as they continue to interact.

As commitment grows between Mark and Amy, so do relationship-specific expectations that the other is trustworthy. These expectations play an important role in helping people maintain their relationships. People in relationships who have trusting expectations of their specific partners evaluate those partners in a way that promotes positive outcomes. Research has demonstrated that people who have higher expectations (versus lower expectations) that their partners are trustworthy interpret their partners’ behaviors relatively more positively, as well as discounting the influence of any negative partner behavior. For example, since trusting expectations have developed between Mark and Amy, a negative remark from Mark about Amy’s being late to meet him for dinner is not construed by Amy as a threat to their relationship. In turn, Mark does not conclude that Amy’s lateness is a sign of waning commitment. Consequently, this and similar interactions help maintain this relationship. In addition, maintenance of Mark and Amy’s relationship will also depend on an ongoing assessment by each of them that the rewards they are receiving are greater than what they generally expect to receive in relationships (see earlier discussion of this issue).

Deteriorating Relationships

Relational expectations also can contribute to the deterioration of relationships. Mark and Amy’s relationship could have taken a downturn at any point after their first meeting. Expectations are involved in the deterioration of relationships in at least two different ways.

Relationship problems often arise from one or both partners having unrealistically high general expectations for their partners and relationships. Relationship researchers have uncovered five basic unrealistic expectations: (1) disagreement is destructive, (2) mind reading is expected, (3) partners

cannot change, (4) sexual performance must be perfect, and (5) the sexes are different. Social scientists have shown that possessing such unrealistic expectations is associated with dysfunction in interpersonal relationships (e.g., negative problem solving, lowered satisfaction). Amy may generally expect that good relationships are free of conflict. This expectation leads Amy to question the quality of her relationship with Mark when there is the least hint of disagreement. In addition, Amy may be reluctant to express any disagreement with Mark. Consequently, problems are not dealt with and accumulate over time, possibly leading to a later emotional outburst.

Relationship specific expectations also can play a role in the deterioration of relationships. Over time, people develop many expectations specific to their present relationships. Amy, through her repeated interactions with Mark, likely develops a set of expectations (e.g., a social schema) about him as her committed partner. She expects Mark to be dependable, trustworthy, and caring. However, their relationship could begin to deteriorate if Mark begins to violate Amy’s expectations for him as a committed partner, thus resulting in a change of her expectations.

Relationship researchers believe that changes in specific relational expectations occur via two processes. For example, if during the past 2 months Amy has noticed that Mark has failed to follow through on several promises that he made to her. Researchers suggest that Amy’s expectations for Mark will change when his undependable behavior reaches a certain level, essentially a bookkeeping process. On the other hand, a sudden change in expectations for Mark can occur when Mark severely violates Amy’s expectation for dependability, which is a conversion process. Either process can lead to deterioration of the relationship.

In conclusion, relational expectations are important in the functioning of interpersonal relationships. They can play a positive or negative role in interpersonal relationships. Future research is likely to bring a better understanding of their role in relationships.

EXPECTATION STATES THEORY, APPLIED TO RELATIONSHIPS

In his book *The Power of Positive Thinking*, Norman Vincent Peale famously noted, “If you paint in your mind a picture of bright and happy expectations, you put yourself in a condition conducive to your goal.” As this quotation suggests, expectations are related to behavior and ultimately to success. Expectation States Theory, which was developed by Joseph Berger and his colleagues, helps explain how judgments about status influence perceptions and performance in task-oriented groups. Other related theories focus on how expectations are related to emotions and communication in personal relationships. This entry describes both these areas of research.

Expectation States Theory

Expectation States Theory examines how status cues influence expectations and encourage particular behaviors within task-oriented groups. *Expectation states* refer to beliefs about a person’s competence and ability to contribute to a group

task. These expectations are based on status cues such as clothing and accessories, physical appearance, accent, posture, use of technical jargon, age, and gender. According to the theory, when group members first meet, they evaluate one another and form initial expectations based on these status cues. People who possess high status cues are expected to be more competent, influential, and successful than are those possessing low status cues. These expectations then work as self-fulfilling prophecies. People who are expected to be competent are given more opportunities to succeed, more positive feedback, less criticism, and more cooperation from others, all of which increase their confidence and their ability to influence others and succeed. In contrast, group members who are perceived as low status are rebuffed and disliked if they try to assert power or authority.

In addition to general expectation states, the theory proposes that people develop *self-to-other performance expectations*. The idea here is that when people first come together in groups, they make implicit comparisons between themselves and others to better understand their roles. When people have low performance expectations, they are likely to be fairly passive, ask others for information, be easily influenced by others, and evaluate other people’s suggestions favorably. In contrast, people who have high performance expectations are more likely to share ideas, be critical of others, and take leadership roles.

Although Expectation States Theory was developed to apply to task-oriented groups, other scholars, such as Cecilia Ridgeway, have used the theory to explain gender inequality in relationships between men and women. Ridgeway has argued that expectations based on gender stereotypes produce a network of constraining beliefs and behaviors that prevent women (who are viewed as having less status than men) from succeeding in the workplace. According to this view, expectation states help explain why women are evaluated more harshly than men when they act aggressively; because they are seen as lower in status, women are expected to engage in behavior that is conciliatory and cooperative rather than authoritative and competitive. Expectation States Theory also helps describe the perceptual biases and processes that lead women to hit “glass ceilings” and be overlooked for promotions. The theory suggests that

this happens because women are not expected to perform well, leading others to overlook or dismiss their accomplishments.

Implications for Relationships

Other expectation-related theories, such as Mary Levitt's Social Expectations Model and Judee Burgoon's Expectancy Violations Theory, have been applied to close relationships. In these theories, *expectation states* are cast broadly as beliefs about what will or should occur in a given situation based on individual knowledge about a person or social norms. For example, a wife might expect her husband to be outgoing at a party because that is how he normally acts, and most people likely expect more small talk than intimate disclosure on a first date. Similar to the premises underlying Expectancy States Theory, these types of expectations are theorized to act as roadmaps that help people predict, explain, and reduce uncertainty about their own social behavior as well as the social behavior of others.

In relationships, as in work groups, expectancy states influence perceptions and behaviors. People in happy relationships tend to expect their partners to be pleasant, whereas people in unhappy relationships tend to expect their partners to be unpleasant. These expectations can become self-fulfilling prophecies because partners look for behaviors that confirm their expectations. When people expect negativity in their relationships, they also tend to interpret positive or neutral behaviors more negatively. For instance, if a husband expects his wife to be critical when he tells her about a problem, he may hear a negative tone in her voice that objective observers would not hear. This perception of negativity can then lead to conflict. Of course, people can also have unrealistically high expectations that are difficult, if not impossible, to fulfill. They may believe their new relationship will solve all their problems, their good looking partner is as perfect as he or she looks, or having a baby will restore closeness in their marriage. Such high expectations often lead to disappointment and disillusionment.

Theories such as the Social Expectations Model and Expectancy Violations Theory have also extended work on expectations by distinguishing

between expectancy-confirming and expectancy-violating behavior. Expectancy-confirming behavior often goes unnoticed because it is consistent with what people imagined would happen. In contrast, people tend to notice and evaluate unexpected behavior. *Positive expectancy violations*, which occur when an unexpected behavior is evaluated as better than what was expected, lead to positive emotions such as joy and affection. *Negative expectancy violations*, which occur when an unexpected behavior is evaluated as worse than what was expected, lead to negative emotions such as anger or disappointment.

The same behavior can be evaluated differently depending on the initial expectancy state. For example, imagine that Christa and Maria both receive flowers and a card from their husbands on Valentine's Day. If Christa's husband usually forgets to do anything on Valentine's Day, his behavior would be evaluated as better than expected, constituting a positive expectancy violation. In contrast, if Maria's husband usually purchases an expensive gift for Valentine's Day, the flowers and card would be evaluated as worse than expected, constituting a negative expectancy violation. Even though the two husbands gave the same gift, Christa would be happier than Maria. Thus, as the quote by Peale at the beginning of this entry suggests, there is indeed a connection between expectations and emotions such as happiness.

EXPERIMENTAL DESIGNS FOR RELATIONSHIP RESEARCH

Research is a cyclical process. Theories shape research questions, and the outcomes of the research process in turn shape theories. A critical component in this cycle is the research methods that are used to gather data for testing hypotheses. This entry discusses the benefits and limitations of using experimental designs to test hypotheses in the field of relationship research.

Experimental Designs

The main focus of experimental research methods is on how different social or situational contexts influence people's responses (e.g., their thoughts, feelings, or behaviors). In a basic experiment, the researcher introduces a treatment to one group of participants (i.e., the experimental group) and withholds treatment to another group of participants (i.e., the control group). Critically, all study participants are randomly assigned to each group, helping ensure that participants in each group do not differ, on average, in any meaningful way from each other. Additionally, all study procedures are identical across the groups except for the treatment introduced by the researcher. The researcher then assesses all participants on the same dependent variable(s) of interest, and compares the scores from participants in the experimental and control groups to determine if the treatment had the intended effect. Any differences that emerge between participants placed into the experimental or control conditions are attributed to the treatment rather than extraneous factors. The control of extraneous factors and the isolation of key experimental manipulations allow the researcher to make cause and effect conclusions, which is the major benefit of experimental methods.

To illustrate the implementation of an experimental design in relationship research, consider a study conducted by Clive Seligman and colleagues that tested the hypothesis that in the context of a committed romantic relationship people would feel more love for their partners when they perceived their own motives for being with their partners as intrinsic (i.e., enjoying the qualities of their partners for their own sake) rather than extrinsic (i.e., enjoying the qualities of their partners because they serve other ends). Couples participating in this research were randomly assigned to one of three treatment conditions. Participants were asked to complete a number of open-ended sentences containing either the prepositional phrase *because I* (e.g., I seek out my girlfriend/boyfriend because I . . .), or *in order to* (e.g., I seek out my girlfriend/boyfriend in order to . . .). Prior research had shown that the phrase *because I* established an intrinsic mindset and the phrase *in order to* established an extrinsic mindset. In a third (control) condition, participants simply completed the set of dependent variables. The primary dependent variable was the degree to which participants reported loving their partner, assessed after the experimental treatments had taken effect. Compared with people in the control and intrinsic motivation conditions, people in the extrinsic motivation condition reported lower levels of love for the partner when led to believe that they were with their partner as a means to achieve other ends. No mean differences in reported love emerged, however, between the control and intrinsic motivation conditions. The use of an experimental design allowed the researchers to conclude that an extrinsic motivation for maintaining a romantic relationship caused people to feel less love for their partners.

In the previous example, the researchers might have used other research methods to test their hypothesis. For example, they might have asked a sample of participants the degree to which they were with their partners for both intrinsic and extrinsic reasons and how much they loved their partners. Scores on these three variables could then have been correlated within the sample. Presumably, scores on the intrinsic motivation and love scales would have been positively correlated, showing that love was greater when people possessed more intrinsic reasons for being with their partner. Similarly, scores on the extrinsic motivation

and love scales would have been negatively correlated, showing lesser love when people report more extrinsic reasons for being with their partner. The primary limitation with this correlational approach is that a correlation describes a relation between two variables, but does not speak to the direction of causation between them. For instance, it is not known if type of motivation for being with a partner causes feelings of love or whether feelings of love cause different types of motivation to be felt in a relationship. Additionally, an unmeasured third variable could be responsible for the type of motivation people feel for being with their partner and feelings of love. Carefully controlled experiments, therefore, are the most compelling method for providing evidence of cause and effect relations between the manipulated variables and study outcomes.

Limitations of Experimental Designs for Relationship Research

To conduct an experiment, researchers must have the ability to control and manipulate the factors under investigation. Many factors in field of relationship research, however, are outside the researcher's control. On the one hand, there are some things that researchers simply cannot control, such as who will fall in love, or who will become a parent and who will not. For example, researchers are not able to randomly assign people to a "one child" treatment, a "three child" treatment, or a "no child" control group to determine if having more children causes people to, for example, experience declines in physical and mental well-being compared with having fewer or no children.

On the other hand, some events are beyond the ethical reach of experimentation. It would not be ethical, for example, to assess the impact of infidelity on people's negative feelings toward their romantic partners by comparing the affective reaction of one group of people falsely told that their partners had admitted to many recent sexual affairs with another group of people provided no such information. Overall, researchers are expected to cause no serious harm to individuals or their relationships with their experimental manipulations. Testing certain types of hypotheses in

relationship research via experimentation is therefore a challenging task.

Concluding Remarks

Experimental designs for relationship research need to focus on variables that can be controlled, while taking special care to investigate, but not harm, potential or existing relationships. It is worth the effort of designing experiments that meet these two criteria given the power of experimental designs to provide evidence for cause and effect relations. The development of knowledge in relationship science is greatly assisted by the prominence of experimentation in the researcher's toolbox.

EXPRESSED EMOTION

Expressed emotion is a rather confusing term. It does not refer to a person's willingness to show emotions. Rather, it refers to a measure of the family environment that has been linked to psychiatric patients doing worse clinically after they

are discharged from a treatment facility. This entry describes how the construct was originally developed, discusses how it is measured, and explores its correlates and consequences.

Origins and Measurement

More than 50 years ago, a British sociologist named George Brown made a surprising observation. Brown and his colleagues noted that male patients who were suffering from chronic schizophrenia did much better after they were discharged from the hospital if they went to live in lodgings, or with siblings, rather than returning home to live with their wives or their parents. The finding that patients did better when they did not live with their families was unexpected. At the time, there was little in the British psychiatric literature that might have led anyone to think that social experiences might play a role in the course of schizophrenia. The unusual finding led Brown and his collaborators to begin systematic research designed to explore the possible role that family relationships might play with respect to clinical outcome in schizophrenia.

A major insight here was that it was the more everyday aspects of family relationships that were thought to be important, not relationships that were pathological or extremely disturbed. Brown and his colleagues began a series of studies designed to measure the emotional climate that existed in the family. This work resulted in the development of the expressed emotion (EE) construct.

The most accepted way of measuring EE is through an interview with the patient's key relative (usually a parent or a spouse); this is conducted in the absence of the patient. The interview is known as the Camberwell Family Interview (CFI). It is semistructured, and it takes about 1 to 2 hours to complete. Although the CFI contains specific questions about the development of the patient's psychiatric difficulties and asks about specific symptoms, it is also designed to provide the relative with an opportunity to talk and tell his or her story. There is a focus on how the relative deals with difficult situations involving the patient. Other questions concern the relationship between the relative and the patient and how they get along on a day-to-day basis.

Ratings of EE are derived from the relative's tone of voice when speaking about the patient as well as from what he or she says during the CFI. Because of this, the CFI must always be recorded for later coding. Training to rate EE is time-consuming and sometimes difficult to obtain. However, after approximately 2 weeks of training, coders are able to rate the elements of EE quite reliably. Coding EE takes approximately 4 hours per recorded interview.

Three key elements are used in rating EE: criticism, hostility, and emotional overinvolvement. The most important of these is criticism. Critical remarks are remarks that indicate clear dislike or disapproval of some aspect of the patient's behavior (e.g., "He stays up late watching TV and makes a lot of noise when the rest of us are trying to sleep. It's so frustrating and annoying."). Critical remarks are rated as such either because they contain critical content or because the relative uses a negative voice tone when speaking about the patient.

Hostile remarks are conceptually related to criticism in that they reflect dislike or disapproval. However, the degree of negativity is much more extreme. Hostile remarks include comments that are rejecting of the patient ("Sometimes I don't even want to be in the same room as him"). Remarks that indicate dislike of the patient as a person ("She's very selfish—doesn't care about anyone else but herself") are also coded as hostile.

The third element of EE is emotional overinvolvement (EOI). EOI is not like criticism or hostility. Rather, it reflects dramatic, exaggerated, overprotective, or devoted attitudes or behaviors toward the patient by the relative (e.g., "It breaks my heart to see him suffering. I'd do anything for him if it would help. There's nothing I wouldn't do for that boy."). EOI attitudes and behaviors are much less common than are critical or hostile comments. When found, they tend to be seen more in parents (especially mothers) than in other kinds of relatives.

To be classified as high in EE, relatives either need to make an above-threshold number of critical remarks, show any evidence of hostility, or score high (3 or more) on a 0–5 scale of EOI. The cutting scores that are used for criticism vary according to the diagnosis of the patient. If relatives of schizophrenia patients make six or more critical remarks

during the CFI, they will be classified as being high in EE. For relatives of patients with unipolar depression, however, a lower cutting score (two or three critical remarks) is used. The differences in cutting scores derive from empirical research on the predictive validity of EE and may reflect diagnostic differences in sensitivity to criticism. In cases where patients live with more than one relative (e.g., two parents), the family is classified as high in EE if at least one of the relatives is so rated.

In addition to rating criticism, hostility, and EOI, coders also rate (on a 0–5 scale) how much warmth the relative expresses when talking about the patient and how many positive comments about the patient (frequency count) he or she makes. These ratings are not considered in the overall (high versus low) EE classification, however. The reason for this is that, in Brown et al.'s early study, warmth was negatively correlated with criticism and very high warmth was associated with EOI. Unfortunately, this has led to a general neglect of the possible link between positive characteristics of families and risk for relapse.

Alternative Measures of Expressed Emotion

In the assessment of EE, the CFI is undoubtedly the measure of choice. However, the CFI is a time-consuming measure to administer and to score. This has led to the development of several alternative forms of assessment. Some of these involve questionnaires. Another common alternative measure is the Five Minute Speech Sample (FMSS). This requires the relative to talk about the patient for 5 uninterrupted minutes. The FMSS has been used by researchers studying childhood psychopathology and, to a more limited extent, in the study of schizophrenia and bipolar disorder. Although learning to code the FMSS still requires training, assessing EE with this measure takes much less time. One problem with the FMSS, however, is that, when compared against the criterion measure of the CFI, the FMSS tends to under-identify high EE relatives.

Expressed Emotion and Relapse

Expressed emotion is important because it is a predictor of relapse. When patients with schizophrenia

live with families rated as high EE, they have a risk of relapse that is more than twice the relapse rate found in patients living with low EE relatives. The association between high EE and increased risk for relapse in schizophrenia patients has been replicated many times and in many countries. High levels of family EE are also predictive of higher rates of relapse in the 9 to 12 months after treatment for major depression and bipolar disorder. Although most of the research on EE has involved patients with schizophrenia and mood disorders, studies have also examined EE as a predictor of clinical outcome in other forms of psychopathology including anxiety disorders, substance abuse, eating disorders, and borderline personality disorder. In general, these have shown that high family levels of EE predict worse clinical outcomes (shorter time to relapse, poorer functioning after treatment) in patients. An exception concerns patients diagnosed with borderline personality disorder. Research suggests that criticism and hostility are unrelated to clinical outcome in patients with borderline personality disorder and that high levels of emotional overinvolvement predict *better* clinical functioning at 1-year follow-up. Perhaps, for patients with strong emotions and abandonment concerns, there is something positive about the high levels of devotion, overprotection, and emotional expressiveness that are central to the EOI construct.

Understanding High EE

Because EE is measured in relatives and predicts poor clinical outcomes in patients, researchers initially assumed that EE was indexing something negative about relatives that played a causal role in the relapse process. This idea was consistent with behavioral observations that showed that, during face-to-face interactions with patients, high EE relatives were more critical, disagreed with patients more, and showed higher levels of nonverbal negativity than did low EE relatives. However, studies have also indicated that negativity is often apparent in both the relatives and the patients. Rather than being thought of as a construct that blames family members, EE is perhaps best regarded as a measure of a set of *patient-relative relationship problems* that are important for the relapse process.

Although the question of why EE predicts relapse is far from resolved, research supports the idea that EE may play a causal role in the relapse process. When families receive family-based interventions designed to reduce aspects of high EE, relapse rates in patients (who are already receiving medications) are reduced. This is true for patients with schizophrenia and for patients with bipolar disorder. Family-based interventions typically provide relatives with education about the illness. They also aim to improve communication and problem solving within the family.

Although the success of family-based interventions in reducing patients' relapse rates supports the idea that EE may play a causal role in the relapse process, it is important to avoid an overly simplistic and unidirectional view of EE. Family-based interventions may benefit families in many ways and changes in EE are not always necessary for patients to show clinical improvement.

The fact that two relatives of the *same* patient can sometimes have *different* levels of EE suggests that EE is not a simple reaction to symptoms or characteristics of the patient. Instead, EE should be thought of as a bidirectional construct. Current theoretical models emphasize dynamic and transactional processes, regarding high levels of EE as the product of failed (and often well-intentioned) coping efforts by the relative. More specifically, certain characteristics (such as an internal locus of control or a less flexible personality style) are thought to make it difficult for relatives to accommodate to patients' functional impairments or challenging behaviors. If relatives attribute patients' behavioral impairments to personal and controllable factors, they may make efforts to get patients to behave differently. If these efforts fail, tension and frustration are likely to result. Over time, unless the relative is able to adjust his or her expectations (or the patient is able to change his or her behavior), the family climate will become increasingly negative. The culmination of this is criticism and hostility in relatives and an emotional climate in the home that is stressful for all.

New directions in EE research are now bringing this decades-old construct into the era of affective neuroscience. Using functional neuroimaging, researchers are exploring the link

between EE and relapse more directly by examining how criticism from a close family member is processed in the brain. Findings from studies involving depressed patients suggest that even when fully recovered and symptom free, people who are vulnerable to depression do not process criticism in the same way that healthy controls do. More specifically, when they are exposed to critical comments from their own mothers, people vulnerable to depression show more activation in amygdala and less activation in dorsolateral prefrontal cortex and anterior cingulate cortex compared with healthy controls. Criticism may be important in the relapse process because it is capable of perturbing some of the neural circuitry that underlies vulnerability to psychopathology.

EXTENDED FAMILIES

This entry will discuss definitions of extended family, the diversity and complexity of extended family membership in contemporary societies, the significance and meanings of extended families, and types of extended family relationships being studied. Definitions of *extended family* (also called *kin* or *kinship group*) generally include relatives beyond immediate family relationships. Thus, extended family is a concept that extends past the definition of immediate family. Ways of defining immediate family have undergone change in the past few decades because of increased diversity in family structures. Many now recognize that immediate families can include not just heterosexual married spouses and their children but also cohabiting partners, same-sex partners, stepparents and stepchildren, grandparents raising grandchildren, and other relationships as well. This entry will consider extended family the legally, biologically, and voluntarily related kinship group that extends past the immediate family of parenting adults, their spouses/partners, and minor children.

Diversity and Complexity

Several trends have contributed to the great diversity of extended family relationships today. Many countries have experienced declines in fertility, which has resulted over time in fewer siblings, aunts, uncles, cousins, nieces, and nephews than in the past. At the same time, many countries are experiencing increases in life expectancy, resulting in a rise in the number of family generations alive at the same time (and the potential for more active relationships between grandparents and grandchildren). China, with its one-child policy, is an extreme example of how extended family relationships can change with reductions in fertility and increases in life expectancy. As the one-child policy continues, more of the younger generations will be without siblings, aunts, uncles, cousins, nieces, and nephews. Chinese extended families fit with Vern Bengtson's idea of the "beanpole family," which has several generations alive at once but few members of any one generation.

Other trends contributing to the diversity of extended family relationships include high rates of

divorce, remarriage, and cohabitation, resulting in more half- and step-relatives. Along with the increased visibility of same-sex partnerships and the retention (in practice) of relationships with ex-partners or former partners and relatives, these trends create extended families that are complex, diverse, and influenced by personal choice. Thus, when scholars refer to extended families, the meaning may extend beyond grandparents, grandchildren, non-coresidential parents, adult children, aunts, uncles, cousins, nieces, nephews, and in-laws to include cohabiting partners of family members, godparents, former step-relatives and in-laws, foster relatives, "fictive kin" (voluntary kin), and "chosen families" (voluntary kin chosen to be part of gay, lesbian, and bisexual networks). These relationships reflect the discretionary and fluid nature of extended family ties in contemporary societies.

Meaning and Significance

Extended families are often considered significant in the various types of support they offer. Different types of support are possible with geographic nearness, so proximity and coresidence are often considered along with support. Extended families also serve as a fall-back group when immediate families are unable to provide for their members, especially children. This safety net function is vital to the well-being of many families, and the literature on this topic spans numerous countries.

Research about levels of proximity, contact, and support among extended family members often focuses on particular kinds of extended family members: adult children and siblings. The literature conceptualizes support in several subareas: financial, emotional, and practical. Racial and ethnic group differences in extended family patterns have been a topic of examination for some time, with researchers debating and trying to distinguish the relative effects of cultural and structural predictors on extended family outcomes. For instance, Natalia Sarkisian, Mariana Gerena, and Naomi Gerstel's recent study using national data in the United States found that Mexican Americans experienced higher levels of coresidence, proximity, and practical support with extended families than European Americans did. On the other hand, European Americans gave higher levels of financial support to extended family members than Mexican

Americans did. Social class factors were found to be much more important than were cultural factors in explaining these differences; higher income and education levels among European Americans put them in a better position to give money or goods to extended family members, and the weaker socioeconomic position of Mexican Americans helped explain their greater propensity to live and exchange practical support with one another.

Other research has posed similar questions, comparing European Americans with African Americans. Although European Americans appear to have more socioeconomic resources to share with extended families than do African Americans, evidence indicates that African Americans receive more practical support from extended family members. This suggests that differences between racial/ethnic groups in the United States in their levels of extended family support may have more to do with social class than with cultural differences. Cultural factors may be somewhat relevant as well, as shown in the finding that African Americans experience stronger extended family ties through siblings and fictive kin than European Americans do.

Extended families are also recognized as significant safety nets or backup groups that can provide care to children when immediate family members are unable to. For instance, the foster care system in the United States tries to take advantage of the availability of extended family members as caregivers to children who cannot live with their parents. Extended families are seen as more desirable than strangers to be caregivers of foster children, and they may continue to have access to children they have helped raise if those children become reunited with parents. The topic of grandparents raising grandchildren has been a popular research topic in recent years.

From a global perspective, extended families often provide vital support to children whose parents may have died or become incapacitated. The AIDS pandemic in Africa is a prime example of a large-scale problem that is decimating nuclear families in many places and causing extended families to take on the roles of surrogate parents for vast numbers of children. For example, Tatek Abebe and Asbjorn Aase found that Ethiopian extended family members such as grandmothers and uncles took responsibility for orphaned

children after their parents died, and that children were often more comfortable being cared for by extended family members who had been particularly close to a deceased parent. A range of extended family caregiving situations was identified, with caregivers fairly evenly distributed across a four-category continuum: rupturing (chronically impoverished), transient (relatively poor and deteriorating), adaptive (relatively secure economically and well functioning), and capable (economically and socially viable, even without outside assistance). Extended families considered orphaned children to be economic assets particularly in rural areas, where the children could contribute to the family economy through working in crop production and household activities.

Types of Extended Family Relationships Being Studied

Research on U.S. extended families often focuses on relationships between individuals who at an earlier point in the life course would have fit the idea of "immediate family" or "nuclear family" or "family of orientation." These relationships include adult children and their parents and siblings. This is contrary to what many would expect when thinking about extended families and seems to reflect a relatively narrow examination of extended families by researchers. Perhaps Western family practices place the greatest priority on closely related relatives who over time no longer coreside but act as significant extended families to one another. There is a large gerontological literature on parents and adult children across the life course that is not explicitly designated or thought of as research on extended families, but could be better integrated with it.

Beyond parent-adult child and adult sibling relationships, extended family scholarship is focused heavily on relationships between grandparents and grandchildren. Increases in life expectancy have generated more interest in multigenerational families, and the phenomenon of grandparents raising grandchildren has caught the attention of researchers and the public. A notable example of extended family research on grandparents is Colleen Johnson's exploration of how the extended family networks of California grandparents have shifted

over time with the divorces and remarriages of children. Grandmothers' networks could expand in four different ways after a child's divorce: (1) when relationships with relatives of a child's divorce were retained, while new relatives were added after a child's remarriage, (2) when the divorces and remarriages of multiple children created several subsets of relatives, (3) when the divorces and remarriages of grandparents added another set of step and in-law relations, and (4) when they retained relationships with former children-in-law after these children remarried. Johnson found that extended families often reflected a matricentric focus, with paternal grandmothers connecting with their grandchildren through ongoing ties with their former daughters-in-law (who were usually the primary physical custodians of the grandchildren). Johnson's research also contributes to the idea that "kinkeeping" with extended family members is a practice predominantly performed by women.

Other kinds of extended family dynamics seem to have been understudied, such as research on aunts, uncles, cousins, nieces, and nephews. This is especially true of family research focused on Western, industrialized countries. Robert Milardo's research on uncles and nephews fills a gap in this area. His work in New Zealand and the United States revealed diverse connections between these extended family members. Uncles often served as family historians, mediators, and mentors to their nephews. Milardo's work makes visible the multiple and diverse ways in which extended family members are concerned for and committed to the next generation.

Other topics that fit well under the umbrella of research on extended families can be found in literatures that are not designated as research on extended families but can be considered as such. "Fictive kin" and "chosen families" are examples. "Fictive kin," often discussed in the literature on African-American families, refers to family-like relationships that coexist with biologically and legally related family networks and can be vital sources of affiliation and support. "Chosen families" usually refers to the voluntary kin networks formed by gay and lesbian individuals. These literatures could be better integrated with research on extended families.

It is likely that a greater scholarly focus on cousins, aunts, uncles, nieces, nephews, godparents,

ex-relatives, fictive kin, and chosen families would reveal realms that are both interesting and meaningful to our knowledge about extended families. Although the breadth of extended family relationships has been overlooked, the research that exists suggests that this is a fruitful avenue for future research in the area of personal relationships.

EXTRADYNAMIC SEX

Extradynamic refers to a wide range of behaviors occurring outside of a committed relationship. Most research focuses on vaginal sex occurring outside of a marital relationship. However, behaviors can range from intense emotional relationships or close friendships, to kissing, oral sex, or other sexual behaviors, and the primary dyad need not be married. Extradynamic behavior that takes place

on the Internet is a burgeoning area of research, focusing on individuals who engage in secretive, often sexually charged interactions with others online. Extradyadic relationships are often characterized as emotional or sexual in nature. Emotional relationships involve an intense friendship or romantic bond, but lack a physical or sexual component. Sexual relationships are considered to be purely physical, without emotional connection or commitment. Some researchers have suggested that infidelity more often exists on a continuum of sexual and emotional involvement.

A distinguishing feature of infidelity is that it occurs without the awareness or sanction of one's partner. If both partners are aware of and consent to extradyadic activities, such an arrangement would be considered an open marriage or relationship; these types of relationships are more common among gay men but do also occur among heterosexual couples and lesbians. Unless otherwise stated, extradyadic sexual intercourse among heterosexual and same-sex couples, not condoned by both members of the primary dyad, is the focus of the current entry. *Infidelity*, *extramarital sex*, *extrarelational sex*, *affairs*, *cheating*, and *adultery* are other terms used to describe this type of extradyadic sex. In this entry, the prevalence of and attitudes toward infidelity will be described as will decisions about ending affairs, followed by correlates of infidelity and emotional and relationship outcomes. Finally, therapeutic implications and methodological issues are discussed.

Prevalence

Studies of infidelity among heterosexuals conducted during the past several decades suggest that between 20 and 40 percent of men and between 20 and 25 percent of women have ever engaged in extramarital affairs. In one study, 45.2 percent of gay men who indicated that they were in committed, monogamous relationships reported that they or their partner had sex with a third party since the beginning of their relationship. Data from national, representative samples, however, such as the 1994 General Social Survey and the National Health and Social Life Survey, suggest lower rates of infidelity. Specifically, data from national surveys indicate 23 to 25 percent of

men and 12 to 15 percent of women have ever engaged in extramarital sex, with between 1 and 4 percent doing so in the past year.

Attitudes Toward Infidelity

Results suggest that attitudes toward infidelity are most often negative, although men report more favorable attitudes than do women. Men and women typically evaluate infidelity in committed dating relationships less negatively than infidelity occurring among married couples. Some research suggests that women are more accepting of sexual infidelity than of emotional infidelity, and men are more accepting of emotional infidelity than of sexual infidelity. In general, however, emotional infidelity is more accepted than sexual infidelity is.

Correlates of Infidelity

Much of the infidelity research has focused on correlates of transgressing behaviors. The most widely cited predictors and correlates of infidelity can be broken down into three subcategories: demographic factors, interpersonal factors, and individual factors. However, study results vary widely; as a result, clear predictors of infidelity are difficult to determine.

Demographic Factors

Gender is the most commonly studied demographic factor. Gender is so critical in infidelity research that most researchers separate men and women in their analyses. Findings generally suggest that gay and heterosexual men are more likely to engage in infidelity and have more extradyadic partners than are women. However, when extradyadic behaviors other than sexual intercourse are considered (e.g., maintaining an intimate emotional relationship or engaging in other extradyadic sexual behaviors), women report engaging in as many or more acts of infidelity than do men. Generally, men who engage in infidelity are motivated by sexual factors and women are more emotionally motivated.

Research on marital status suggests that married individuals are less likely to be unfaithful than are those who are cohabiting or dating. Perhaps

level of commitment in a marriage relationship confers some protective benefit. Individuals who have had a divorce are more likely to have engaged in infidelity.

Race is also commonly included in correlational studies of infidelity, although the relationship between race and infidelity is not consistent. Infidelity appears to be more common among African-American persons, and particularly African-American men, than among other ethnic groups.

Religiosity is another demographic variable that is widely cited as a predictor or correlate of infidelity. Virtually all religious groups condemn extradyadic relationships and hold fidelity as a strong core belief. Infidelity is reported more often by individuals who endorse no religious affiliation than by those who endorse a religious affiliation. The interconnected nature of religious communities may decrease opportunities for infidelity and suggest to individuals that they are likely to be caught—two factors that may lessen motivation to be unfaithful.

Higher levels of completed education are often concomitant with more accepting attitudes about infidelity, but the relationship between education and extradyadic sexual behaviors is less consistent. Several studies have found that well-educated persons are more likely to engage in infidelity than are individuals with lower education levels. However, other studies have found the reverse, or no relationship at all. It is likely that the relationship between education and infidelity is a complex one, influenced by other factors.

Several demographic factors, such as employment, income, and rural versus urban residence, are thought to increase infidelity by providing individuals with greater opportunity to meet potential partners. Studies of couples or individuals in therapy suggest that 46 percent to 62 percent of persons who had engaged in extrarelatinal sex reported meeting their extradyadic partner through their workplace. Also, higher income levels can defray costs associated with infidelity and provide more opportunities to engage in extradyadic relations. Nonetheless, a number of empirical studies have not found a relationship between employment, income, and infidelity, and some find a relationship for men but not women. Results indicate that individuals who live in urban settings are more likely to engage in extradyadic relations than are those who live in rural areas. This could be

attributed to a greater number of available partners in urban settings, as well as to a potentially lowered risk of discovery.

Interpersonal Factors

A variety of interpersonal factors increase the probability of being unfaithful. The strong expectation of fidelity in monogamous relationships levies high costs for being caught engaging in extradyadic relations. However, if the quality of the relationship is low, there is less to be lost as a result of infidelity. The interpersonal factor that best predicts infidelity in monogamous relationships is a lack of satisfaction in the primary relationship. In one study of gay men, participants in committed, monogamous relationships who reported that they, or their partner, had engaged in sex with someone else since the beginning of their relationship scored lower on measures of relationship quality and satisfaction than do men who maintained faithful monogamous relationships and men who had agreements with their partner to be sexually nonexclusive. Additionally, men and women who are sexually dissatisfied in their primary relationship are more likely to be unfaithful than are those who report sexual satisfaction, although sexual dissatisfaction plays a larger role for men than for women.

A number of other relationship factors have been found to put couples at risk for infidelity. For example, boredom, low levels of commitment, and higher levels of conflict in the primary relationship are associated with infidelity in both men and women. Perceived inequity also affects the likelihood of engaging in extradyadic sex, particularly among women.

Personal peer groups may also play a role in infidelity, especially for men. Individuals involved with a peer group where the prevalence and acceptance of infidelity is high are more likely to engage in infidelity themselves. Conversely, if there is a greater chance that members of a shared peer group will find out about extradyadic relations, men and women are less likely to engage in such behaviors.

Individual Factors

Personality attributes such as extraversion, low agreeableness, high neuroticism, low conscientiousness, and high psychoticism all contribute to

a greater likelihood of engaging in extradyadic relations. Likewise, individuals who emphasize independence from their primary partner, those who feel a need for variety in their relationship, and those who feel insecure in their primary relationship all show higher incidences of engaging in infidelity. Men who feel a sense of powerlessness, meaninglessness, or social isolation tend to engage in more infidelity.

Psychological problems may also play a role in engaging in infidelity. In particular, individuals with low self-esteem or depression may be more likely to have extradyadic sex. However, one non-clinical study found that men who engaged in infidelity actually had higher self-esteem than did those who did not, and men and women who engaged in infidelity self-rated their attractiveness higher than did those who did not engage in infidelity. Additionally, those with substance abuse problems are more likely to engage in extradyadic relations. Notably, many results in this body of literature have not been replicated in community samples and may only apply to those with clinical levels of depression or substance abuse.

Permissive sexual values and attitudes have consistently been associated with infidelity. Not surprisingly, those who are more open to the idea of extradyadic relations are more likely to engage in such behaviors. Some research suggests that "personal readiness" to engage in infidelity is a salient predictor of being unfaithful.

If an individual has less sexual opportunity, it is more difficult for them to become extradyadically involved. Individuals who have had more sexual opportunity in the past, such as those reporting a higher number of prior sexual partners, have been shown in some research to be more likely to engage in infidelity, although this is not a consistent finding.

Decisions to End an Affair

Although some cases of infidelity are one-time occurrences, others may be recurring and persist for many years. The decision to end an extradyadic relationship can be made by the individual having the affair, his or her primary partner, or by the extradyadic partner. A number of factors affect the decision to end an affair. Women with

positive attitudes toward sex tend to carry on their extradyadic sexual relationships for longer periods. Men and women typically consider the rewards and costs of engaging in an extradyadic relationship: If the rewards of the relationship outweigh the costs of ending it, the relationship will persist until the opposite is true.

Emotional Responses to Infidelity

Infidelity evokes many emotions in both the betrayed partner and the partner that engaged in extradyadic activity, and many of these emotions, surprisingly, overlap. These may include symptoms of post-traumatic stress disorder, for example, disturbed sleep, irritability or anger outbursts, difficulty concentrating, hypervigilance, and recurrent intrusive thoughts about the affair. However, emotional responses may vary depending on the type of infidelity. Both women and men have been found to react to sexual infidelity with anger and blame but react to emotional infidelity with more hurt feelings. Where many studies have shown men and women to react similarly to a partner's infidelity, some other research suggests women experience more emotional distress over all types of infidelity than men do.

Emotional responses to the initial disclosure of infidelity are usually intense. At the initial disclosure, powerful emotion is expressed through confrontation with the offending partner. However, some research shows a time lapse between the initial discovery and the expression of intense emotions. These emotions include, but are not limited to, insecurity, helplessness, abandonment, depression, and a desire for vengeance.

Once the intense emotional response passes, most individuals go through a time of making meaning of the event, evidenced by less emotional reactivity. This is often when crucial decisions about the future of the relationship are made.

Much research has focused on the jealous reactions men and women experience in response to various types of infidelity. Traditionally, among heterosexuals, men have been found to react with more jealousy when their partners have transgressed sexually, whereas women have been found to react with more jealousy to a partner's emotional transgressions. Further, heterosexual men

and women report less intense jealousy to a partner's same-sex infidelity than to infidelity with an opposite-sex partner.

Research on jealousy in response to infidelity in same-sex couples has been mixed. In one study conducted in the mid-1990s, lesbian women reacted similarly to infidelity as their heterosexual counterparts, but gay men were found more often to react with distress to emotional infidelity than did heterosexual men. Study authors Michael Bailey and his colleagues suggested this is because homosexual men have a much higher tolerance for sexual jealousy than heterosexual men do, making emotional infidelity the more upsetting event. A second, more recent study, however, found lesbian women resembled heterosexual men (more jealous of sexual transgressions) and gay men resembled heterosexual women (more jealous of emotional transgressions). More research is needed to understand how jealousy resulting from different types of infidelity is manifested in same-sex relationships.

Relationship Outcomes

After an affair, the fate of the primary couple's relationship depends on a number of factors. If the bond between the core couple is stronger than the bond between the extradynamic couple, it is more likely that the primary relationship will prevail. Also, the circumstance surrounding the extradynamic activity, for example who the extradynamic partner is and where the affair took place, can affect whether the primary relationship succeeds or fails. The extent to which the betrayed partner is willing to forgive the transgressor affects whether the primary relationship can continue and at what level it will function.

Jennifer Schneider found that 60 percent of the participants planned to leave their primary relationship once infidelity was disclosed, but less than 25 percent of those couples actually did so. Other research has found that in a large number of infidelity cases, the couple stays together but the relationship quality remains poor.

Infidelity spawns, and occurs in response to, a variety of relationship issues. If a couple is unable to work through these issues, or one individual is not open to rebuilding the trust in the relationship, the relationship may dissolve. Among married

couples, infidelity independently predicts divorce. Men are more likely to end their relationship if their female partners were sexually unfaithful. Women, on the other hand, are more likely to end their relationship over emotional infidelity.

Some couples are able to keep their relationships intact after an extradynamic involvement. Research suggests that a subset of couples actually experience positive relationship outcomes after infidelity. These couples are often better able to communicate about the affair and work through their differences, either on their own or with the help of a therapist.

Therapeutic Implications

Infidelity often leads a couple to seek relationship counseling. Couples therapists report infidelity is one of the most difficult relationship problems to treat. Couples seeking therapy after an affair are often more distressed at the start of treatment than are couples in therapy for other issues. Therapists and clients have a number of important tasks to accomplish in therapy: gaining an understanding of why the affair occurred, expressing emotions, achieving forgiveness, and rebuilding trust. To reduce long-term resentment and hostility, it is critical that the betrayed spouse have the opportunity to express his or her feelings. Couples may also benefit from working on wider relationship issues, rather than focusing solely on the affair. There is limited research on the efficacy of couples therapy specific to couples who have experienced infidelity, and studies that have been conducted are based on small samples. Nonetheless, studies typically show improvement in couples functioning after broad-based couples counseling.

Counselors working with couples on issues related to extradynamic sex must take the relationship context into account. Sex outside of a dyadic relationship is not, by nature, harmful if couples have agreed upon and feel comfortable with non-monogamy. This is most common among gay male couples, but does occur in heterosexual and lesbian couples as well. Therapists working with same-sex and opposite-sex couples will often use similar approaches; however, it is particularly important that practitioners consider unique cultural and relationship norms when evaluating the

meaning and impact of the secondary sexual or emotional relationship.

Methodological Issues

Research on infidelity is plagued by a number of methodological issues that lead to inconsistencies in findings. Because of the taboo nature of extradyadic sexual behavior, social desirability is a serious obstacle to obtaining honest information related to incidence of infidelity. Mark Whisman and Douglas Snyder found that women were more likely to report being unfaithful when completing a computer-assisted survey than when directly interviewed by a researcher. As well, infidelity lacks a consistent operational definition, so comparing across studies can be difficult. Most research on infidelity is based on small, geographically limited samples of primarily Caucasian individuals. A large subset of this research is conducted on university student participants, who most often have not been married, posing a challenge to generalizability. Further, most researchers use cross-sectional designs. Because of this, it is difficult to discern whether relationship problems or other correlates of infidelity predated the transgression or occurred as a result. Finally, little is known about infidelity in cohabiting and lesbian couples. Future research is needed with samples that are more diverse in sexual orientation, marital status, socioeconomic status, and ethnicity.

EXTRAVERSION AND INTROVERSION

Extraversion is a broad trait that encompasses many distinct but related facets. A variety of characteristics, including positive affectivity, gregariousness, warmth, impulsivity, assertiveness, activity level, and the tendency to seek excitement have all been incorporated at one point or another into different models of the trait. Extraversion is important for the study of relationships because all of its features are linked with social activity. For some facets, such as gregariousness, assertiveness, and warmth, these links are quite direct—the characteristics explicitly involve interactions with others. With other facets, such as impulsivity, activity-level, excitement-seeking, and positive emotions, the links are more indirect—people who have these characteristics tend to enact them in situations involving other

people. Thus, extraversion is potentially one of the most relevant personality characteristics for the study of human relationships. This entry discusses the history of the trait, the processes that underlie it, and the relationship outcomes that are most strongly associated with it.

History

Extraversion is one of the most studied traits in personality psychology. Although it is sometimes described using terms other than *extraversion* (including *confident self-expression*, *surgency*, *assertiveness*, *power*, or its antonym *introversion*), some form of this trait has been included in almost all comprehensive models of personality. For instance, many personality psychologists believe that five broad dimensions (the so-called Big Five model of personality) subsume the many narrow characteristics that exist and that have been studied by psychologists. The five traits include Extraversion, Neuroticism, Agreeableness, Conscientiousness, and Openness to new experience. These Big Five dimensions have been identified through factor analysis of lists of trait-descriptive adjectives and questionnaire items. They have also emerged in cross-cultural and cross-language investigations. The fact that an extraversion-like trait emerges in most if not all analyses provides strong evidence of its robustness and importance as a personality trait.

Extraversion is also usually found in other trait models that were identified using alternative techniques. For instance, extraversion is one of three major traits (along with neuroticism and psychoticism) in Hans Eysenck's influential model, which was developed using a combination of theoretical and factor analytic work. In addition, extraversion is conceptually similar to positive emotionality, one of three major traits (along with negative emotionality and constraint) in Auke Tellegen's model.

Processes Underlying Extraversion

A number of process models have been developed to explain individual differences in extraversion, though no consensus has been reached regarding which of these models is correct. Some of the earliest models traced individual differences in

extraversion to differences in basic learning processes. Eysenck initially believed that extraverts conditioned (or learned new associations) slowly and got bored with repetitive tasks quickly. In turn, these basic underlying learning processes led to distinct behavioral outcomes—extraverts' poor conditioning was thought to manifest in poorer socialization (compared with introverts) along with a desire for constantly changing stimuli.

After further research, Eysenck modified this early model to focus on arousal as the key individual difference that underlies extraversion, with extraverts having lower resting levels of arousal and less susceptibility to becoming aroused than introverts have. Because arousal is thought to have an inverted-U-shaped association with performance and subjective enjoyment, moderate levels of arousal tend to be optimal. Arousal levels that are either too high or too low are detrimental to performance and enjoyment. According to this model, the chronic under-arousal of extraverts leads them to seek out situations with high levels of stimulation, thereby moving their own characteristically low arousal closer to an optimal moderate level. These arousing situations often involve other people, which is what makes extraverts appear to be sociable. Introverts, on the other hand, were thought to be chronically over-aroused, which leads them to avoid stimulating social situations—such as parties and other social interactions—that could increase their arousal even more.

Although research on Eysenck's theory continues, modern theories of extraversion tend to focus less on arousal and more on individual differences in positive affect, reward-sensitivity, and dopamine systems in the brain as underlying causal mechanisms. For instance, Jeffrey Gray presented a revised version of Eysenck's original model, arguing that the basic dimensions of extraversion and neuroticism reflected combinations of two more fundamental dimensions: individual differences in the tendency to approach rewards and in the tendency to inhibit responses in the presence of punishment. The former characteristic—which Gray believes is more strongly associated with extraversion than is the latter—was linked to an underlying physiological system termed the *behavioral activation system*. Gray posited that individuals with sensitive behavioral activation systems would learn better when rewarded for good behavior than

when punished for bad behavior. In addition, individuals with strong behavioral activation systems are thought to be more motivated to approach and pursue rewards. As with the inhibition and cortical arousal models that came before it, the reward-sensitivity model posits that social activity is a somewhat indirect outcome of this more basic underlying process.

Reward-sensitivity theories also link extraversion with dopamine and dopamine systems in the brain. Dopamine is a neurotransmitter that has been associated with so-called pleasure centers in the brain. Dopamine appears to be involved in the psychophysiological reactions to rewards and especially in the motivation to approach rewards.

Additional researchers have built on the idea of reward-sensitivity to focus on underlying individual differences in positive affect. It is thought that one mechanism by which the motivational component of reward systems work is through the feelings of energy and excitement that are associated with positive affect. Those who are approaching a reward will experience these feelings, and those whose reward systems are quite sensitive will experience positive affect to a greater degree than will those whose reward systems are less sensitive. For instance, spending time with others might be rewarding to most people, and therefore, people would feel a sense of excitement and positive anticipation when they knew such social interactions were potentially available. These feelings of excitement and anticipation might actually motivate people to approach the social situations, and those who experienced these emotions more strongly might go to greater lengths to make sure that these interactions occurred. Some believe that these individual differences in positive affect are the central features of the extraversion dimension. Much current research on extraversion is devoted to identifying which of these underlying process models is correct.

Correlates and Outcomes of Extraversion

As one of the most studied personality traits, extraversion has been linked with a wide variety of correlates and outcomes. One of the most robust findings is the correlation between extraversion and subjective well-being (otherwise

known as “happiness”). Research consistently shows that extraversion is (along with low levels of neuroticism) one of the strongest correlates of happiness and related constructs. Extraverts are particularly likely to experience high levels of positive emotions such as joy and excitement. Interestingly, even though extraverts are particularly likely to experience high levels of these positive emotions, they are not necessarily any less likely than are introverts to experience negative emotions such as anxiety, sadness, and fear (characteristics that tend to be better predicted from neuroticism). This is because positive and negative emotions are relatively independent from each other. These findings linking extraversion to well-being variables have been replicated frequently using a variety of self-report and non-self-report methods.

Extraverts tend to engage in more social activity than do introverts. For instance, numerous studies have compared self-reports or informant-reports of extraversion to measures of social activity collected using experience sampling techniques. In these studies, participants are asked to describe their current activities multiple times per day using handheld computers or paper-and-pencil questionnaires. Although correlations between extraversion and social activity variables tend to be somewhat smaller than some might expect, they are robust. These studies consistently show that extraversion is associated with increased time spent in social situations, particularly in social situations involving friends and family members.

Extraversion has also been linked to the *quality* of social relationship outcomes. For instance, Daniel Ozer and Veronica Benet-Martinez reviewed the literature on the personality predictors of interpersonal outcomes and found that extraversion (along with agreeableness) predicted peer acceptance, friendship, and popularity among children and adolescents. In addition, the quality of children's relationships with their parents was associated with extraversion. Ozer and Benet-Martinez noted that fewer studies had examined the links between personality variables and adult peer relationships, but those that had been conducted supported the idea that extraversion is an important characteristic.

Extraversion does not appear to be a particularly important predictor of romantic relationships, however. Several meta-analyses have

summarized the links between personality traits and romantic relationship outcomes, and these studies show that in comparison with such traits as agreeableness, neuroticism, and even conscientiousness, extraversion tends to be a weaker predictor of romantic relationship variables including marital stability and relationship satisfaction. This may be because in most models of the trait, surgency, confidence, and assertiveness are emphasized rather than warmth and empathy. These characteristics may promote popularity and the ability to confidently interact with (and perhaps even dominate) others, but they may not improve the quality of romantic and other close relationships. Instead, the lack of hostility that is associated with high levels of agreeableness and low levels of neuroticism might play a more important role in these close relationship outcomes. Extraversion may reflect a general interest in social activity and confidence with such activity rather than a general tendency to be warm, empathic, and supportive.

Future Directions

Future research on extraversion faces at least two clear challenges. One is to identify the processes that underlie this trait. More than perhaps any other personality trait (with the possible exception of neuroticism), extraversion has been linked to specific psychophysiological systems. However, multiple underlying systems have been proposed. Future work must clarify which of these systems are most important and how the underlying processes that occur within these systems lead to the external, behavioral manifestations of extraversion typically associated with the trait. Research into these underlying processes will also help clarify why the various characteristics that are subsumed under the broad trait of extraversion (including such characteristics as gregariousness, assertiveness, high activity levels, and high levels of positive emotions) are linked and which is most central.

In addition, future research must clarify the real-world outcomes of extraversion. The research reviewed earlier shows that extraverts do engage in

more social activity than introverts do and that extraverts appear to have more success in peer relationships. But future research can go further in identifying the real-world outcomes that extraversion fosters. For instance, most of what we know about the outcomes of extraversion concerns sociability and social relationships. But if the underlying individual difference that drives extraverted behavior is not a desire to be sociable, but individual differences in sensitivity to rewards, then outcomes related to this difference might be closely linked to extraversion. For instance, dopamine has been linked to the processes involved in drug addiction, and if extraversion is related to these underlying systems, then extraversion may play an important role in these real-world outcomes, too. Extraversion is associated with many positive outcomes including greater happiness, but more work is needed to understand the full range of outcomes that exist, along with the processes by which this important personality trait leads to these outcomes.

FACEWORK

If you have ever given a presentation and you forgot what you were going to say, dropped your notes, or stumbled as you began to move across the room, you know what it means to lose “face.” You were embarrassed because you were not performing as a competent public speaker. This is a common scenario that comes to mind when people think about losing face. However, consider occasions when you might have dressed inappropriately for an event, lost your temper or cried in public, said something rude and hurtful to a friend, asked someone out on a date but were rejected, or even cheated on a romantic partner who trusted you. In these instances as well, you lost face. This entry defines the concept of face and discusses the ways people maintain or restore face through facework.

The realization that a person’s competent and moral “self” is to some degree a social construction dates back to ancient Chinese philosophers. However, Erving Goffman was the first contemporary writer to present a coherent theory of face and facework during the 1950s and 1960s. Goffman considered *face* to be the public image we present to others during interaction. We construct this image based on our understanding of the social norms for expected and appropriate behavior. For example, in some situations, we may emphasize that we are witty or funny, in other situations that we are intelligent, and in other situations when a friend is distressed that we are compassionate and

supportive. *Facework* includes the range of communicative strategies we use to maintain face. This is a two-directional process. That is, the process involves the efforts we expend to construct and maintain our own face as well as the efforts we expend to maintain the face of others and that we expect others to expend toward maintaining our face as well. If people did not cooperate to maintain their own and others’ face, interaction would become chaotic; the norms that guide interactions are predicated on the assumption that people respect their own and others’ face. In fact, Goffman used the term *shameless* to refer to people who consistently act inappropriately in public and seem to feel no embarrassment. He used the term *heartless* to refer to people who can watch others lose face and feel no compassion.

Goffman illustrated concepts of face and facework with a theatrical metaphor. Much as actors have a backstage where they prepare for performance on a front stage, ordinary people have a backstage (e.g., their home or office) where they prepare for their performance in public. While on front stage, we are expected to perform appropriately by successfully managing our props, lines, and costumes—that is, not spilling our coffee, not tripping on the sidewalk, not referring to people by the wrong name, not wearing our gym clothes out to dinner. We are expected to display positive emotions (even when sometimes not genuinely felt) and to moderate displays of negative emotions (control our anger toward others). In Goffman’s sense, the people with whom we interact serve as the audience for our performance when we are on front

stage. Indeed, even though we generally consider our home to be the backstage, we also realize that it is necessary on occasion to leave the stress of the day outside and construct a more relaxed face as we enter. We can certainly be more informal at home and social settings with friends, but many of the expectations for constructing an appropriate face or image still apply.

The facework that people do to support their own performance or the performances of others is typically uneventful and routine. However, sometimes people become more conscious of face loss and more actively engage in facework. The two general types of facework are preventive and corrective.

Preventive facework is performed when we anticipate that we might threaten our own or someone else's face. For example, the use of disclaimers such as "I may be wrong, but," "this might be a stupid idea, but," or "I know this might upset you, but" tell a listener that we recognize our comments may reflect on our competence or our sensitivity to the needs of others. Even the dreaded question, "does this make me look fat?" forces us to find a gracious way to soften the potential criticism (threat to other's face) by saying something such as, "Well, I think the other outfit is more flattering."

Corrective facework is performed after face has been threatened or lost. If the incident is relatively minor, then simple expressions such as "Excuse me" or "I'm sorry" will suffice. However, when the incident is more serious, a sequence of four interaction "moves" known as the remedial interchange may be necessary to restore face. First, a *challenge* is made that calls attention to the face-threatening act. The challenge may be implied or explicit. For example, if you are supposed to meet a friend for dinner at a local restaurant at 6:30, but you do not arrive until almost 7:00, your friend may look you with the expression, "You better have a good excuse" or may be more direct by saying, "You're late; what happened?" Both of these actions function as a challenge. Second, as the offending person, you make an *offering* that shows you are aware of and sorry about being late. Offerings typically include apologies, excuses (explaining extenuating circumstances), and justifications (attempts to minimize the severity of the action). So you might first apologize and make an excuse ("Sorry. I got held up at work and had to stop by the bank to get some money."). Or, you might apologize and offer a

justification ("Sorry. I know I'm a little late, but it's Friday and we can take our time."). Assuming that the offering is acceptable, the offended person gives an *acceptance* and the offending person closes the exchange with an *appreciation* or *thanks*. In our example, your friend might say, "No problem, I've been reading the menu and watching that interesting couple over there" and you would reply, "Thanks, I'm starved."

Research subsequent to Goffman's early writing has identified additional types of remedial actions that people do to restore face. This research indicates that in addition to apologies, excuses, and justifications, people sometimes use *remediation*, which physically corrects the situation (e.g., cleaning up a spilled soft drink or picking up dropped items). Other people often do this for the person who has lost face. In addition, people who have lost face or observed others lose face employ *humor* to alleviate the tension (e.g., "I'm such a klutz" or "Way to go, Grace"). Finally, two different strategies include *avoidance* (e.g., ignoring a behavior or action so as not to draw attention to it) or *aggressive actions* (e.g., insult, criticism, or retaliation). Aggression is not generally a useful strategy but is sometimes used to get back at a person who has intentionally damaged another's face, to assert power, or to teach someone a lesson so the incident doesn't happen again.

In sum, facework is a routine aspect of daily life. We tend to take it for granted until we feel the sting of embarrassment and realize that we have lost face. Fortunately, the cooperative efforts of others usually help us restore face and continue the interaction.

FACIAL EXPRESSIONS

Facial expressions are one channel of nonverbal communication. Facial expressions can function as paralinguistic signals—such as when one raises one or both eyebrows to signal a question—but most frequently have been studied as a means to express emotions. Emotional facial expressions are an important source of information that frequently dominates information derived from other nonverbal channels such as posture or tone of voice. In relationships, facial expressions often play an important role. For example, smiling is an important signal for affiliation, and the absence of smiles in marital conflict can escalate conflict.

The study of facial expression has been characterized by a number of controversies. This entry provides a brief summary of the current state of the literature and outlines the important roles facial expressions play in human interaction.

The first person to systematically study and describe facial expressions and their possible meaning was Charles Darwin in his book *On the Expression of the Emotions in Man and Animals*, published in 1872. He considered facial expressions to be both directly useful for the organism (e.g., the eyes are wide open in fear to facilitate information uptake), and an important source of information for others by alerting them to the intentions of the expresser (e.g., bared teeth in an angry dog signal an intention to fight).

Darwin considered facial expressions as evolved, and he necessarily assumed clear parallels and antecedents to human emotions in the emotions of animals and presumed human emotion expressions to be universal. Research in the early 20th century, however, failed to find a systematic link between emotional states and facial expressions. The contradictory research findings led Jerome Bruner and Renato Tagiuri to conclude in 1954 that there was little clear evidence for the recognizability of emotional expressions. This view remained basically unchanged until 1972 when Paul Ekman, Wallace Friesen, and Phoebe Ellsworth wrote a book to explicitly vindicate Darwin. They revisited the early literature and noted methodological problems with most failures to support Darwin's contentions. Based on this and some of their own findings, they concluded that emotional

expressions are indeed universal and directly associated with underlying emotional states. In the following decades, the notion that at least so-called basic emotions are universally expressed and recognized was largely accepted. However, the question of what emotional facial expressions actually express and whether they do so universally is still strongly disputed.

What Do Facial Expressions Express?

Three main theories have been proposed: Facial expressions express emotion, facial expressions express intentions, and facial expressions express the outcome of appraisals. The principal support for the notion that facial expressions express emotions stems from the fact that emotional facial expressions are generally well recognized. That is, when shown posed facial expressions—at least those corresponding to the so-called basic emotions of happiness, anger, fear, sadness, disgust, surprise, and possibly contempt—individuals are able to identify the corresponding emotional state at high rates of agreement and accuracy. The assumption here is that people recognize these expressions because they have associated events where people feel these emotions with these expressions.

However, when individuals are in a situation where they either report experiencing a certain emotion or that is highly likely to evoke a specific emotion, these same expressions have not systematically been observed. The fact that individuals who experience a specific emotion often do not show the prototypical facial expression that is usually recognized as signaling this emotion but, rather, a variety of—often quite weak and ambiguous—expressions, has been explained as an outcome of social norms. These “display rules” can override the innate expressions (Ekman's Neurocultural Theory) by attenuating them or replacing them with socially demanded ones.

A contrasting view regarding the source of facial expressions maintains that facial displays do not express emotions but, rather, social motives, such as a desire to affiliate or to withdraw (Alan Fridlund's Behavioral Ecology Theory). Evidence for this notion was provided in form of experiments showing that facial expressivity varies as a

function of social context. For example, smile intensity varies as a function of the presence of others, which in turn influences the expressers' motivation to share their amusement, a motive that is presumed to be stronger in a more sociable context. Later research showed that these functions are not necessarily mutually exclusive and that facial expressions vary as a function of both emotional state and social motives.

One conceptual challenge, however, posed by Fridlund's critique remained unresolved. He argued that given the rapidity of facial expressions, an emotion program that started in response to an emotion elicitor could not be successfully interrupted by a social norm, which replaces the emotion expression output of the program with a socially demanded expression. This issue is potentially amenable to resolution by recourse to appraisal theories of emotion. These theories predict that facial expressions are not first produced by an emotion-eliciting process and then filtered or modified by a social-rule-driven process. Rather, the social norms and motives—to the degree that they are endorsed by the individual—are an inherent part of the emotion elicitation process. Thus, using an appraisal framework, one can reconcile both the signal and symptom functions of emotions. That is, appraisal theories consider emotions as inherently determined by the organisms' motivational state and, hence, their intentions; therefore emotion expression by its very nature should express intentions because these are part of emotions in a fundamental way.

More specifically, some appraisal theorists have proposed that emotional facial expressions do not express emotions as a unitary state, but instead are directly related to individual appraisals. For example, the drawing together of the eyebrows in a frown is an output of an appraisal of goal obstruction. As appraisals proceed, a full-blown facial expression emerges as the sum output of the appraisals.

Are Emotional Facial Expressions Universally Recognized?

Since first posed by Darwin, this question has consistently been an important but divisive focus of the work on facial expressions. On one hand, a

considerable body of research supports the conclusion that the expression of emotion is largely universal, for example, through the mutual recognition of emotional signals across many cultures and across species boundaries. Thus, chimpanzees and dogs can recognize human emotion displays, and humans can recognize chimpanzee and dog emotion displays. Yet, the research on cross-cultural recognition has been heavily criticized on methodological grounds. This view also contrasts with perspectives that consider emotional behavior as determined completely by verbally transmitted cultural norms and rules. Thus, social constructivist approaches to emotion emphasize differences in emotion vocabularies across cultures and dispute universality of expression or recognition on these grounds.

Most contemporary psychologists now favor an interactionist perspective in which both innate and cultural factors play some role. More recently, strong meta-analytical evidence for this intermediate view has emerged and led to the formulation of Hillary Elfenbein and Nalini Ambady's Dialect Theory. They argue that the universal language of emotion expression has local dialects that differ subtly from each other. Consistent with an appraisal approach to emotional expressions, dialects could be explained by postulating subtle differences in appraisal patterns resulting from differences in cultural constraints, values, and norms that reflect themselves as differences in facial expression.

Social Context and Facial Expression

Facial expressions are usually shown in the context of social interactions, and hence, it should not be surprising that they depend to some degree on the relationship between interaction partners. Facial expressions tend, for example, to be more intense when shown in the presence of friends than strangers. The relative status of the interactants also affects facial displays. For example, higher-status individuals show clearer, more easily decodable expressions. One hypothesis is that high status individuals are less bound by social rules and norms and, hence, have more leeway to express what they feel clearly.

Further, the social group to which a person belongs influences the nature of that person's facial

expressions. Some of this is due to the different social rules and norms that apply to various social groups. Women, for example, are expected to smile more and in fact do smile more than do men. But there are other more subtle influences. Specifically, certain factors that covary with group membership, such as facial morphology or appearance, may lead decoders to interpret the same facial expressive movements quite differently depending on the specific nature of the face on which they are displayed. For example, the facial morphology of women and younger individuals appears to enhance the cues associated with happiness, whereas those of men and older individuals enhance those associated with anger. The facial morphology differences across racial groups also affect the clarity of cues associated with specific emotions. For example, the strong contrast between teeth and dark skin makes smiles more easily perceptible, whereas the eye fold of some Asian eyes obscures the widening of the eyes shown in fear.

Independent of the cues actually present on the face of another, the perceptions of these are going to be filtered through the goals, concerns, motivations, and stereotypes that individuals bring to an interaction. These factors may attract attention away from or toward the cues specifically linked to particular emotions. Thus, the belief that women are more likely to experience sadness tends to lead people to perceive more sadness in female than in male faces—even when the same androgynous face is simply rendered male or female by adding the corresponding hairstyle.

Facial Expression and Person Perception

Facial expressions express more than emotions. Specifically, facial expressions modulate perceptions of the personality dimensions. Thus, individuals who show anger or disgust are perceived as more dominant and those who show happiness or sadness as more affiliative. Facial expressions of anger have also been linked to perceptions of competence (at least for men) and toughness. By contrast, expressions of sadness suggest lack of competence and submissiveness. Smiling in turn leads to attributions of trustworthiness. Appraisal theories of emotion provide a theoretical rationale for the link of expression to person perception.

Specifically, facial expressions of emotion relate to the underlying appraisal. For example, showing anger rather than sadness when learning bad news suggests that person appraises the situation as potentially changeable rather than as irreversible and, hence, implies that the person has the required competence to deal with the problem.

Measurement of Facial Expressions

There are three primary means of measuring facial expressions. First, facial expressions can be shown to naïve judges who are asked to identify the mental state of the person. For expressions shown spontaneously by individuals in a social interaction, inter-rater reliability is usually only low to moderate and hence demands a relatively large number of judges to achieve acceptable levels of agreement. Also, judges tend to fatigue rapidly and can therefore only rate a limited number of expressions (probably not more than 100). This implies that the logistic requirements for this method can be prohibitive. Second, facial expressions can be measured by trained coders who use a descriptive coding system such as Ekman and Friesen's Facial Action Coding System (FACS). This system allows coders to categorize every possible facial movement based on the appearance changes associated with that movement and has the advantage of high reliability and precise information on the actual facial movements shown. More difficult is the task of assigning specific meaning to the facial patterning. This procedure is also fairly time consuming (1 minute of expressive behavior requires approximately 1 hour of coding time). Recent advances in computer coding of facial action units may eventually overcome this particular limitation of FACS. There are specific versions of FACS for the use with infants (whose faces wrinkle differently than adults' faces do) and chimpanzees, allowing for developmental and comparative studies using facial measurement. Finally, instead of measuring overt facial behavior, it is possible to use electromyography to measure the relevant facial muscle activity. This approach has the advantage of providing excellent time and space resolution, thus allowing for the measurement of subtle expressions that are not or are only barely visible (such as facial

mimicry reactions). The disadvantage is that only a limited number of muscles can be assessed at any one time. Also, it is not always easy to assign specific meaning to a specific muscle reaction. For example, Corrugator Supercilii activity occurs in sadness, in anger, and when concentrating. However, this problem can be solved by looking at patterns and constraining the experimental situation appropriately.

FAIRNESS IN RELATIONSHIPS

Romantic relationships are generally associated with love, trust, commitment, and caring for each other's needs and much less with issues of fairness or justice. In the past, most justice theorists have therefore typically considered justice and fairness—terms that are used interchangeably—as unimportant in close relationships. More recently, however, theories of fairness and justice have been increasingly applied to close relationships, and there is consensus that justice issues are important in close relationships. Fairness and justice refer to laws and formal rules that guide human behavior, but also to the ideas that people have about right and wrong, about how we should or ought to behave, and about what we are entitled to. As one of the first social justice researchers, J. Stacy Adams, addressed the fairness of the allocation of resources or outcomes, generally referred to as *distributive justice*. Later, John Thibaut and Laurens Walker argued that people's fairness judgments depend not only on the allocation of outcomes, but also on the procedures that precede the allocation of outcomes. This type of justice is referred to as *procedural justice*. This entry discusses the basic principles of distributive and procedural justice and how fairness affects close relationships.

Distributive and Procedural Justice

The three basic principles of distributive justice are *equity*, *equality*, and *need*. Equity theorists such as Elaine Hatfield and her colleagues were among the first to apply justice theories to the domain of close relationships. Equity exists when partners perceive the same ratio of inputs and outcomes as their partner, or in other words, when partners perceive an equal balance in their relative inputs and outcomes in the relationship. When partners perceive inequity in their relationship (i.e., when they feel overbenefited or underbenefited), they become distressed. Second, people feel a right to be treated equally with others who are like them. According to the equality principle, partners will feel satisfied in their relationship if each receives the same level of outcomes, regardless

of their inputs. This principle holds for the distribution of positive outcomes such as goods, benefits, and rewards as well as for negative outcomes such as costs, burdens, and duties. Finally, the need-based principle refers to the rule that resources and outcomes should be allocated on the basis of the partners' needs, regardless of the partners' inputs. Researchers such as Margaret Clark argue that the need-based rule of justice is the prevailing justice norm for close (or *communal*) relationships, as romantic partners are expected to be responsive to each other's needs, instead of keeping track of inputs and outcomes. Others have shown that exchange principles such as equity and equality also apply to close relationships, for example, when partners divide paid and unpaid (i.e., household) labor, exchange intimate behaviors (e.g., spending time together, sexual relations), and when they regard their overall contributions to the relationship.

Procedural justice entails both formal procedures such as laws and rules and informal procedures such as being treated with dignity and respect or having the opportunity to voice one's opinion. Research in organizational and experimental settings has shown that procedural justice affects human behavior, attitudes, satisfaction, and affective feelings. People are more satisfied with their relationship and more committed to a distribution of outcomes when they have been treated fairly than when they have been treated unfairly. This effect is commonly referred to as the *fair process effect*: People react more positively to outcomes or other events that follow from fair rather than unfair procedures. Procedural justice is enhanced by the opportunity to express one's views and opinions and the opportunity to present information relevant to the decision (i.e., *voice*). This effect is commonly referred to as the *voice effect*: Individuals perceive a procedure to be more fair and satisfying when they are granted voice than when they are not granted voice.

Fairness in Close Relationships

Research on fairness in close relationships has focused almost exclusively on distributive justice. This research has addressed the use of the equity, equality, and need-based rules. In addition, Melvin

Lerner's *justice-motive theory* has provided a different theoretical approach and proposes three basic schemas that are developed in early childhood: an identity schema (i.e., the other is the same as the self and identities are merged), a unit schema (i.e., the other is similar to the self and an equal interaction partner), and a non-unit schema (i.e., the other is different from the self and a competitor). Situational cues that are present in the interaction with a close other will determine which justice rule is appropriate, given a certain basic schema. Situational cues are vicarious dependency (i.e., partners largely depend on each other for attaining desired resources), convergent goals, and divergent goals. For example, partners who have recently married usually feel merged with each other (identity relation). When partners have to decide who will attend a school meeting, situational cues of vicarious dependency (e.g., one partner is not feeling well) will elicit feelings of caring and the other partner will decide to attend the school meeting (i.e., using a need-based rule). The same situation may lead to a different decision in a couple that is about to divorce (non-unit relation). The other partner may now apply the equity rule to determine whether both are doing their fair share in attending school meetings.

Individual differences and relationship norms matter also. For example, women tend to feel deprived in their relationship more often than men do. Bram Buunk and Nico van Yperen showed that both men and women perceive women to contribute more to their marriage in relational inputs (i.e., love, attention, accommodation) than do men and to receive fewer outcomes (i.e., interesting work, opportunities to meet others, freedom to do what one wants). Furthermore, individuals differ in whether they favor a communal orientation, in which they generally desire to give and receive benefits out of concern for others' needs, versus an exchange orientation, in which they generally seek direct reciprocity from others in benefits and demonstrations of affection. They will use justice norms accordingly.

Another area of research on distributive justice in close relationships has dealt with gender inequalities in various domains in close relationships, with the division of family labor (i.e., housework and childcare) standing out as the predominant area of research. Women do a much larger share of the

family work than men, regardless of their employment status, both in Western Europe and in the United States. Surprisingly, only a minority of women regards the division of labor as unfair. Apparently, mere gender inequality is not a sufficient condition of feelings of injustice. The *distributive justice framework* was developed by Brenda Major and Linda Thompson to understand this “paradoxical sense of contentment” with the unequal division of labor. It is a conceptual analysis of partners’ perceptions of fairness in the relationship that claims that fairness judgments are affected by people’s wants and values, comparison standards, and justifications.

Wants and values refer to the outcomes people desire or value. Fairness judgments depend on the individual’s aspirations, expectations, and desires. Individuals must value or want an outcome in order to feel inequitably treated or deprived if they do not have that outcome. Faye Crosby’s *two-factor model of relative deprivation* further states that feelings of injustice result from a combination of unfulfilled wants and feelings of entitlement or deservingness. Women will not feel deprived if their partner does not do his fair share in the household unless they *want* their partner to participate more in household tasks and feel that they are *entitled to* their partner’s help. Thus, wanting and feelings of entitlement are a necessary condition for feelings of deprivation or injustice. Gerold Mikula further adds that attributions of blame are basic elements of the experience of injustice. Women will regard the division of labor as more unjust when they blame their partner for not doing his fair share.

Comparison standards refer to the standards people use to judge their outcomes. Feelings of injustice depend on the outcome of a social comparison process. For example, partners compare their own inputs and outcomes with those of their partner. Consistent with Equity Theory, partners who perceive inequity in the division of labor will feel distressed. Buunk and van Yperen labeled this type of social comparison with the partner as *relational comparison*. In line with Social Comparison Theory, partners also compare their inputs and outcomes in the relationship with those of similar others in a reference group—family members, friends, and acquaintances of the same gender. This type of comparison with similar others is

referred to as *referential comparison*. Because people generally tend to make downward comparisons with regard to their close relationships (i.e., people generally tend to view their own relationship as better than other people’s relationships), women tend to perceive more fairness in their own relationship than in the relationships of other women. This adds to the explanation of the paradoxical sense of contentment with the unequal division of labor.

Justifications refer to procedures, attributions, or rules that legitimize a given outcome. Women can justify an unequal division of labor (or a negative outcome) when they believe that the outcome resulted from the application of a fair procedure. As mentioned in the introduction of this entry, the literature on procedural justice has shown that people judge the same outcome as more fair under conditions of high procedural fairness than under conditions of low procedural fairness. Research has shown that women perceive the division of labor as more fair when they have had a voice during relationship conflict over the division of labor.

Little is known about the role of procedural justice in close relationships, even though it has been argued in the social justice literature that procedural justice generally has great consequences for the way people react to (in)justice. These consequences often have more impact than do those of distributive justice. It could well be argued that procedural justice has strong effects on partners’ reactions toward injustice in close relationships. Tom Tyler and Alan Lind have argued that relational motives shape procedural justice judgments. Their influential Relational Model of Authority states that relational concerns play a major role in the individual’s sensitivity to procedural justice. People care about procedural justice because it communicates that their interaction partner values them, and this information validates their status, identity, self-esteem, and self-respect.

Research conducted by Esther Kluwer and her colleagues indicates that the relationship between procedural justice in the context of a relationship conflict and several outcome variables (affective feelings and relationship satisfaction) is stronger for women than for men, suggesting that women react more strongly toward procedural (in)justice than men. This gender difference disappeared under conditions of strong relationship orientation.

A strong relationship orientation made men more vulnerable to how they were treated by their partner during a relationship conflict. The findings suggest that procedural justice operates at a dispositional level for women, who are generally more relationship oriented, whereas it operates at a relationship-specific level for men. Men are affected by procedural justice only when they are highly committed to their relationship, when they strongly identify with their partner, or when their relationship is experientially made salient.

person—the transition from not being in love to being in love. Falling in love appears to be a universal phenomenon, appearing in every culture for which data are available, in every historical era, and in every age group, from 4- to 100-year-olds and beyond. Analogues to falling in love are found in a wide variety of higher animal species and may well have played a critical role in human evolution. Falling in love is often an intense experience, a source of some of the greatest joys, including connectedness, ecstasy, and fulfillment, and some of the greatest problems, including depression, rage, stalking, suicide, and homicide. It is also a common phenomenon: It happens at least once to most U.S. residents at some point in their lives, with only somewhat varying rates across cultures. This entry reviews the literature on the falling in love process, including distinguishing it from onset of sexual desire, discussing predictors of falling in love, and identifying the consequences of the experience of falling in love.

History of the Study of Falling in Love

Falling in love has been the subject of both artistic and scholarly attention from the earliest times. Some classical contributions in Western culture are Plato's *Symposium*, Stendhal's book-length 18th century essay *de L'Amour*, and Sigmund Freud's extensive discussions of the topic. In the 19th and early 20th centuries, cultural anthropologists and clinical writers outside the Freudian tradition became interested in the topic; researchers in the 1960s and 1970s mainly focused on initial romantic attraction between strangers. The 1980s set the stage for much current thinking on romantic love, most prominently including the extension of Attachment Theory to adult love, descriptive work on intense passionate love, the identification of lay understandings of love, and the development and application of relevant theoretical models. Researchers in the early 1990s added work on unreciprocated love and love ideals. The major developments in the late 1990s and early 21st century include an upsurge of interest in romantic love in adolescence and old age, ethnic and cultural differences, love as an emotion, and—most prominently—biological approaches, including work on oxytocin and vasopressin in

FALLING IN LOVE

Falling in love is the onset of a strong desire for a close, romantic relationship with a particular

monogamous prairie voles, the related work it has inspired in humans, and brain imaging and other neuroscience methods.

What Is Falling in Love?

As noted, falling in love is the transition from not being in love to being in love. The metaphor of “falling” suggests a rapid transition, but many individuals report a gradual transition, sometimes over years, as from an acquaintanceship to an intense passion. Nevertheless, regardless of how long it takes, falling in love for most people clearly refers to a transition from something not at all intense to something quite intense, involving a major redirection of one’s attention and energy, and more than just a passing or ephemeral attraction or valuing of an individual.

The key definitional issue has been about what is being fallen into: “What is love?” Extensive research by Beverly Fehr and others has shown that people understand love by its resemblance to a prototype, a standard model, or idea (as one would recognize a bird by its resemblance to a robin). The prototypical features of love encompass, in order of centrality, intimacy, commitment, and passion. Scientists such as Art Aron, by contrast, have defined love in a more formal way, for example, as “the constellation of behaviors, cognitions, and emotions associated with a desire to enter or maintain a close relationship with a specific other person.” Researchers have found romantic love to be associated with dependence, caring, and exclusiveness, as distinguished from mere liking, which emphasizes similarity, respect, and positive evaluation. Elaine Hatfield and Ellen Berscheid also distinguished passionate romantic love (“intense longing for union with another”) from companionate love (“affection . . . for those with whom our lives are deeply entwined”). Some items on the standard research measure of passionate love are “I would rather be with ___ than with anyone else” and “I melt when looking deeply into ___’s eyes.” A similar distinction is between those whom one “loves” and the subset of these with whom one is “in love.”

Other research approaches have focused on typologies. One, based on the work of John Alan Lee and Clyde and Susan Hendrick, identifies six “love styles:” *eros* (romantic, passionate love),

ludus (game-playing love), *storge* (friendship love), *pragma* (logical, “shopping-list” love), *mania* (possessive, dependent love), and *agape* (selfless love). Another influential approach is the Triangular Theory, developed by Robert Sternberg, which conceptualizes love in terms of intimacy, commitment/decision, and passion, the various combinations of which define diverse types of romantic love.

Falling in Love Versus the Onset of Sexual Desire

Sexual desire is clearly linked with passionate love. For example, the features that identify the lay understanding of love include “sexual passion” and “sex appeal.” Similarly, the standard measure of passionate love described earlier includes items emphasizing physical response to the partner. Nevertheless, romantic love and sexual desire have been shown to be associated with different nonverbal cues and behavioral responses. For example, head nodding and smiling are significant predictors of love but not necessarily of sexual desire. Another relevant finding is that 5-year-old children, who presumably do not have the same kind of sexual response as do adolescents, report levels of passionate love as high as 14 to 18 year olds. Finally, brain imaging studies of romantic love have consistently found patterns of brain activity that only minimally overlap with activation patterns found in studies of sexual arousal.

Variations in Falling in Love

Personality

Those who fall in love most often and most intensely are people high on a dimension of “anxious-attachment,” those who, presumably as a result of inconsistent love from their primary caregiver as infants, as adults are hungry for love, tending to seek it more avidly and to be more engaged in the concern about the partner’s response. Other research has reported a similar pattern for those with low self-esteem.

Gender

On average, and across the cultures studied, men appear to be more variable (either having

been many times in love or none at all) and are more romantic and passionate than women are, but women are more likely to be in love at any given time. However, nearly all observed gender differences are only slight average trends, with substantial overlaps between the genders. Many studies find no gender differences.

Cultural Context

Cross-cultural comparisons suggest that people fall in love everywhere, that there is a universal, core element of passionate love. However, how it is enacted may depend heavily on the cultural context. In particular, the greatest variation seems to be in just what precursors lead to falling in love and different styles of expressing and experiencing love and in its incidence across the life cycle. Much of the cultural variation may be due to people in “collectivistic” cultures (e.g., many Asian societies), compared with those in more “individualist” cultures (e.g., North American societies), being less motivated to separate from the family and community context to become intimate with each other.

Whether or Not the Love Is Reciprocated

Autobiographical accounts of being rejected and of being the undesired object of someone's attraction have reported that rejection can lead to strong organization as well as strong disorganization of thoughts, behaviors, and emotions. Both the rejectors and rejectees largely express passive behaviors, both are unhappy with the situation, and both usually end up disappointed. The intensity of a person's feelings of unrequited love can be predicted by how much the individual wants the relationship, how much he or she likes the state of being in love (whether reciprocated or not), and whether the rejectee initially believed his or her love would be reciprocated.

Predictors of Falling in Love

Numerous experiments have identified factors that lead to liking in general and to initial romantic attraction. These factors include discovering that the other person likes one's self; attraction to the other's characteristics, including kindness,

intelligence, humor, good looks, and social status; similarities with one's self, especially in attitudes and background characteristics; proximity and exposure to the other; confirmation and encouragement from one's peers and family that this is a suitable partner; and meeting under conditions of shared humor. With romantic attraction, versus mere general liking, there is a greater importance of physical appearance and that the being liked by the other is specific to oneself (as opposed to the other person liking everyone). In addition, a predictor specific to romantic attraction is being physiologically stirred up at the time of meeting a potential partner. For example, one study found that men who met an attractive woman when on a scary suspension bridge were more romantically attracted to her than were men who met the same woman on a safe bridge; another study found that individuals felt greater romantic attraction to an individual whom they met just after running in place for a few minutes! Finally, systematic analyses of people's retrospective accounts of falling in love find that the most common scenario is discovering that a reasonably appropriate and desirable person is attracted to you.

Effects of Falling in Love

Those experiencing intense passionate love report a focused attention on the beloved, heightened energy, sleeplessness, loss of appetite, euphoria and mood swings, bodily reactions such as a pounding heart, emotional dependence on and obsessive thinking about the beloved, emotional and physical possessiveness, craving for emotional union with the beloved, and intense motivation to win this particular partner.

Is this a good or a bad thing? On the one hand, in the week after falling in love, people experience an increase in self-esteem and an expanded, more diverse sense of one's self. Further, falling in love quickly and intensely, including idealizing the partner, is associated even years later with less divorce and more positive relationships. On the other hand, falling in love may be much less positive, as when it is not reciprocated or when one is already in a relationship with someone else. Also, falling in love can be highly disruptive of one's friendship network. Whether falling in love is seen as a good

or bad thing also seems to differ by cultures. For example, Chinese, more than U.S. residents, associate it with negative features such as sadness, heartbreak, and darkness.

The Biology of Falling in Love

In her 1998 review of the animal literature, anthropologist Helen Fisher concluded that birds and mammals evolved several distinct brain systems for courtship, mating, and parenting, including (a) the sex drive, characterized by a craving for sexual gratification; (b) attraction, characterized by focused attention on a preferred mating partner; and (c) attachment, characterized by the maintenance of proximity, affiliative gestures and expressions of calm when in social contact with a mating partner, and separation anxiety when apart. Each neural system is associated with a different constellation of brain circuits, different behavior patterns, and different emotional and motivational states. With regard to human love, one can equate “attraction” with falling in love. Indeed, recent human studies using brain imaging and biological markers confirm this view.

How Does Falling in Love Work? Major Theoretical Approaches

Love as Attachment

Attachment Theory, originally developed by John Bowlby in relation to infants and extended to adults most prominently by Philip Shaver, has been among the influential approaches to understanding romantic love. The theory emphasizes that early experience with caregivers strongly shapes individual differences in adult love experiences. Thus, for example, those who have had inconsistent caregiving (e.g., those high on the anxious attachment dimension) are much more likely as adults to experience intense passionate love. They are also more likely to experience intense unrequited love given their propensity to easily fall in love but not to trust that the other returns the love, even if the other does return the love. In contrast, those who experienced a consistent lack of security as an infant are said to be high on the avoidant dimension of attachment. As adults, they are

especially unlikely to fall in love, given their tendency to reject passionate love as real and to avoid closeness of any kind.

Love as a Story

Sternberg suggested that loving relationships can be described accurately by the people involved through narrative autobiographies, often suggesting culturally prototypical “stories.” For example, the story of a couple locked in constant struggle is common, as is the story of couples growing to love each other over time. Each type of story has a characteristic mode of thought and behavior that often corresponds to other views of love (e.g., someone with a game-based love story will behave in ways consistent with the ludus love style). Having a particular love story can also affect one’s expectations of what a romantic relationship should be like. People tend to seek romantic partners with similar love stories and complementary roles within these stories. Finally, these stories are inextricably linked with the rest of one’s life: Particular stories can influence behavior in a relationship, and stories can be shaped and modified by one’s experiences.

Evolutionary Approaches

Because courtship and mate choice are central aspects of reproduction in avian and mammalian species, it seems plausible that the experiences, behaviors, and neural underpinnings of falling in love might be strongly shaped by evolution. Thus, as noted earlier, Fisher proposed that the brain system for romantic attraction evolved to motivate individuals to select among potential mating partners, prefer particular conspecifics, and focus their courtship attention on these favored individuals, thereby conserving precious courtship and mating time and energy. Other evolutionary-oriented theorists have proposed that many human traits, including language and even some artistic talents, evolved as display devices to trigger attraction. Another important line of evolutionary thinking emphasizes gender differences in what features are desirable in a mate. For example, across cultures, men more than women consistently say they care more about a potential partner’s physical appearance and women more than men care about a

potential partner's social status. Finally, some approaches to the evolutionary basis of romantic love have argued that the mating system exploits an evolved bonding module between infants and parents.

Self-Expansion Model

Another approach to understanding falling in love is Arthur and Elaine Aron's Self-Expansion Model. This model posits (a) that a primary human motivation to expand one's self in terms of potential to attain desired goals and (b) that a main way people seek to expand the self is in terms of "including others in the self" through close relationships so that the other's resources, perspectives, and identities are treated to some extent as one's own. Both principles have received considerable research support. In terms of romantic love, the researchers argue that the exhilaration and intense, focused attention of passionate love arises from the rapid rate of including the other in the self often associated with forming a new romantic relationship. Falling in love, according to this model, arises when one perceives the opportunity for substantial self-expansion by including a particular other person in the self.

Conclusions

Falling in love is much less a mystery than it once was. Scientists are no longer just watching the storms and heat waves with at best only a poetic sense of what is going on. We know what people mean fairly precisely by "falling in love." We know that it is not just sexual desire. We know many of the systematic similarities and differences across personality, gender, culture, and whether the love is reciprocated. We know a fair amount about falling in love's effects on the individual experiencing it and on how its intensity affects relationships that develop from it. We know a great deal about the variables that predict falling in love. We have a growing basis for understanding its biological correlates and cross-species similarities. And several theoretical approaches offer substantial insights into underlying mechanisms.

Yet, mystery remains. Most of what we know, as noted throughout this entry, is extrapolation

from work on initial attraction or on romantic love, the states on either side of falling in love, each of which has been much more thoroughly studied. Nevertheless, one can look forward to continued important work using existing approaches, as well as to exciting findings from entirely new approaches or new adaptations of successful paradigms from other research domains. Given the sophistication and innovation that have characterized research in this area to date, it seems likely that it will not be long before falling in love is as well understood as other relationship phenomena. Indeed, one can look forward in the not too distant future to both being and falling in love becoming as well understood and predictable as the next storm or heat wave.

FAMILIARITY PRINCIPLE OF ATTRACTION

The *familiarity principle of attraction* refers to the idea that objects and people seen repeatedly are subsequently rated more positively than are those seen less frequently. This principle stems from research on the *mere exposure effect*, which predicts that repeated exposure to neutrally valenced objects increases *attitudes*, or evaluations, of those objects. Early studies on the mere exposure effect varied the exposure frequency of nonsense syllables and Chinese characters (to non-Chinese fluent samples) and showed that those seen more frequently were rated more favorably. These effects seem to generalize even to non-humans; rats have been shown to prefer music that they were raised with to novel music.

Subsequent research has investigated the effect of increased exposure on social stimuli. For example, hearing a rumor repeatedly can lead one to believe that the rumor is true. When it comes to interacting with people who have been seen frequently, there are a wide range of effects. For example, people tend to agree with persuasive arguments from individuals they are familiar with, compared with that same argument from those they were not previously exposed to. Likewise, people tend to comply with the requests of those they are familiar with. At the foundation of these effects is the fact that we like those that we have seen repeatedly. Laboratory studies have shown that individuals prefer to interact with those with whom they have had more previous exposure. In addition, faces presented more frequently are rated as more attractive.

These findings generalize beyond the laboratory as well. In a clever study, researchers planted four

female confederates in a college class (i.e., they posed as students). The confederates were pre-tested to be of similar physical attractiveness, and their class attendance was varied during the semester. At the end of the term, there was a strong association between students' ratings of the confederates and their class attendance (i.e., familiarity); the confederate who came to class most frequently was rated as the most attractive and likeable, and the one who never came to class was rated lowest on these dimensions.

The effect of familiarity can even be seen in individuals' preferences for pictures of themselves compared with their friends' preferences. Because we typically see ourselves "backward" (i.e., in the mirror), we tend to prefer our own images if reversed. However, our friends typically see us the "right way," and they will prefer our non-reversed picture. Furthermore, when rating the attractiveness of opposite-sex others, participants prefer faces of others that look similar to themselves. Using computerized image-morphing, participants were shown a range of faces, and unbeknownst to them, some included their own face transformed into an opposite-sex target; these were the faces that received the highest attractiveness ratings.

In addition to the implications for liking in interpersonal relationships and attraction, the familiarity principle has been applied extensively in consumer and political contexts. According to this perspective, one rationale for the frequency and effectiveness of advertising is that viewers should prefer products and political candidates that they have seen more often.

Many potential mechanisms underlying the mere exposure effect have been investigated. One particular process that has received support is that familiarity involves *classical conditioning* in situations absent of aversive events. It is possible that the lack of aversive stimuli elicits a positive response, which through subsequent trials (i.e., exposure) becomes paired with the person or target repeatedly presented, yielding a preference for those objects or people that are familiar. In addition, the principle of familiarity makes sense from an *evolutionary perspective*; those objects that are seen often are viewed as safe and pleasant, whereas unfamiliar things are unknown and may promote uncertainty. A preference for familiar

objects would have led individuals to gravitate toward safe and predictable situations and away from the unfamiliar, thus facilitating survival and reproduction. Therefore, according to this perspective, selective pressures would have reinforced the preference for familiar stimuli within ancestral populations.

Familiarity effects have been found to be stronger when people are unaware that they have seen the stimulus more often and when stimuli are presented for short durations. For example, the mere exposure effect can occur when stimuli are presented *subliminally*. The familiarity principle, however, does not mean that increased exposure to people or objects that are previously disliked will lead individuals to like them more. Though liking for neutral objects or those with a preexisting positive evaluation may be facilitated with increased exposure, evidence indicates that increased exposure to negatively evaluated objects causes a further decrease in liking of those objects.

Closely related to the familiarity principle are the effects of *proximity* on attraction, which predicts that people will be attracted to those who are physically nearby, given that those in close proximity are also likely to be seen more often and offer opportunities for interaction. Thus, the familiarity principle is one explanation for why proximity is associated with attraction.

FAMILIES, COPING WITH CANCER

The diagnosis and treatment of cancer has immense emotional and practical repercussions for the entire family as well as for the patient. Although the medical community has long treated cancer as a “family disease,” the psychological implications of cancer on families have only begun to receive empirical attention during the past two decades. This entry focuses on the psychological ramifications of the diagnosis of cancer on the adult and his or her spouse, children, and other family members, as well as the role of family support in psychological adaptation to cancer.

Impact of Cancer on the Spouse and the Marital Relationship

Most studies suggest that between 20 percent and 30 percent of spouses report clinically relevant levels of psychological distress, although higher rates of distress (50 percent) have been reported among spouses of individuals with advanced stage disease. Numerous studies have compared rates of distress of patients and their partners, but a recent meta-analysis suggests that the higher rates of partner distress reported in previous studies might be associated with gender: Women report more distress than men regardless of whether they are the person with cancer or the spouse. Many couples are drawn closer together by the cancer experience, but a subset of couples, particularly those with preexisting marital dissatisfaction, report increased marital difficulties after cancer. Although some early studies suggested that divorce or marital separation were more likely after cancer, current research does not consistently support this contention.

Impact of Parental Cancer on Children

Current research indicates that most children who have a parent with early-stage cancer do not experience clinically relevant psychosocial problems. However, evidence suggests that children experience greater internalizing problems, such as depressive or anxious symptoms. Adolescents report more anxious, depressive, and aggressive

symptoms than prepubescent children do. Gender of the child, as well as gender of the affected parent, may influence how the child copes with parental cancer. Adolescent daughters, particularly daughters of women with cancer, report greater internalizing difficulties relative to sons, or to adolescents of either gender whose fathers have cancer. Other evidence suggests that families coping with cancer may experience positive outcomes, such as less family conflict, greater family expressiveness and cohesiveness, and better social competence among children. Though most data indicate that illness-related variables are not related to children's functioning, at least one study found that depressive or anxious symptoms decreased for both children and adolescents as the time since diagnosis increased. Most studies have focused exclusively on children experiencing maternal cancer; paternal cancer may not have the same effect.

Impact of Cancer on Patients' Adult Siblings and Parents

Few studies have examined the impact of cancer on adult siblings and parents of individuals with cancer. Sisters of breast cancer patients who are at high familial breast cancer risk (i.e., from hereditary breast-ovarian cancer families) report that they do not experience increased psychological distress. However, other studies have reported that female first-degree relatives (i.e., parents, siblings, and children) of breast cancer patients, who are at increased (but not necessarily familial) risk report high distress, suggesting that community samples may report higher distress than relatives of women recruited from cancer risk registries. Studies assessing distress in first-degree relatives providing care to cancer patients indicate that levels of distress may be influenced by the type of cancer the patient has.

A large body of literature examines how pediatric cancer affects families, a topic too extensive to include in this entry; however, few studies have looked at the impact on parents of adult children diagnosed with cancer. Most studies have examined parents whose adult children died from cancer. These studies indicate that parents may feel uncertain of their role in their

adult child's healthcare and experience conflicting desires to care for their child as well as allow him or her to maintain autonomy. One study examined parents' distress approximately 2 years after the death of their adult child from cancer and found that parents did not report higher than normal levels of distress. Psychological issues of adult family members of individuals with cancer would benefit from greater empirical attention.

Family Support and Cancer

Social support is one of the most-studied contributory factors to the psychological adaptation to cancer. Social support is typically defined as the perception that emotional, practical, self-esteem bolstering, or informational help would be available from others if it were needed or the perception of the receipt of these same behaviors from others during the cancer experience. Other studies have evaluated perceived satisfaction with support provided by others. Most studies have evaluated global perceptions of support from the patient's network of family and friends with relatively few studies separately examining the role of support provided by family. In these studies, family support generally correlates positively with mental and physical health. Among family members, spouses are the most studied source of social support. Both perceived and received spousal support predict higher levels of psychological adaptation, with several studies suggesting that supportive responses from spouses predict adaptive coping responses such as greater use of problem-solving coping. Not all responses from family are viewed as supportive by cancer patients. For example, avoidance of talking about the cancer by changing the topic and responses that are perceived as minimizing the patient's concerns are considered unsupportive, and these responses, both from spouses and other family members, have been associated with greater psychological distress as well as with less adaptive coping strategies by the individual with cancer, including avoidance. The literature to date suggests that not avoiding talking about the cancer, asking the patient and his or her family members directly what he or she wants in terms of support, and

attempting to provide esteem-bolstering support are all beneficial.

Family-Focused Interventions

Although support from family is a key resource for patients coping with cancer and bolstering support is likely to be beneficial effects for both patients and the family members who care for them, few psychological interventions incorporate family members. Family-focused grief therapy, which includes patients with advanced cancers at the end of life and their family members, has been shown to facilitate post-death adaptation of family members. Couple-focused group and individual couples' interventions have also shown promise in reducing distress for patients and their partners. Finally, recent studies targeting distress among family caregivers of patients with advanced disease have shown promise. Psychological interventions may benefit from including family members.

FAMILIES, DEFINITIONS AND TYPOLOGIES

Family is the primal relational experience for most people. Most people assume that they know what a family is. Yet, the basic definition of this universal phenomenon has recently become intensely controversial. Recently, California's Supreme Court followed Massachusetts in ruling that gays and lesbians can marry and raise children—in essence establishing a legal family—just as heterosexuals do, although this ruling was overturned by public referendum. Whether referendums to ban gay marriages are passed, traditional definitions of family are changing. The rise of gay rights is not the only social change to challenge traditional notions of family. With the divorce rate long higher than 50 percent, single-parent and blended families have become as commonplace as the traditional nuclear family with a father, mother, and biological children. Likewise, the rise of long-term cohabitation has created a social unit, sometimes called a *common-law marriage*, that has also challenged traditional conceptions of family. Laws protecting children have also led to increasing numbers of children being removed from their biological parents and adopted or placed in foster care. Likewise, there are cross-cultural variations in what constitutes a family and what a family looks like. Polygamy is accepted in some cultures or subcultures but not in others. Different cultures have different traditions for where to draw the boundaries of the extended family. All of these variations have political and legal implications.

This entry presents three approaches to defining what constitutes a family: structural, functional, and process. It also describes several of the most popular and useful family typologies.

Definitions

Dictionaries usually define terms reflecting common usage. Scholars define terms to facilitate research and communication, not necessarily to advance a political agenda. Nevertheless, because a definition of a family typically includes certain social groupings and excludes others, most definitions will have political implications. Some people

have attempted to skirt the issue by simply saying that a group is a family when its members say that it is. Whereas this approach probably works well for most practical situations, it may not prove useful for systematic research, analysis, or understanding. Scholars have usually defined *family* in terms of structures, functions, or processes.

Structural Approach

Structural approaches to defining what a family is may be the most challenged by societal changes and cultural variations. The structural approach usually distinguishes between the *family of procreation* (often called the *nuclear family*) and the *family of origin* (also called the *extended family*). The family of procreation is the “immediate family” in a household responsible for the raising of children, usually parents and their children. The extended family includes less immediate relationships including in-laws, grandparents, aunts, uncles, cousins, and so on. The bases of the family’s relationships are viewed as biological (blood) and legal (e.g., marriage or adoption). The challenges to legal distinctions have been noted; however, with the rise of in vitro fertilization and surrogate parenting, even the biological basis for family membership is potentially controversial.

Typically, structural definitions require at least one adult or guardian and at least one child (though the child can be an adult). A marital relationship is typically considered a subsystem or part of the family system, but not a family by itself. A typical structural definition would describe a family as *an intergenerational social network of relationships based upon biological (hereditary) and legal (e.g., marriage, civil union, or adoption) kinships*.

Functional Approach

A functional definition defines a family in terms of the function(s) that it accomplishes. The primary function that most people identify with family is the raising of children—both their nurturing and their socialization. However, families also provide other functions (e.g., social support), but these often do not distinguish them from other social groups or networks. As families progress through their life cycle, the function of care and support often shifts such that children are

responsible for the support and care of their parents. In a purely functional definition, a group is a family if it accomplishes the functions of a family, regardless of its structure. Whereas some definitions focus on structure and others on function, these are not mutually exclusive. Structures often evolve to support functions. A typical definition that combines the structural and functional approaches holds that a family is *an intergenerational social network of relationships based upon biological (hereditary) and legal (e.g., marriage, civil union, or adoption) kinships whose primary functions are the socializing, supporting, and nurturing of children and other family members*.

Process Approach

It has become increasingly popular to define families in terms of the communication and social-psychological processes that characterize them. Processes, like structures, cannot be separated from the functions that they accomplish. Processes are the means by which functions are accomplished. These definitions focus upon *how* groups function as families.

Families are highly interdependent. The behavior of one member affects all other members, and all members of the family share a common fate. The needs of an infant may place an added burden on a working parent, may require an added time commitment from a nurturing parent, and may take away from time and resources available to another child. When mom loses her job, dad may have to work more hours, and daughter may not get her own car or may not have enough to eat. When children quarrel, parents may need to step in to mediate, and when parents quarrel, children are emotionally affected. It is both popular and useful to consider a family as a *system* (i.e., an interdependent group that acts as a unit because of the relationships between its members and subgroups). Whereas family systems may vary in the degree to which they orient inward or interact with the outside world, for a family to act as a system, some degree of coordinated interdependence and identity is necessary.

Families are intimate interacting systems. Though families and individuals within families certainly vary in the extent to which they guard their privacy or are open and confiding (see the following discussion of

family types), a degree of intimacy is unavoidable in an intact family. By virtue of the degree of interdependence, the amount of time that they spend together, and the basic requirements of family life, private and personal information is more available to family members than to most other people. Family members know what other members look like before they comb their hair, and they know how other members act behind closed doors.

Probably more than any other type of group, *families create their own social realities*. Children come to know who they are by how others treat them, and the first and most important source of such information is the family (parents, grandparents, and siblings). A child's identity is initialized by the family. Children are socialized into a culture, and they are indoctrinated into a worldview that the parents and other family members negotiate and cocreate. If children are loved and protected in the family, they are likely to see the world in a different way than if they are abused, neglected, or told that others are out to hurt them. Research on Attachment Theory shows that these views of self and others formed within the family system predict emotional coping, cognitive development, and the nature of future relationships.

Families require commitment. Though members may be born into a family, if they lose their loyalty or ties to the family, the family ceases to function as an ongoing interdependent system. Members can drift away from each other and remain members in name only. Such a group might remain a family under the structural definition but would not be a family under a process definition. It is, of course, more difficult to "divorce" one's family than to separate from most other social groups because of legal and social pressures. This may be what is responsible for many behaviors within families (e.g., rudeness and conflict) that might break apart groups with less commitment.

Families maintain a degree of continuity of relationships over time. This does not mean that they don't develop and change—they do—but the relationships extend over years and generations. Many groups create a group identity, but *a family creates a "sense of home."* This is a feeling of belonging and a sense of place that extends beyond the present to the past and future.

As noted in the following typological discussion, there is a lot of variation both within and

across cultures in the extent of interdependence and identification with the family. For example, in collectivist cultures, the interdependence and sense of identity with the family is likely to be much higher than within individualistic cultures. Nevertheless, a degree of interdependence, commitment, and identity is necessary for a group to function like a family.

According to a process definition, a family is *an interdependent and intimate interacting system, which creates its own social reality, its own conception of home, and maintains itself through a continuity of commitment over time*. This begs several questions. In addition to what one normally thinks of as a family, can a social gang (the Mafia or the Crips) be a family under this definition? Yes, and it has been argued that the need for a sense of "family" is a primary reason why people often join such groups. Are a biological mother, father, and son or daughter who by choice no longer have contact or interaction still a family under this definition? No. Nevertheless, most intact groups that would be considered families under the structural definition would also be defined as families under the process definition. Likewise, the prototypical instance of the process definition family would be the prototypical structural family. Definitions are evaluated based upon their utility. The process definition invites focus on the central communication and social-psychological processes that create the family experience.

Family Typologies

It is not controversial to observe that not all families are alike. The question is, on what systematic basis does one differentiate between families? To say no two families are alike, though true at some level, is of little help in improving understanding. Whereas there are many ways to differentiate between different types of families, a *typology* makes those distinctions systematically based on a set of fundamental principles. As the previous discussion would suggest, these distinctions can be based on variations in structure, function, or process.

Typologies based on structure may differentiate families according to who is considered part of the family system and the biological or legal basis for such inclusion. Variations from the prototypical

nuclear family (two married parents with children) include single-parent families, foster or adoptive families, blended families, civil unions with children, grandparents raising grandchildren, and so on.

Typologies Based on Processes

Several typologies distinguish between families based on distinctions in functions or processes. David Reiss proposed a typology based on the issues or functions that the family is most sensitive to. He suggests that families may be consensus sensitive, interpersonal distance sensitive, or environment sensitive. This typology holds that environment-sensitive families are more likely to produce children who are mentally healthy.

David Kantor and William Lehr proposed an early typology of families based on three targets or goals (affect, power, and meaning) and three access dimensions (space, time, and energy). Family members seek to obtain affect or power or make sense of things using space, time, and energy. Variations in these goals and processes constitute the ways in which families handle the fundamental issue of autonomy and connection. Kantor and Lehr proposed three types of families.

Open families maintain flexible boundaries such that family members freely interact with their environment and the world outside the family and what is learned feeds back to influence the family system. Rules and understandings are also subject to negotiation and change. For example, the parents of a daughter in an open family might always make sure that she gets to spend time with her friends and do things outside the family. However, she must let her parents know beforehand where she is and what she's doing. She might even go away with her friend's family for vacation instead of with her own family.

Closed families maintain more fixed boundaries by interacting less with and being influenced less by the outside world and spend their time and energies on the family. This produces a higher degree of predictability in how they interact and function. For example, a son in a closed family might spend every weekend with his family. On those few occasions he does spend time with his friends, his parents monitor his activities carefully. This family might hold to the motto "what goes on in the family stays in the family."

Random families by contrast tend to be highly unpredictable with members at times maintaining a high degree of separation or autonomy from the family. For example, a child in a random family might never know who will be at home when she comes home from school or where her parents might be. Her family may never all sit down to dinner together. Whereas the open family is flexible, the random family is chaotic and disjointed.

David Olson and his associates use two separate dimensions to distinguish between families: cohesion and flexibility. According to this typology, families that are too extreme on either of these two dimensions are likely to be dysfunctional, whereas those that are more moderate are more functional. If a family is too cohesive (enmeshed) or lacks any cohesion (disengaged), it is dysfunctional, whereas families that are moderate (i.e., connected or separated) are healthier. An enmeshed family may not allow any autonomy for its members or exhibit "codependency" (the inability of members to separate their own feelings from those of others). Disengaged families would be families in name only, but fail to function as a unit. Likewise, families that are either rigid or chaotic (not flexible enough or too flexible) are unhealthy, but moderately flexible or structured families are likely to be healthier. A rigid family adheres so strictly to proscribed rules or structures that family members cannot adapt to changing or novel situations. A chaotic family has so little structure that there is no predictability or coordination of the family unit. The combinations of four levels of these two dimensions produce 16 family types. Whereas the underlying dimensions of the Olson typology are similar to the Kantor and Lehr typology, cohesion and flexibility are viewed as more distinct in the Olson system and Olson makes finer distinctions and, therefore, proposes a more elaborate typology. This typology may have its greatest benefit for family therapists, but may not describe families in ways that the family members themselves would identify with.

Jack McLeod and Steven Chaffee proposed a typology of families based on communication patterns, which was further developed by Mary Anne Fitzpatrick. Families are typed based on their members' self-reports on two aspects of family communication: conversation orientation and conformity orientation. These two dimensions

form the basis by which families create their own social realities.

Families that focus more on conversation and concepts than on conformity in forging their reality are called *pluralistic families*. Their family communication is unconstrained and open regarding all family members. For example, a married couple may be strong Democrats, but when their son begins expressing conservative ideas and supporting Republican candidates, the parents engage him in debate without demanding that he change his views.

Protective families are oriented more toward conformity than toward open conversation and, therefore, their communication is based on conformity to parental authority and limited concern for conceptual issues. Unlike the prior example, such a family would not encourage the expression of views, political or otherwise, conflicting with the parents' expressed worldview.

Families that attempt to use both open conversation focused on concepts *and* adherence to parental authority are termed *consensual families*. Their communication displays the tension that comes from the tendency to conform while attempting to openly discuss new ideas and issues. In the example of differences over political orientation, the family would be in tension until all members were able to negotiate a common family viewpoint.

Finally, when families are focused on neither conformity nor open conversation, they display the uninvolved or disengaged relationships of a *laissez-faire family*. For example, in such a family, members might not know or care about the political positions of other members.

There are clear similarities between the Kantor and Lehr, the Olson, and the McLeod and Chaffee typologies. For example, the descriptions of the random, disengaged, and laissez-faire families are somewhat similar, though not necessarily identical. They come close to not being families under the process definition. For these types to qualify as a family under the process definition, some limited degree of cohesion and coordination are necessary. All of these process typologies consider how families create their own reality, negotiate autonomy and connection, and display predictability or flexibility. However, McLeod and Chaffee's typology does not view any family type as inherently

functional or dysfunctional. Rather, each type has its own strengths and weaknesses. There can be functional and dysfunctional families in each of the four types.

FAMILIES, DEMOGRAPHIC TRENDS

This entry reviews various demographic trends and, in so doing, illustrates the fluidity and complexity of families. Before beginning the discussion, it is

worthwhile to review a few terms. *Demography* is a study of characteristics pertaining to the human population, such as fertility, mortality, structure and distribution, geographic mobility, immigration, emigration, and population density. This includes examining changes over time. *Family demography* involves examining factors associated specifically with the family, such as number of families, presence of children, living arrangements, and relationship status. Much of this information can be obtained from U.S. Census data, which contains a collection of demographic information. This enumeration (or headcount) is mandated by the U.S. Constitution. In a U.S. Census *Current Population Report* developed by Jason Fields (2004), family living arrangements were reviewed.

According to Fields's (2004) report, the Census Bureau developed two typologies—*family households* and *family groups*—in an attempt to assess demographic characteristics of families.

- *Family households*: A household is defined as everyone residing in a housing unit. It may consist of one or more people. The householder is the person who rents or owns the unit. There are family households and nonfamily households. Unlike a household, a family household consists of at least two related people; these people can be related by marriage, birth, or adoption. One of these people is the householder. Children may or may not be present in family households. Family households, according to definitions provided by the census, are maintained either by married couples or by a man or a woman with whom other kin are living. Identifying family households entails asking who in the home is related to the householder.
- *Family groups*: Identifying family groups entails counting family units. In this case, the householder may or may not be a member of the family. This means that family groups include all related and unrelated subfamilies. An example of an unrelated subfamily is a married couple who is not related to the householder. An example of a related subfamily is an offspring and that offspring's spouse living in the household of the offspring's parents.

There were about 76 million family households and 79 million family groups in the United States in 2003.

A factor that generally comes to mind when discussing families is the presence of children. About 60 percent of nonmarried-couple family groups and 45 percent of married-couple family groups included an own child under the age of 18 years in 2003. The proportion of large family groups with children decreased between 1970 and 2003. For example, the proportion of family groups with four or more children was 17 percent in 1970, 8 percent in 1980, 5 percent in 1990, and 5 percent in 2003. Some children living in the homes were older. In 1960, 52 percent of family households included a male adult child aged 18 to 24. In 2006, that figure was 53.7 percent. In 2006, about 14.3 percent of family households included male children aged 25 to 34 living with their parents and 9 percent included adult female children in that age range. There are many possible reasons that adult children return to their parents' home; they may return in need of support as a result of job loss, poor economy, or divorce.

Relationship Status: Trends Among the Married, Never-Married, and Divorced

Although more than 80 percent of the U.S. population will eventually marry, the proportion of nonfamily households has increased since 1970. One reason for this increase is the rise in the age at first marriage. Age at first marriage was reviewed by Jason Fields, who reported that among men, the median age at first marriage was 23.2 in 1970, 24.7 in 1980, 26.1 in 1990, 26.8 in 2000, and 27.1 in 2003. Among women, the median age at first marriage was 20.8 in 1970, 22.0 in 1980, 23.9 in 1990, 25.1 in 2000, and 25.3 in 2003. Although age at first marriage increased for both men and women, women married at younger ages than men did. The proportion of never-married men and women increased slightly during the aforementioned decades. For example, among men, the proportion never-married was 28.1 percent in 1970 but 32.1 percent in 2003. Among women, the proportion never-married was 22.1 percent in 1970 and 25.4 percent in 2003.

A careful examination of specific age groups reveal that between 1970 and 2003, the proportion of never-married women 20 to 24 years old increased more than twofold (that is, 36 percent to

75 percent) and increased more than threefold (6 percent to 23 percent) for women 30 to 34 years old. Significant changes were also observed among men. The proportion of 20- to 24-year-old never-married men increased from 55 percent (1970) to 86 percent (2003); the proportion of 30- to 34-year-old never-married men increased from 9 percent (1970) to 33 percent (2003). Though the proportion of never-married increased, the proportion married decreased. Among men, the proportion married was 65.4 percent in 1970, 61.4 percent in 1980, 58.7 percent 1990, 56.1 percent in 2000, and 55.4 percent in 2003. Similarly, among women, the proportion married was 59.7 percent in 1970, 56.1 percent in 1980, 54.0 percent in 1990, 52.3 percent in 2000, and 51.6 percent in 2003. Socioeconomic status (SES) plays a significant role in marriage trends. The attractiveness, as well as the size, of the marriage pool affects the options of low-income women. Furthermore, an imbalance in the ratio of women to men among the severely economically disadvantaged hinders the ability of women to find spouses. Key trends contribute to this occurrence, such as higher mortality rates among marriageable-aged, low-income men compared with women and the incarceration of a greater proportion of marriageable-aged, low-income men. Although some issues cut across race, other issues tend to be more race-specific. Census data provide information about Whites, Blacks, Asians, American Indians/Alaska Natives, and Native Hawaiian/Other Pacific Islanders.

According to the U.S. Census 2000 brief *Marital Status: 2000*, by Rose Kreider and Tavia Simmons, which was issued in 2003, of all the racial groups, Blacks represented the lowest proportion married; moreover, there was a difference between women and men. Forty-two percent of Black men were married, compared with only 31 percent of Black women. That was the largest difference between men and women among any of the groups. Of all the racial groups, Black men and women also represented the largest proportion who had never been married in the year 2000. Blacks represented the *lowest* proportion married, whereas Asians represented the *highest* proportion married (women, 61 percent; men, 60 percent). Besides racial differences, there are regional differences in marital status as well as differences by state.

For example, states with the highest proportion of people *married* when Census 2000 was taken were Idaho (60 percent) and Utah (59 percent). New York and Massachusetts had the highest proportion of *never-married* people; the proportions were 32 percent and 31 percent, respectively.

Just as marriage trends differed by sex, state, and race/ethnicity, such differences also existed in divorce and separation. In 1970, 3.5 percent of men and 5.7 percent of women were separated or divorced; in 2003, that figure was 10.1 percent for men and 13.3 percent for women, according to Fields's report. When the Census 2000 was taken, Asians represented the lowest proportion separated and divorced (women, 7 percent; men, 4 percent), which means that Asians were less likely to divorce than were other groups. Those representing the highest proportion divorced when Census 2000 was taken were American Indians and Alaskan natives. The state with the lowest proportion of divorced adults was New Jersey (7.5 percent), and the state with the highest proportion divorced was Nevada (14 percent), according to Kreider and Simmons. Instead of married or divorced, some people fell under the category of unmarried-partner households.

Unmarried-Partner Households

The proportion of unmarried-partner households has been increasing. Cohabitation began growing in the 1970s and increased in the 1980s and 1990s. In 1996, 2.9 percent of households were categorized as unmarried-partner households; that proportion increased to 4.2 percent in 2003. More than 4 million households consisted of a householder living with someone of the opposite sex as an unmarried partner in 2003. This may be an underrepresentation for at least two main reasons. First, some people may be hesitant to describe themselves as cohabiting and may alternatively label themselves as friends or roommates. Second, according to Fields, all unmarried couples in a given household are not counted; only householders and their partners are counted. Decades ago, many cohabiting relationships tended to lead to marriage. In the 1970s, about 60 percent of cohabiting relationships resulted in marriage within a time span of about 3 years. That figure

dropped to 33 percent 20 years later. Andrew Cherlin explained that this reflects the trend that fewer trial marriages are leading to actual marriages. Perhaps cohabiting unions are not necessarily trial marital unions.

Relatively New Addition to Decennial Census: Grandparental Caregiving

Earlier, the presence of children was discussed. Not all children are taken care of by their parents. Some are raised—for either brief or extended periods—by their grandparents. Census 2000 marked the first time the decennial census included questions about grandparents serving in the role of caregivers for their grandchildren. This is yet another indication of the complexity of families. Once again reviewing a few terms is worthwhile:

The *Census 2000 Brief* prepared by Tavia Simmons and Jane Lawler Dye indicated that 5.8 million people aged 30 or older living in households in the United States were coresident grandparents—meaning that they were living with grandchildren who were younger than 18 years of age. About 2.4 million of those coresident grandparents *grandparent caregivers*. More than 90 percent of grandparent caregivers were the *householder* or spouse of the householder. Some of those households are referred to as *skipped generation households* because the parents of the grandchildren are not living in the home.

FAMILIES, INTERGENERATIONAL RELATIONSHIPS IN

Intergenerational family relationships are those between family members within a common lineage. Although such relationships tend to be primarily biological, they also arise through adoption, as well as step- and quasi-family arrangements. Although studies of parent–child relations have dominated the literature, a great deal of attention

has also focused on relationships between non-adjacent generations such as those between grandparents and grandchildren. These relationships are noteworthy for their stability and their sheer longevity. With human life expectancy almost doubling in length since the beginning of the 20th century, it is now common for children to reach midlife, and not unusual to reach old age, with at least one parent still alive. Similarly, it has become routine for grandparents to live long enough to see their grandchildren reach young adulthood and beyond. This entry focuses on intergenerational family relationships of older adults with their adult children and grandchildren.

Theoretical Perspectives on Intergenerational Relations

During the past several decades, the study of intergenerational relationships has been principally guided by two conceptual orientations: the solidarity-conflict paradigm and Ambivalence Theory. Building on theoretical and empirical advances in the social psychology of small group cohesion, the solidarity-conflict paradigm codifies the sentiments, behaviors, attitudes, values, and structural arrangements that bind the generations. This scheme is operationalized along seven dimensions: affectual solidarity (emotional cohesion), associational solidarity (social interaction), structural solidarity (opportunities for interaction based on geographic proximity as well as family size and gender composition), functional solidarity (support and assistance), normative solidarity (filial obligation), consensual solidarity (agreement on values and opinions), and functional solidarity (provisions of material, instrumental, and social support of intergenerational family members). Continuing efforts to refine the solidarity model have resulted in the inclusion of intergenerational conflict as a principal dimension. Although conflict was originally conceptualized as the absence of solidarity, it subsequently began to be considered a form of engagement that could exist alongside positive aspects of solidarity.

Most research suggests that the dimensions of solidarity are all-inclusive descriptors of the strength of intergenerational bonds, but other research finds that the dimensions are not additive

and do not form a unitary scale. Alternatives to examining these dimensions additively include clustering approaches that allow the identification of relationship types based on various combinations of the dimensions. Using five dimensions from the solidarity model, the following general types of parent-child relationships were identified in national data: (a) *tight-knit*, characterized by high levels on all dimensions of solidarity; (b) *sociable*, characterized by frequent contact, shared values, and emotional closeness, but little exchange of support; (c) *obligatory*, characterized by frequent contact and exchange of support, but emotionally distant and with few shared values; (d) *intimate but distant*, characterized by emotional closeness and shared values but with infrequent contact and little exchange of assistance; and (e) *detached*, characterized by low levels on all dimensions. Although a plurality of relationships fell into the tight-knit type, the three variegated types—strong on some dimensions and weak on others—formed a majority when taken together. Thus, intergenerational relationships are diverse and complex in form, with most falling somewhere between the polarities of tight-knit and detached.

In recent years, the concept of ambivalence has received much attention as either a competing or complementary perspective to the Solidarity-Conflict Model. *Ambivalence* refers to the coexistence of both positive and negative feelings about those in other generations, often described as having “mixed feelings” toward another. An evolving scholarly debate centers on the question of whether ambivalence is an emergent property of relationships, one that is irreducible to any constituent parts, or whether it can be conceptualized as the intersection of attractive and repulsive tendencies in relationships.

Attempts to bridge the conceptual divide have explicitly incorporated ambivalence into the Solidarity-Conflict Model as the space where opposing dimensions of solidarity and conflict meet to describe contradictory aspects of relationships. Other more critical approaches ask how pressures outside the family such as work responsibilities produce ambivalence by introducing competing demands that tear individuals in two directions with regard to their intergenerational relationships—a phenomenon known as structural ambivalence. Several investigations into sources of

ambivalence in late-life intergenerational relationships have centered on the negotiations surrounding caregiving and the attendant tensions between autonomy and dependency of the older adult and role-reversal of the caregiver.

Life-Span Models of Intergenerational Relationships

Styles of intergenerational relationships in adulthood have their roots in early family experiences. This perspective stresses continuity in intergenerational ties. A key example is the body of research that demonstrates how the strength of parent-child attachment early in the family life cycle is linked to whether adult children provide care to frail aging parents much later in the family life cycle.

Other perspectives consider life-course variations in intergenerational relations based on dynamic conditions in the family. Mapped over the lifetimes of families, norms of filial obligation for older parents, for instance, were found to peak in the middle age of adult children and decline in strength thereafter. Affection for aging parents has been found to be largely stable, but tends to decline with the onset of functional disability that sometimes imposes difficult demands on adult children.

An exchange perspective posits that intergenerational relationships are guided by the principle of reciprocity, predicated on the notion that stable relationships strive toward balance in their exchange of resources. This perspective maintains that the obligation to repay a debt is no less found in intergenerational family relations than it is in market relations—but with a crucial difference. Given that intergenerational relationships are rarely abrogated, they are capable of tolerating relatively long periods of imbalance until the direction of support shifts. Research has shown that parents who provided greater investments of time, money, and emotion in their adolescent and young-adult children tend to receive more social support from those children decades later when old-age vulnerabilities emerge. The metaphor of the “support-bank” has been used to describe this long-term pattern of reciprocity.

Another way parents influence their children is by demonstrating the desired behavior to them. Parents model behaviors they hope their young

offspring will eventually emulate toward them, such as caregiving or sharing time with an older parent. Parents also train or socialize their children to feel responsible for elders in the family. Filial responsibility of adult children has been conceptualized as a form of invested social or moral capital, whereby parents who instilled in their children the duty to help older generations are able to “withdraw” that capital in the form of support.

Social Change and Intergenerational Relationships

Social and demographic changes in the family have been the object of much scrutiny in the study of intergenerational relationships because they influence both kinship structure and function. Declining fertility and increasing divorce rates, combined with the rising labor force participation of women, have raised concerns about the continued viability of intergenerational support for the aged. Evidence shows that older divorced fathers may be particularly at-risk of experiencing support deficits. Demographic shifts can also cause intergenerational realignments. For instance, female labor force participation has reduced the amount of care mothers offer their children but has also increased the likelihood that grandmothers will provide childcare.

Accounting for these social changes has resulted in the need to develop new models of complex family forms. An alternative perspective is that marital disruption and remarriage, and the various family recombinations that result, have increased the kin supply by adding stepkin to biological kin in the support portfolio available to older adults. One example of such a model is the “latent kin matrix” that brings to light how intergenerational relations are negotiated and actively constructed, but also emphasizes greater uncertainty in the durability of these more volitional family ties.

By some accounts, the basis of family life is threatened by reductions in fertility and by the growth of the childless population. Preferences for family size are affected by the perceived cost and value of children. Today, the value of children is tied more to their emotional than to their utilitarian benefits. For example, having children is less needed than in the past to ensure old age support;

public transfer programs and private investments now provide economic security in retirement, and supportive services can be privately purchased or provided by the government. In the developed world, and ever more so in developing nations, fewer parents expect or want their children to be their sole sources of support when they are old.

Demographic change and improvements in population health have also altered multigenerational family roles. Increased longevity and later childbearing have produced families with more surviving generations but with fewer members per family. These elongated family lineages have increased the number of middle-aged individuals who are simultaneously caring for frail older parents and young children or grandchildren. Although there is debate about the prevalence of such families in the population, those in the so-called sandwich generation clearly face difficult challenges if they are still working in the labor force and have fewer siblings with whom to divide the labor in caring for older parents.

Intergenerational Relations in National Context

The availability of internationally comparative data has sparked empirical investigations concerning the role played by national context in micro-family interactions and support. Specifically, relationship intensity, as measured by proximity and frequency of contact, are weaker in nations that are more geographically mobile, possess a less coercive family culture, and have a more liberal public service sector. Thus, older adults in Western Europe tend more to rely on state-provided economic and instrumental support compared with older adults in Southern and Eastern European nations, who tend more to rely on family members for needed support. In part, this pattern reflects fundamental differences in whether intergenerational responsibility for older people is primarily considered a collective responsibility or mainly considered a private concern. In the United States, this tension is reflected in current policy debates about whether Social Security should remain a program that redistributes economic resources across generations or should be privatized as an individual investment vehicle.

Nowhere have intergenerational relations changed more radically than in developing nations of the world. Profound social and economic changes have shifted the center of gravity of the family from being elder-centered to being youth-centered. Extended family structures in many developing countries have traditionally been the basis for economic production, providing older adults with both power and the ability to rely on the wider kinship network. However, recent changes, such as the declining importance of agriculture, rural-to-urban migration of working-age adults, and greater education of youth, have reduced the primacy of the older generation. The ideology of filial piety, found in most East Asian nations, is almost certainly in decline when defined by the degree of intergenerational coresidence. However, other expressions of filial piety remain strong and have even been enhanced by economic growth, such as providing financial support to older parents. The accumulated impact of social change is already altering traditional expectations and forcing the adaptation of social understandings between generations.

Grandparent-Grandchild Relations

Advances in life expectancy increased the availability of grandparents dramatically during the 20th century. Whereas in 1900, only about one-quarter of children were born with all four grandparents alive, today that proportion has risen to slightly more than two-thirds. Grandparenting is a common family role and is currently occupied by about 70 percent of persons in the United States older than age 50. However, declining fertility rates raise the specter of increasing grandchildlessness, as well as increasing competition among grandparents for the attention of fewer grandchildren.

Grandparents vary markedly in the way they enact their roles, ranging from having sole custody of grandchildren to being remote figures in their lives. Generally, grandparents serve as secure attachment figures and confidants to grandchildren, sometimes compensating for various gaps and deficits in the family. For example, grandchildren raised in single-parent and divorced families particularly benefit in their social and emotional development from having close relations with grandparents, as do grandchildren in families with

working parents. A large body of literature focuses on the circumstances of the roughly 10 percent of grandparents who are raising their grandchildren. These studies find that custodial grandparents are self-sacrificing and committed caregivers who heroically substitute for parents under the most dire of family conditions, such as drug and alcohol abuse, incarceration, teenage pregnancy, and extreme poverty.

A wide range of factors influences the nature of grandparent–grandchild relations; these include the grandparent’s and grandchild’s gender, lineage (paternal or maternal), age, family structure, and race/ethnicity. Factors that are out of the control of grandparents and grandchildren influence the way their relationships are maintained. Geographic mobility and divorce of parents, as well as the quality of the grandparent–parent relationship, strongly affect how much access grandparents and grandchildren have to each other. Advances in digital communication technology have mitigated some of the effects of these disruptions, enabling grandparents and grandchildren to maintain independent relationships and stay in touch whether they are across the block or across the world.

FAMILIES, PUBLIC POLICY ISSUES AND

This entry describes current thinking about a significant type of public policy in the United States—family policy. As the diversity of U.S. society and culture has continued to grow, there has been corresponding debate and discussion of the meaning of the concept *family*. For some, the term refers to individuals related by blood (traditional), marriage, or legal adoption. For others, a broader definition that reflects changing demographics and cultural attitudes is more appropriate and useful. In fact, there is no universal definition of family even though everyone grows up in some constellation of people that they consider “family.”

In parallel fashion, in the realm of policy, there is ongoing debate about what “family policy” actually is. From one perspective, it is about policy that explicitly pertains to the business of families (e.g., mutual personal and economic support, procreation, care giving, rearing the next generation). From a broader view, anything and everything that happens in policy (whether in the public or private sector) eventually influences families. Therefore, all policy can be viewed as family policy. A fundamental aspect in discussions of family policy concerns a long-held value in U.S. society that seeks to limit the role of government in family life, that is, to limit the role of public policy in family life. This idea will be expanded in the last section of this entry.

When the two concepts (family and policy) are brought together, that is, when *family* is used as an adjective to modify the term *policy*, the full

range of different worldviews, political agendas, and ideologies are brought to the fore. So, although all policy involves politics to one degree or another, the kinds of debates that characterize family policy are particularly subject to strong ideologically based discussion.

Definitions

Karen Bogenschneider articulated a broad definition of *policy* as a statement, regulation, rule, law, or code adopted for pursuing a course of action. Policies are developed by governments, businesses or other organizations, individuals, families, teachers, coaches, friends, and spouses—to name just a few possibilities. Therefore, *public policy* is but one kind of policy, that which is proposed and produced by any branch of government (executive, legislative, judicial) at any level of government (federal, state, local). Public policy includes every manner of interest to governments and to citizens, for example, defense policy, health policy, environmental policy, monetary policy, and, indeed, family policy. *Family policies* affect families in one or more ways, but family policies may or may not be public policies.

Here are several examples of policies (1–3 are public policies that affect families, whereas 4 and 5 are private sector family policies):

1. Public Law 94-142 (1975), Education of All Handicapped Children Act (now, the Individuals with Disabilities Education Act) provides among other things for a free appropriate public education for all children with disabilities.
2. There will be a 60 percent increase in the minimum wage phased in over a 5-year period.
3. In a state, there is a legal right for same-sex couples to marry, or there is not a legal right to do the same.
4. A family agrees that “we will eat at least 3 dinners a week at home together.”
5. A company will provide, for full-time workers who have been in its employ for more than 10 months, 4 days of paid leave per year to perform home care for family members.

Contextual Issues, Public Policy, and Families

As is the case of family development generally, public policies of importance to families are not islands unto themselves. During the most recent three to four decades, family scholars such as Urie Bronfenbrenner (the ecology of human development), Richard Lerner (developmental contextualism), and Glen Elder Jr. (family life course development) have developed comprehensive approaches to explain the role that extra-familial factors play in family issues more fully. During this same period, there have been significant demographic changes in family structure and functioning in U.S. society, just as there have been in most other countries.

Bronfenbrenner conceptualized these multiple contextual influences on families as a set of interacting systems. The microsystem comprises the family itself—all their relationships, the time family members spend together, the various roles that each performs—and all other systems that contain the family. The church, a community center, a neighborhood, and extended family are all examples of microsystems in which families directly participate. The exosystems that influence families do not contain the family on a regular basis but, rather, indirectly influence families through a process of filtering in which decisions and judgments by others affect the family—for example, a school board meeting, the board room of a public company for which a family member works, a state legislature, a business or company’s health care and other benefits or changes in those, and so on. The macrosystem is yet further removed from direct family context and is the set of societal values, ideologies, laws, and mores that contribute to setting the tone for families in the society.

Neighborhood quality, local and national unemployment levels, quality of available dependent care, policy related to food and drug safety, and workplace policy pertaining to flextime and family leave provide a sampling of issues that both affect and are affected by public and family policy.

On a broader level, it is increasingly observed that national public policies—whether specifically aimed to affect families or, more often, not articulating potential impacts on families—can have strong and enduring impacts on families. For example, consider the effects on families of prison

policy, of whether the nation is at war, of the condition of the national economy, or of trade policy. Although researchers, the general public, politicians, and the media continue to debate what family policy is, whether public and family policy should be less or more expansive, and what the roles and responsibilities of public and private sector policies should be relative to families, U.S. society is increasingly locating families at the center of public policy considerations. Given the high economic and social importance of individual and family development, increased understanding by policymakers and citizens of several essential core policy issues is paramount.

Core Policy Issues

The core policy issues discussed in this section are relevant for all types of public policy, but they are particularly relevant to the family policy realm. In addition, of the four issues discussed, the first, the essential tension between family privacy and government (state) involvement in families, is most influential to U.S. society. This matter is ideological in two senses: first, in relation to the founding of the nation primarily because of inordinate involvement by the monarchy in all aspects of colonial life. Second, although involvement of the community in private family life was acceptable, and even desirable given the challenges to basic survival in the 17th and 18th centuries, colonists drew a sharp differentiation between community involvement and state involvement.

One example of how this tension has reverberated through U.S. history is seen in the history of child abuse legislation. In the mid 1870s, the first case of child abuse was prosecuted by using the laws against cruelty to animals. Thereafter, it took almost 100 years before the individual states in the United States passed child abuse laws to protect children. In effect, these laws gave the government permission to intervene in family life in ways that had previously been unthinkable. These developments bear witness to the deeply held belief that family privacy and government involvement in families are not easily reconciled matters.

A second core policy issue is the issue of direct (explicit) or indirect (implicit) family policy. The focus here is on whether the stated intention of the

policy is to affect families in some way. Examples of explicit public family policies are the Family and Medical Leave Act of 1993 and the Earned Income Tax Credit (first passed in 1975 and expanded periodically since). Examples of implicit policy include the increase in the minimum wage (focused on individual earners in low-paying jobs), which helped increase family income in low-income families, and the changes in U.S. prison sentencing laws in the 1990s, which has affected families in which the father or mother was imprisoned for minor substance-use offenses.

These latter kinds of often unintended outcomes lend support to the broader conceptualizations of family policy, exemplified perhaps most clearly by Sheila Kamerman and Alfred Kahn. Essentially, these approaches assume that any policy (whether aimed at family outcomes or not) has at least the potential to affect families. From this perspective, all policies should be analyzed for their potential impact on families—so-called family impact analysis, which is akin to the environmental impact statement. Others, such as Gilbert Steiner, see this view as much too broad because it includes all (public) policy and does not, therefore, make meaningful distinctions.

A third core policy issue concerns the issue of cost: direct, indirect, short-term, and long-term. The U.S. political system, much like a private sector that often focuses on immediate rather than long-term profit or cost, often does not lend itself easily to long-term strategic thinking. Thus, many considerations of family and public policy focus primarily on short-term direct costs. For example, discussions about educational funding often take this approach even though it is well established that most investments in early childhood education and intervention, investments in childhood immunization programs, and many other prevention policies more than recoup their short-term costs.

Another core policy issue concerns whether the goal of a policy is seen primarily as a “public good” or a “private good.” Consider education: Is education a public good (a benefit to the society at large) or a private good (a benefit to the individual only)? The answer to this question would likely be linked to one’s position on a proposed tax levy to support school funding. Just as the matter of cost is more complex than it first appears, so is the

answer to the question of whether a policy goal is a private good or a public good. In the case of education, for example, the conclusion that it is a private good is supported by the research data showing that economic and other benefits accrue to individuals in direct relation to their years of completed education. However, from a broader perspective, years of education are associated with lower likelihood of violent criminal activity, more years of employment, greater tax payments to the public treasury, and so on—outcomes that support the belief that education is a public good.

Conclusion

Policy, and family policy in particular, is inherently political in nature. When problem definitions and proposed policy solutions consider historical, contextual, and cross-cultural data and experience, they are more likely to be at least partially data based and less likely to be entirely ideologically driven. Finally, the level and quality of explicit family policies vary widely from country to country, as does the degree to which those policies reflect more individual-oriented or more family-oriented approaches to addressing family issues.

FAMILY COMMUNICATION

Family interaction constructs and reflects family relationships and supports members' management of everyday life. In addition to creating families through blood and legal ties, many family members establish and manage their identity and relational ties, in whole or part, through their communication practices. As individuals live longer and experience varied family structures, these issues of meaning and identity become complex.

Change characterizes contemporary family life. No one majority family form exists in the United States. Although U.S. residents continue to marry, and wedded couples account for a slight majority of U.S. households, many of these relationships represent a second or third marriage for at least one partner. Whereas the divorce rate appears to have stabilized, almost half of all marriages still result in divorce; a high percentage of these divorced individuals choose to remarry one or more times, often creating stepfamilies. The percentage of single-parent families continues to rise, as does the number of cohabiting partners. Increasingly, families, including single parents and same-sex partners, are formed in whole or in part through the use of reproductive technologies, surrogacy, and adoption.

As more families reflect ethnic, religious, and class differences, as well as complex structural variation, members confront challenges in incorporating significant differences into their management of family identity. Many families are defining themselves, for themselves and others, through their interactions. The more complex the family

membership, the more family identity becomes dependent on discourse or talk among family members and between family members and outsiders. Through such talk, family members coordinate their understandings of how their family is formed and maintained.

David Olson's research reveals three central dimensions of behavior that family members must manage: cohesion, adaptability, and communication. Cohesion involves emotional bonding as well as acceptable levels of autonomy that family members experience. Cohesion is represented in areas such as adult partner relationships, family members' involvement with each other, subgroups and coalitions, and internal and external family boundaries. Adaptability, or a family's capacity to alter rules, roles, and power in response to stress, is evidenced through dimensions such as leadership, discipline, and negotiation. Communication facilitates the maintenance or change of patterns within these two dimensions. This entry focuses on the role of communication patterns across all stages of family life.

Family Communication Patterns That Influence Meanings

Families actively engage in *meaning making*, or creating shared understandings, of how members view the world. Shared meanings develop over time through the continuous interpretation of, and response to, interpersonal messages and family members' reactions to life events. Family meanings establish family identity as they evolve into patterns over time. Family communication patterns tend to move across generations, unless deliberately rejected. Each generation, consciously or unconsciously, teaches the next generation practices for managing issues such as those involving intimacy, conflict, and stress.

Family communication patterns can be traced across three and four generations on genograms (family trees depicting family relationships and interaction patterns). Unique family heritages and cultural norms influence the communication patterns passed through generations. Family meanings commonly emerge from patterns in the following areas: communication rules, narratives, and rituals.

Family Communication Rules

Every family develops and conveys rules for its members. Rules involve shared understandings of what communicative practices are appropriate in various circumstances. Relational rules indicate expectations for behavior between and among family members. Children are taught what can be talked about, how it can be talked about, and who is allowed to hear. As partners form new families, they often struggle with coordinating the different rules they learned in their previous family experiences. Rules are learned implicitly (e.g., a parental disapproving look) as well as explicitly (e.g., "Never tell anyone Dad got a DUI"). Cultural norms influence family communication rules; children raised in Chinese families may learn different rules for disagreeing with parents than do children raised in Jewish families.

Secrets, a critical subset of family communication rules, involve information that one or more members purposely conceals. Rules for creating, keeping, and revealing secrets shape family interaction patterns, establishing boundaries between the family and the outside world or between individual members. Family secrets range from causing pleasurable surprise to poisoning relationships. Secrets serve functions such as bonding members, maintaining relationships, or defending the family. Secrecy is often created or revealed at periods of family change, such as the birth of a child or a divorce. Secrets may be maintained across generations. For instance, families of Holocaust survivors often operate based on rules of silence regarding relatives' experiences; similarly, parents diagnosed with HIV struggle with whether to tell their children.

Family Narratives

Research suggests that family stories serve many functions: remembering key persons and events, creating a family identity, teaching values and expectations, socializing new members, providing family stability by connecting generations, and entertaining members. Stories remind members of their heritage and reinforce family themes, such as "The Carsons Stick Together." For examples, survival narratives frequently are found in stories about overcoming adversity, such as immigration stories. These are told to the next generations, reinforcing family roots and values. Many family

stories are lost because of circumstances such as divorce or relational distancing. Historically, secrecy developed around issues such as adoption, criminal behavior, and violation of family values; the silence results in lost or inaccurate stories. Researchers who study how family members tell their stories report different styles of storytelling by married couples, ranging from skilled joint performances to individual performances marked by member disagreements. A recent study of family triads telling stories revealed that the most common family narratives depicted dealing with stress.

Family Rituals

Family rituals communicatively connect and maintain relationships while reinforcing family values. Rituals may involve two or three members, such as a father and his young children making pancakes together every Sunday morning, or extended family groups, such as birthday gatherings. Additionally, rituals connect families to cultural practices, for example, Thanksgiving dinner or Kwanzaa. Intergenerational rituals may involve attending sporting events or sharing a summer vacation home, which connect generations. Frequently grandparents develop their own rituals with grandchildren. Weddings, graduations, and funerals serve as family ceremonies providing opportunities for significant member interaction involving storytelling, reminiscing, and catching up.

Family rituals may create complications. Many newly formed blended families struggle to learn how to selectively enact some of the family traditions from the former family while developing their own identifying rituals. Although family rituals are usually positive, families may sometimes enact negative rituals, such as when one or more members are repeatedly hurt by others' behavior. When living with alcoholism, drug abuse, or aggression, members often encounter painful ritualistic arguments or physical violence. Ritualistic verbal or physical abuse can damage adult-child or sibling connections.

A central communicative function of family life is to manage predictable tensions or relational dialectics. A dialectic approach to family communication suggests family life involves managing constant tensions as members manage their relationships through their give-and-take on multiple competing

issues, such as separateness and connectedness, novelty and predictability, and openness and closedness. These tensions raise questions such as the following: How much openness or privacy works for each of us in this relationship? What levels of closeness or distance create a workable relationship for us? Family members manage dialectical tensions through a variety of communicative strategies. These strategies include choosing one of the opposing poles (e.g., disclosing everything and rejecting personal privacy), adapting behavior to varying contexts or circumstances, or switching between one pole and the other. Although most dialectical family research addresses interfamily interactions, other tensions may play out as a sub-unit (e.g., partners) relates to outsiders, such as a boss or friend, while managing tensions around personal disclosure or spending time with others.

Relational Maintenance and Intimacy

Maintaining family relationships is a significant communicative task that involves keeping a relationship in satisfactory condition or repairing a damaged relationship. Usually family members interact according to patterns without consciously considering their behaviors. Occasionally, members consciously enact certain communication behaviors to nurture and maintain relationships. Research demonstrates that people who engage in ongoing relational maintenance behaviors, or make efforts to support the relationship and each other's needs, tend to stay together and find greater satisfaction. Studies of marital maintenance by Daniel Canary and Laura Stafford reveal five key maintenance strategies—(1) expressing positivity and avoiding criticism, (2) being open or self-disclosing and sharing feelings about the relational issues, (3) giving assurances of commitment to a future connection, (4) sharing social networks of family and friends, and (5) sharing tasks. Many of these strategies can apply to other family ties within the immediate or extended family. Siblings may work to maintain their relationships through strategies such as visits, humor, aggression, and role modeling. John Gottman's research reveals that marital maintenance can be helped by a "5:1 magic ratio of positivity to negativity." In other words, partners in stable couples

were characterized by making five times more positive communicative behaviors toward each other than negative behaviors.

Intimacy involves a strong sense of commitment, connection, and devotion. Family members develop intimate relationships that reflect the nature of their bond (e.g., grandparent–grandchild) and the caretaking behaviors each person brings to their relationship. Developing and maintaining such intimacy requires effort and attention to the needs of the other. For example, sharing relational currencies, or messages that express affection, contributes to family intimacy. Relational currencies arise from family-of-origin patterns for sharing affection and may differ across family life stages and cultures. Some currencies, such as positive verbal statements, listening, touch, and adult sexuality, send direct messages about the level of caring. Other currencies, such as money, favors, staying in touch, or spending time together, require more careful interpretation. Satisfaction comes when both parties agree on the meaning of the act—when a sister understands that her brother’s regular e-mails are a way of showing he cares. However, if the sister needs to hear compliments or endearments from her brother, his desire to demonstrate care via e-mail is lost.

Voluntary self-disclosure, another example of a relational currency, may deepen relational ties among family members old enough to appreciate the risk and level of commitment involved. Adult partners build intimate ties, in part, by sharing deep feelings with each other and expressing honestly their positive or negative feelings about issues that affect the relationship. In functional families, parents and children learn to share more personal and private information during periods of late adolescent and adulthood. Openness may result in feelings of sadness or anger in other members, necessitating discussion and, possibly, forgiveness. The act of forgiveness affects relational longevity and connection. Sometimes forgiveness implies an explicit renegotiation of a relationship through metacommunication, or communicating about the way one or more family members communicate.

Family Typologies

Family typologies provide one way to generalize about groups of families with similar characteristics.

Early research identified *open*, *closed*, and *random* family types. Closed families are characterized by predictability and regularity, open families by flexibility and variability, and random families by fluctuations and unpredictability. More recently, Mary Anne Fitzpatrick and L. David Ritchie described four types of families based on the family’s orientation to conformity and their orientation toward open communication. Orientation toward conformity and orientation toward communication can be thought of as being on two axes. *Consensual* families are high in both conversation and conformity strategies. Their communication is characterized by pressure for agreement after an expression of ideas or desires. *Pluralistic* families are high in conversation and low in conformity, support open communication, and avoid pressuring for conformity. *Protective* families resist open communication and value regulation and conformity. Finally, members of *laissez-faire* families value individualism, interacting little because of their pattern of nonconformity and their lack of support for conversation. Such family communication styles affect the adults’ partnering and parenting practices as well as children’s communication practices.

Conflict and Challenges

Conflict, a source of distress and growth, is a necessary and predictable part of family life. A total absence of conflict may lead to negative long-term consequences because differences are suppressed. Everyday family life often involves the exchange of hurtful messages such as accusations, teasing, or negative evaluations. Family members may respond to hurtful messages through confronting the statements, acquiescing, or appearing invulnerable. Recurring patterns characterize marital and family conflict; couples conflict over the same issues approximately 70 percent of the time. Nonproductive, repetitive family conflicts tend to move through stages beginning with a predictable trigger, followed by frustration awareness, active confrontation, temporary solution or nonsolution (e.g., leaving the room), and routine follow-up behaviors. Gottman’s research identifies a pattern of marital distress and dissolution beginning with criticizing, followed by contempt, defensiveness, and stonewalling, although over time couples may

display certain distress patterns more frequently. Unless outside circumstances change or members work together to eliminate such patterns, they will continue indefinitely. Conflict produces growth when members can manage their differences with respect and flexibility. The capacity to forgive and to accept forgiveness remains central to ongoing marital and family satisfaction.

Power, Influence, and Decision Making

Families' daily interactions are affected greatly by how power and influence are used and how decisions are made. Each family member holds some power over his or her and often others' behavior. This power is generally mutually constructed—for example, a child may have power over his parents by acting out to get attention. If the parents instead choose to ignore the child's poor behavior, the child loses power. Each family member may rely on different resources for power. A father might use his role as breadwinner to assert power over the family's financial decisions; a child might discover that her ability to make others laugh gives her power to avoid punishments for breaking rules.

Influence, or using power to try to change or modify another family member's beliefs or behaviors, is central to a family's daily interactions. A parent may try to persuade an adult child to bring her husband and children home for Christmas, or a child may try to persuade an older sibling to lend him money. Researchers have identified a variety of strategies used in trying to influence family members, including bargaining, begging, and emotional appeals through pouting or "sweet talking."

Family life requires frequent decision making. Smaller, routine decisions (e.g., which brand of orange juice to buy) may be made routinely by a family member assuming a certain role. Other, larger decisions (e.g., where to go on a family vacation, how to spend an income tax refund) may be made only after much discussion and input from various family members. Decisions may ultimately be characterized as any of the following: (a) consensus—all family members agree on the final decision after discussion and often compromise; (b) accommodation—some family members just "give in" to others to end the discussion; or

(c) *de facto*—no agreement is reached and one family member acts despite that.

Family Communication Challenges

Recent developments in areas of health and technology confront many families with unforeseen challenges. In particular, families face challenges in managing members' health as life expectancy increases. Currently, communication researchers are studying the ways in which family members discuss health-promoting practices (e.g., brushing teeth and exercising) and health risk-reduction behaviors (e.g., moderation in drinking or practicing safe sex). An examination of a family's health rules and how those rules guide adolescent behavior reveals that highly expressive families rate lower on health compliance and conformity-oriented families rate higher on shared understanding of health rules.

Ongoing research on marital couples reveals that the quality of married couples' interactions affects physical health through changes such as blood pressure or heart beats per minute. Conflict has a particularly negative effect on wives' health. Research reveals identifiable communication patterns, such as verbal (name calling) or nonverbal (eye rolling) displays of contempt that characterize families affected by alcoholism, drug abuse, eating disorders, or mental illness. Any time a family member is diagnosed with a disease ranging from cancer to Alzheimer's disease, other family members experience pressures from new roles, such as acting as a patient advocate or becoming a caregiver. Ongoing genetic research affects family interaction. Family discussions about genetic risk center on identifying who is at risk, deciding whether and how to disclose this risk to family members, and supporting family members managing genetic diseases.

Technological advances, such as the Internet and other interactive technologies, have altered family life significantly. Traditional family hierarchical structures are experiencing role reversals as more children develop skills and acquire information unfamiliar to their parents. Adolescence and young adulthood no longer imply powerful generational separations as cell phones, e-mail, text messaging, and tracking devices increasingly

involve parents and offspring in continual interaction. As adult siblings and extended family members develop unique ties through technology, a key adult no longer must serve as the communication hub of an extended family network. Unique family applications of technology include sharing family news or health information on family Web sites, blogs, or through round-robin e-mails. Research indicates that some family members use e-mail instead of face-to-face interaction to address painful topics or conflicts.

Family communication patterns and practices vary by a family's developmental stage, culture, and stresses. As families are confronted with the challenges of the 21st century, they will need to commit to making efforts to sustain their relational ties, engage in communication strategies that reinforce their family commitments, and evidence a willingness to adapt to cope with the challenges that they encounter

FAMILY DATA, ANALYSIS OF

Family data analysis involves the application of statistical analysis methods to those particular relationships found in families; for example between spouses, parent–child, and sibling relationships. Most research in the social sciences considers the outcome for only one individual; for example, studies of childhood depression. In this case, standard statistical analyses can be used to test hypotheses. However, in studies of the relationships among family members, interdependence can make the outcomes of different family members systematically similar to—or different from—one another. When the outcomes of two or more people are being studied and those outcomes are correlated, researchers say that there is non-independence of observations. *Independence of observations* is a requirement for most common, statistical methods, so special analytic methods are often required for family data. This entry focuses on the unique characteristics of family data, sources and patterns of nonindependent outcomes, and models for the statistical analyses of these patterns.

Family Roles

In textbooks about families, one of the first issues considered is “What is a family?” This discussion often leads to controversy regarding which roles should be included in the definition of the family. Mother, father, and child are the conventional roles associated with family, but gay and lesbian

couples also raise children together; some families include adoptive or stepparents, natural siblings, and stepchildren; and many households consist of single parents. For the purposes of this discussion, it is not important to define the family by specific roles, but the fact that there are distinguishable roles remains important. Most family research is organized around family roles (e.g., mother, father, parent, child, and sibling).

Levels of Analysis

Statistically, family group data are typically studied as a two-level system. The family as a group is considered level 2, and the individuals within the family are considered level 1. Put differently, individuals are nested within the family, just as students may be said to be nested within a classroom. This is important statistically because the sample size differs at the two levels. Fifty couples may be observed in a study of marital relationships, a relatively small sample, but there would be 100 individuals in the study, a relatively large sample. The ability to detect a significant relation between two variables (i.e., the statistical *power* of the analysis) depends heavily on the sample size. The level at which a problem is analyzed, for example group versus individual, is called the *level of analysis*.

In family research, the level of analysis is usually the family or the *dyad* (a two-person group) even though the *unit of analysis* (i.e., the level at which measurements are made) may be the individual (e.g., a personality measure) or a particular relationship (e.g., how much one family member trusts another). This is so because, as mentioned earlier, the outcome scores of individuals within the group are usually correlated or nonindependent. To the extent that the scores are correlated, they cannot be counted as two separate individuals statistically (i.e., the *N*, or sample size for the analysis, must be adjusted). Some statistical procedures (e.g., *hierarchical linear modeling*) make these adjustments automatically and are capable of simultaneously testing predictions at both the group and individual level. It is important to include enough families or dyads in a sample so that effects at the group level can be reliably estimated.

Sources of Nonindependence in Family Data

Historically, the fact that family members' scores are correlated has been considered a nuisance because ordinary statistical procedures cannot be used. To avoid the issue, researchers will sometimes combine the outcomes of all the individuals at level 1 (e.g., husbands and wives) and just analyze the data at the group level. Unfortunately, when there is an outcome for more than one person in the group, such a process sacrifices information about individual-level effects. A more interesting and informative approach is to *model* the sources of the nonindependence within the analysis. To model the sources of nonindependence means to include in the analysis any variable that might be causing the scores to correlate. Including such variables within the analysis has the effect of controlling for these factors so that they do not bias the statistical results.

There are three primary sources of nonindependence in family members' scores; common fate, partner effects, and feedback loops. *Common fate* occurs when two people are both affected by the same factor. For example, a parent and a child may be similar in some respect because they share a certain gene. After controlling for the effect of this gene, their responses (e.g., friendliness toward each other) may no longer be correlated. By modeling factors that cause nonindependence, two things are achieved. First, the explanation for the similarity of their scores is elucidated. This may be of key theoretical importance in itself. Second, the effects of other factors that may affect fathers' or children's friendliness toward each other (e.g., personality traits) can be estimated without bias. To have an unbiased estimate of the effect of one variable on the outcome, the effect of other causes of the outcome must be controlled. This is one reason why the guidance of a good theory is so important. Theory tells us what variables need to be controlled in the model.

Partner effects occur when the behavior of one individual in the family is affected by the behavior of another individual in the family. In the previous example, the child may have been friendly toward the father because the father has the personality trait of agreeableness. The effect of the father's agreeableness on the child's friendliness is a partner effect. If father's agreeableness makes him

friendly toward the child and also makes the child friendly toward the father, then the father and child friendliness scores would be correlated and nonindependent. To obtain an unbiased estimate of the partner effect for father on child, other factors affecting child friendliness must be included in the model. One of these factors may be the child's own agreeableness. When a person's own characteristics predict their own outcome, it is called an *actor effect*. In general, when one wants to test for partner effects, actor effects should be included in the model, and when one wants to test for actor effects, partner effects should be included in the model. When theory suggests that both people affect each other (i.e., there are partner effects for both individuals), then actor effects for both people should also be included in the model. A two-person model with both actor and partner effects for each person (e.g., parent and child) is called the *actor-partner interdependence model*, one of several techniques for dyadic data analysis.

In all likelihood, researchers will not know or be able to measure all factors that may make two family members' scores correlated. When this is the case, the *residual variances* (i.e., the variance in the dependent variable scores that is not explained by the independent variables) will still be correlated. Some statistical procedures (e.g., *structural equation modeling*) allow one to include these residual correlations in the model. Inclusion of the residual correlations in the model helps control for these unknown sources of nonindependence so that the estimates of the actor and partner effects and the effects of other independent variables are not biased.

Feedback processes are a third source of nonindependence in family members' outcomes. Feedback occurs when each person's outcome has a direct effect on the other person's outcome. For example, if the child is friendly toward the father because the father is friendly toward the child, and correspondingly, the father is friendly toward the child because the child is friendly toward the father, there is a feedback loop. In the actor-partner interdependence model, it may be that only one of the partner effects is significant (e.g., father influences child), so there is not mutual influence. When there is feedback, mutual influence exists by definition. Feedback processes can be modeled statistically, but the procedures can be quite

complex. A simple version of such an analysis in two-person relationships is called the *mutual influence model*. Imagine that the father's agreeableness does not affect the child's friendliness but only affects his own friendliness. In other words, there is an actor effect but no partner effect. Imagine also that this is true for the child; that his or her agreeableness affects his or her friendliness toward father, but does not affect father's friendliness. In this situation, it is possible to test the mutual influence model to see whether each person's friendliness affects the other's friendliness. In general, if a researcher expects partner effects, the mutual influence model should not be tested. Advanced statistical methods (i.e., structural equation modeling or hierarchical linear modeling) are used to test this model. The actor-partner interdependence model and the mutual influence model are generally applied to data from two-person relationships or dyads. When studying family groups that include three or more people (e.g., mother, father, and child), the Social Relations Model is generally more appropriate.

The Social Relations Model

When relationship specific measures (e.g., interpersonal trust) are taken from each family member about his or her relationship with each of the other family members (i.e., a *round-robin design*), the Social Relations Model (SRM) can be applied to the data to obtain interesting and important information about patterns of family relationships. According to the SRM, one person's relationship with another family member is a function of characteristics of the family as a group (*a family effect*), characteristics of the person from whom the observation is taken (*an actor* or *perceiver effect*), characteristics of the partner in the relationships (*a partner* or *target effect*), characteristics of the unique relationship of the particular actor to the particular partner (*a relationship effect*), and errors of measurement. For example, how much the mother trusts the father will be the result of the overall level of trust in the family (the family effect), how trusting the mother is of other family members in general (mother's actor effect), how much the father is trusted by other family members in general (i.e., how trustworthy he is, a

partner effect), and the degree to which mother's trust of father is unique to her relationship with him (the mother-to-father relationship effect). Each relationship in the family is partitioned into these components, so that in a two-parent two-child family, there will be 1 family effect, 4 actor effects, 4 partner effects (one of each for mother, father, older child, and younger child), and 12 relationship effects (one for each person's relationship with each of the other 3 family members).

The SRM also tests whether people get what they give in their family relationships (i.e., *reciprocity*). Using a sample of families, the correlation of the actor and partner effects for each role (for example, mother's actor effect and mother's partner effect) tests reciprocity for individual roles in the family (e.g., are trusting mothers trusted by other family members?). Similarly, the correlation of relationship effects for each dyad in the family tests whether there is reciprocity that is unique to particular relationships (e.g., if mothers trust fathers, do fathers trust mothers?). It is also possible to test similarities between members of the same generation by correlating their actor or partner effects. For example, a negative correlation of mother and father partner effects for ratings of "influenceability" suggests that the more one parent is experienced as influenceable (or permissive), the less the other parent is experienced as influenceable (i.e., more strict). The family SRM provides a comprehensive snapshot of the family system, but it can only be tested using advanced statistical methods (e.g., structural equation modeling or hierarchical linear modeling). However, it is the most sophisticated model of family relationships that has ever been specified in a measurable, refutable, manner.

FAMILY FUNCTIONING

When discussing the institution of the family, in general terms, or individual families in specific terms, the discussion often hinges on issues surrounding the structure of the family and how the family functions. *Family structure* refers to the type of family being discussed, with a wide variety of terms used to describe family structure. *Family functioning*, on the other hand, refers to the roles family members play and the attitudes and behaviors they exhibit in their relationships with each other. This entry focuses on family functioning, the difficulties in studying it, and the range of frameworks that have been developed for understanding it, with special emphasis on the Circumplex Model and the Family Strengths Framework.

Toward a Better Understanding of How Families Function

Studying how families function poses significant challenges for researchers because so much of what happens in families goes on, literally and figuratively speaking, *behind closed doors*. To compound this problem, many people are often reluctant to invite social and behavioral scientists into this most intimate of environments. The difficulty for researchers is magnified when the family behavior under study is especially intimate, stigmatized by society, or indicative of significant family problems that members are not especially eager to expose. In short, people do not always tell the truth when being interviewed and do not always act "normal" when being observed.

Investigators interested in how families work, fortunately, have proven to be creative in devising ways to navigate the closed and private nature of

family functioning. These research methods for developing a better understanding of family relationships can be broadly divided into studies from an *insider* perspective or from an *outsider* perspective. An insider perspective when studying family functioning relies on what family members themselves have to say about how well the family is functioning. An outsider perspective emphasizes what professional observers and analysts have to say about the family after observing the family in action or studying written testimony or test results. Both insider and outsider perspectives have their strengths and weaknesses, and studies marrying the two approaches can yield important findings. In these types of studies, the investigators look closely at what family members themselves have to say about the family, they observe the family in action in a relatively normal environment, and the investigators make their own judgments about the family's functioning, based on professional training and experience.

In the final analysis, families are remarkably difficult to study because of their closed nature and the challenges of obtaining valid data (which actually measures what researchers think they are measuring) and reliable data (which passes the test of being able to stand up over time, even though by nature families are likely to be constantly evolving and changing). These difficulties, fortunately, make the work of family researchers enduringly fascinating.

Conceptual Frameworks for Understanding Family Functioning

Theoreticians, researchers, and practitioners have developed many conceptual frameworks to help us better understand family functioning. Several that are relatively prominent today will be briefly discussed here.

Family Systems Framework

The family systems framework for understanding family functioning is especially popular today among theoreticians and researchers and valued by many family therapists working to help strengthen relationships. From a systems perspective, everything that happens to any family member has an impact on everyone else in the family. Besides

being a system in itself, families live in a hierarchy of interconnected systems: The family system is connected to systems in the community (school systems, business systems, work systems, medical systems, and so forth); and the family system is connected to systems on the national and international level as well (government systems, justice systems, political systems, economic systems, and so forth).

Family systems theorists describe families that are relatively flexible and capable of making changes, calling these *open* or *morphogenic systems*. Other families avoid change and struggle to always maintain the status quo. These families can be labeled *closed* or *morphostatic systems*. Using family systems terminology, couples and families often struggle to maintain a workable balance between separateness as individuals and togetherness as a group. Some members strive for a greater sense of closeness, whereas other members seek more time outside the group to develop their own sense of individuality.

Communication is especially important in families, and systems theorists describe feedback loops that can either be positive or negative. *Positive feedback* in families is intended to create change, whereas *negative feedback* minimizes change and keeps things the same.

Family Development Framework

The family development perspective was created to help researchers understand how family members deal with various roles and developmental tasks within the family as it moves through relatively predictable stages. In the 1950s, Evelyn Duvall originally identified eight stages: (1) the newly married couple (adjusting to each other, adjusting to each other's family of origin), (2) child-bearing, (3) preschool children, (4) school-age children, (5) teenagers, (6) launching youth into adulthood, (7) middle-aged parents (refocusing on marriage), and (8) aging family members (adjusting to retirement, selling the family home, coping with death and living alone). Later theorists focused on the considerable diversity of experience regarding couple and family development, noting that not everyone marries or has children and that divorce, single parenthood, and remarriage make matters much more complex when trying to

describe relatively predictable stages. Other theorists have created stage theories with as few as 4 stages and as many as 24. Though the family development framework cannot adequately describe the complexity of life in families today, thinking about families from a developmental perspective does help us understand that couple and family relationships are likely to change over time and these changes are often linked to common events in many people's lives, such as marriage, parenthood, divorce, retirement, and so forth.

Symbolic Interaction Framework

A family is *a unity of interacting personalities* from the symbolic interaction perspective, which emphasizes the importance of individual perceptions of the interactions that occur. Family members are likely to see what is happening in the family in different ways. Within the family, each member occupies a position or positions (e.g., first child, father, grandparent) to which a number of roles are assigned (e.g., role model for younger children, provider, caretaker). Each individual perceives the assigned role(s) and role expectations held by other family members in her or his own way. This attention to shared meanings and interactions helps us understand why, for example, parents and adolescents perceive communication and family dynamics differently. It also suggests that family functioning cannot be understood simply by observing a family. To understand what is happening in the family, the investigator needs to learn how each individual's *definition of the situation* may differ from everyone else's definition.

Another concept derived from this framework is the *looking-glass self*, the notion that your feelings about yourself are derived from how others react to you. One's self-concept emerges in childhood as a reaction to others' perceptions of who you are and your value in the family. A child who is devalued by parents and siblings is likely to feel worthless inside.

Feminist Framework

Women are exploited, devalued, and oppressed, according to the feminist perspective, and societies around the world should commit to equality for men and women in political, economic, and

social spheres. Family functioning is a key area for feminist-oriented researchers, focusing on ways in which women are sometimes forced into roles that as individuals they might not wish to play. When the current wave of feminist thinking in the United States began in the 1960s, it was seen as *normal* for women to want to marry, have children, and stay at home to focus on marriage and motherhood. With the publication of Betty Friedan's groundbreaking book, *The Feminine Mystique*, a national and international discussion began once again regarding Friedan's belief that women needed a more active voice in decisions that affect them.

Friedan was reacting, in part, to a culture that sanctified the thinking described by the *structural/functional framework* for understanding family functioning, which was developed in the 1950s. This approach, created by academics such as Talcott Parsons, assumed that the family was most functional when husbands played the *instrumental role*, being in charge of tasks, and wives played the *expressive role*, being nurturing in the home.

Some men today are offended and feel threatened by feminist thinking, which argues that women have the right and responsibility to grow and develop without regard to social traditions that may try to dictate what is proper *feminine* behavior. On the other hand, other men today feel they have received significant benefits from feminist thinking in terms of family relationships. These men argue that feminism has encouraged men to express their feelings, to share wage-earning responsibilities and power with their partners, and to focus less energy on winning in their careers and more energy on loving their children and wives. Two wage-earners in a family reduces the pressure wage-earners often feel, and two actively involved coparents ease the strain while giving both parents the opportunity to enjoy seeing children grow.

Social Construction Framework

Human beings are profoundly immersed in a social world, and how we think about this world is a product of our social interactions. Similar to symbolic interactionism, social construction theorists believe that because the self is a product of social processes, individuality is difficult to develop

because our lives are caught up in a social environment. Social construction theories are closely related to current postmodernist and multicultural intellectual movements. Postmodernism posits skepticism in regard to questions of truth, meaning, and historical interpretation. Our view of the world is colored by the social environment in which we live. In effect, we do not see the world *as it is*; rather, we see the world *as we are*, but we fool ourselves into believing that we really see the truth with a capital T.

Regarding family functioning, then, the truth about who a particular family is and what the family does can change as time passes. A troubled family can learn to create a new, more positive story about who the family is and where family members are going in life. *Narrative therapy*, an approach to family therapy that grew out of social constructionist and postmodernist thinking, helps a family develop a new way of looking at itself and creating a new story line for a better future.

From a social constructionist perspective, this encyclopedia entry is not necessarily the truth about family functioning, but more realistically speaking simply the work of three family scholars who have spent a good deal of their lives observing, thinking, reading and writing about families. This entry, thus, is colored by the experiences of the writers and by the social environment in which they have lived, and another team of writers would most likely come up with a considerably different perspective.

Circumplex Model of Marital and Family Systems (Couple and Family Map)

Heavily influenced by family systems theories, David H. Olson and his colleagues created the Family Circumplex Model, also described as the Couple and Family Map. This framework, which is illustrated in a graphic, map-like form, describes how families function (see Figure 1). This perspective uses three broad dimensions: cohesion, flexibility, and communication. The basic hypothesis of the Family Circumplex Model is that families that are *balanced* (central areas of the model) tend to function better than families that are *unbalanced* (more extreme areas of the model). Another hypothesis is that balanced families tend to have

better communication compared with unbalanced families. More 1,000 studies have been conducted using the self-report assessment called Family Adaptability and Cohesion Evaluation Scales (FACES) and the observational Clinical Rating Scale that strongly support these hypotheses.

Cohesion is a feeling of emotional closeness with another person. Cohesion is achieved by balancing separateness and togetherness. Extremely low cohesion in a couple or family is called *disengaged*. Extremely high cohesion is called *enmeshed*. Olson believes that healthy couples and families are balanced in the amount of cohesion they demonstrate. Couples and families often struggle to maintain a workable balance between separateness and togetherness.

Flexibility, the second dimension in the Family Circumplex Model, focuses on a balance between stability and change. Flexibility is the ability of the family to change over time. Families need a basic foundation of beliefs and behaviors that give them stability. But they also need to be open to change, especially in a time of crisis when a change in thinking and actions can be of benefit. The two extremes on the dimension of flexibility are a *rigid* family system, indicating a low degree of change in the family, and *chaotic* family system, indicating an extremely high degree of change. Couple and family systems that have a more balanced level of flexibility tend to function better over time.

Communication, the third dimension of this model, is the grease that smoothes frictions between family members. As the reader will recall, cohesion and flexibility are best in medium doses, not too much and not too little of each quality. Communication, on the other hand, is directly related to the strength of the couple and family relationships.

The findings of two other prominent research groups bear mentioning here, in relationship to Olson's work: the Beavers System Model focusing on family competence and the McMaster Model focusing on healthy or normal families. Both approaches have long, rich traditions. The Beavers Model looks at many dimensions of family functioning, including the following: centripetal/centrifugal interactions (interactions that either push family members apart or pull them together), closeness, parent coalitions, autonomy, adaptability, egalitarian power, goal-directed negotiation,

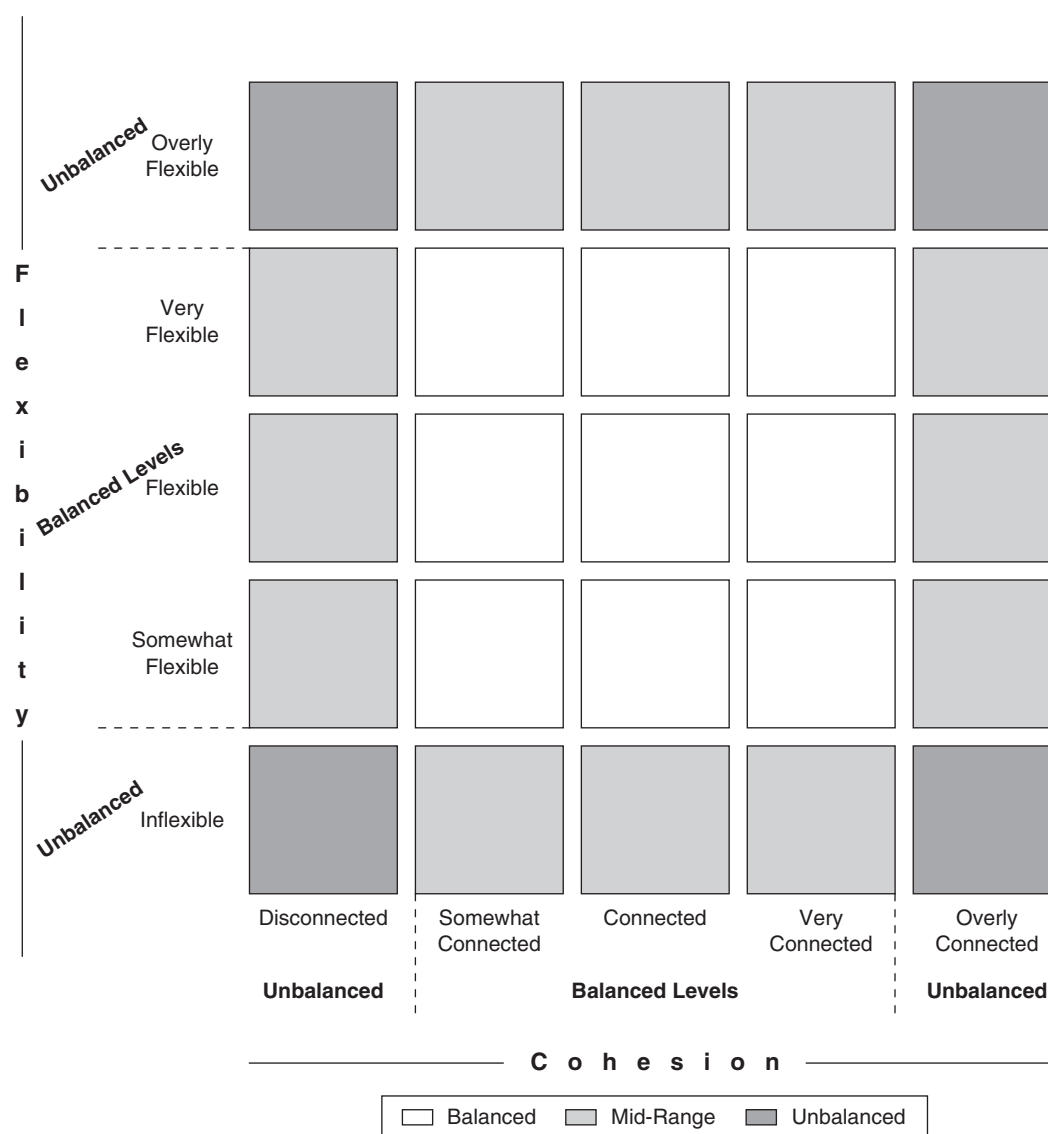

Figure 1 Circumplex Model of Marital and Family Systems

the ability to resolve conflict, clarity of expression, range of feelings, openness to others, and empathic understanding. The McMaster Model team posits that studying healthy or normal family functioning may be “a fool’s errand” because of the complex nature of family interaction, and focuses on the dimensions of affective involvement, behavior control, and communication. In this context, note the similarity of the elements of family functioning under study by the different research teams. Though each team approaches the task at hand from different perspectives and uses different

research techniques, the basic elements of healthy family functioning deemed worthy of study by each group of researchers are remarkably similar.

Family Strengths Framework

The family strengths approach to understanding family functioning has roots in the work of Herbert Otto in the 1960s and was further developed by Nick Stinnett, John DeFrain, and many colleagues. The researchers have focused on better

understanding the strengths of families that describe themselves as strong, happy, and satisfied with their life together, and believe they love and care for each other well. So-called strong families exhibit six major clusters of qualities:

- *Appreciation and affection for each other:* friendship, respect for individuality, playfulness, humor.
- *Commitment to the family:* trust, honesty, dependability, faithfulness, sharing.
- *Positive communication:* giving compliments, sharing feelings, avoiding blame, being able to compromise, agreeing to disagree.
- *Enjoyable time together:* quality time in great quantity, recognizing good things take time, enjoying each other's company, sharing fun times.
- *Spiritual well-being:* living a meaningful life, hope, faith, compassion, shared ethical values, oneness with humankind, oneness with the world.
- *Ability to manage stress and crisis effectively:* adaptability, seeing crises as challenges and opportunities, growing through crises together, openness to change, resilience.

Today, this model has evolved into the International Family Strengths Framework, which demonstrates how family strengths, community strengths, and cultural strengths are woven together in a seamless fabric: Strong families contribute in positive ways to the health of the communities in which they live and the cultural values of the nation of which they are a part. Likewise, the health of the nation and local communities is essential to the healthy development of individual families. Family strengths researchers argue that the family, in all its remarkable diversity, is the foundation of all known societies in the world; that family strengths, community strengths, and cultural strengths are remarkably similar from country to country; and that these similarities give human beings common ground for creating international relationships and organizations that support the well-being of families worldwide.

FAMILY LIFE CYCLE

Family scholars from sociology, psychology, demography, and economics have employed the concept of the family life cycle (FLC) to examine family relationships. The concept provided researchers with a meaningful way to look at how families changed over time by outlining a series of stages through which families passed across the life course. Although there were different versions of the FLC model in terms of the number of stages proposed, most included the major transition points in the formation and dissolution of the family such as marriage, childbearing, childrearing, empty nest, and widowhood. A family's location in the family life cycle was thought to influence family interaction patterns and, hence, members' satisfaction with the quality of their relationships.

Although popular for more than four decades (1947–1990), the concept has largely fallen out of favor as a result of conceptual and empirical problems. Nevertheless, many family therapists continue to use the FLC as a guide to practice and research. Feminist scholars argue that the continued use of the concept is problematic because it stigmatizes those who are not a member of a traditional nuclear family. Proponents of the FLC argue that the concept describes at least half of the families in the United States (i.e., those who are not divorced) and therefore is still useful. Further, depending on how the concept is operationally defined, proponents believe the FLC can be applied to alternative family forms such as blended families and single-parent families.

This entry describes the historical background of the FLC concept, its conceptual and empirical problems, a feminist critique, and concludes with directions for future research.

Historical Background

The original impetus for studying family change was the unprecedented rates of unemployment during the Great Depression. Research by Charles Loomis revealed that changes in family size and composition were correlated with household income. Families were at greatest risk of poverty

when their children were too young to work and when the parents were too old to work after their children had been launched. After World War II, researchers such as Paul Glick, Evelyn Duvall, and Reuben Hill further developed the idea by delineating specific stages that families went through based on family size, births, ages, launching of children, and the retirement of spouses. Early studies found that the length of family stages was related to age at first marriage, duration of childbearing, and number of children. For example, couples that married late in life would be more likely to have children soon thereafter and consequently would not remain in the childless stage of the family life cycle as long as would couples who married early in life. Similarly, couples who chose to have a large number of children would remain in the childbearing stage of the family life cycle longer than would couples who chose to have fewer children.

Early Conceptual and Empirical Challenges

Although it was initially used by demographers for descriptive purposes, family developmentalists continued to advance the concept. The continuing evolution of FLC was met with excitement because it provided a dynamic view of families to replace the previously static one. On the basis of the epigenetic principle of developmental change, families were viewed as going through a sequence of stages over time. Each stage built on the immediately preceding stage. Only after families mastered the tasks specific to one stage could they proceed successfully to the next stage and its tasks. A succession from one stage to the next was considered normal development.

Although widely accepted, the value of the FLC had not been empirically evaluated. When researchers examined it, they were disappointed with the results. For example, one classic study investigated the predictive power of FLC relative to two other measures of family development—marriage cohort and birth cohort—and found that FLC was no better at predicting a variety of variables related to family development. Another classic study found that the relationship between FLC and family variables disappeared when length of marriage or presence of children was controlled.

Further, life-course scholars argued that the FLC perspective failed to recognize that historical events such as wars and depressions could interrupt the timing, length, and sequence of family stages. The developmental approach to the FLC did not address the ways family relationships are influenced by historical context, and other life-course scholars pointed out that calculating the average timing and duration of stages obscured social class and ethnic group variations as well. Further, not all families followed a linear progression through the stages.

Finally, changes in the demography of families also forced a reevaluation of the FLC perspective. Initially, the concept of FLC had been used to examine differences between generations in the timing and duration of major events of a “typical” family. The concept was based on common marital patterns of the time: intact, nuclear families with one wage earner. However, eventually demographic changes challenged the exclusion of stages previously considered atypical. By the 1980s, premarital birth, separation, divorce, remarriage, and single parenting had become commonplace, making it necessary to expand the FLC to include these variations in its stages. However, even when less traditional family transitions such as divorce and remarriage were included in analyses, the findings showed that the FLC explained only a small amount of the variance in subjective evaluations of life.

Significance of FLC for Human Relationships

How useful are the stages of FLC for the study of human relationships? Some say FLC stages are useful if they are considered as guidelines for following the progression of family careers; however, it is important that these stages not be reified. Other family scholars say there is value in searching for common patterns in family life-course stages because they provide an indication of the pressures families face. As families move from one stage to the next, the progression changes role relationships and families must adapt. Consequently, the quality of family relationships, as indicated by such measures as marital satisfaction, can be influenced. Feminists argue, however, that the significance of the FLC is that it stigmatizes those who do not engage in normative behaviors.

The Feminist Critique of FLC

Feminists are critical of the concept of the FLC and its treatment of gender and divorce. They argue that although FLC has been the conceptual model for the fields of family development and family therapy for decades, it is largely mythological.

The FLC perspective assumes that the normative family is intact, White, middle-class, and male-headed; this is the family form against which all others are compared. The FLC approach uses a deficit comparison model, where any variation from the normative family form is viewed as inadequate. Thus, single-parent families are problematic from the FLC approach because it is assumed that women would not choose to raise children alone. Contrary to the FLC model, which views divorce as an indicator of social decline, feminists view female-initiated divorce as a sign of women’s resistance to the oppression they have experienced in traditional families.

Even though family theorists eventually added new phases to the FLC framework to accommodate single-parent families as well as divorced and remarried families, they continued to compare these new family forms to two-parent nuclear families using a deficit model.

Feminists argue that by relying on marriage and the presence of children to define family, the FLC approach eliminated the legitimacy of choosing not to be married or not to have children and be a family. Its emphasis on intact, married, nuclear families disenfranchised the experiences of individuals and families who did not conform to these stages, including those in poor families, minority families, and gay and lesbian families. These latter families are marginalized and deemed deviant by comparison. Thus, the feminists’ critique of the FLC concept echoes those coming from a life-course perspective: The concept ignores the fact that family events are shaped by historical and cultural context. These mounting criticisms led to a severe decline in the popularity and use of the concept.

Conclusion

What is the future of the FLC concept? Recently, the usefulness of the FLC has been empirically

reexamined. New proponents of the concept argue that previous researchers did not adequately test the FLC. Rather than using family-relevant dependent variables, past researchers used the stages in the FLC to predict demographic variables or individual level variables. To provide a true test of the usefulness of the concept, new proponents argue it is necessary to examine the relationship between the FLC and *family* variables. In their reevaluation, the new researchers found that FLC stages did predict family commitment—a family variable—even after controlling for age and length of marriage. But FLC did not predict marital satisfaction—an individual variable—as they expected.

These researchers also suggested that the FLC could be applied to complex, blended families, as well as to single-parent households, if the concept was operationally defined in terms of the age of the youngest child. Researchers stated that because the rearing of young children is extremely time consuming, the age of the youngest child could provide valuable information about the role demands faced by the parent(s). Such an operational definition could also be used with cohabiting heterosexual or gay and lesbian couples that have children. Thus, this research could potentially reinvigorate interest in the FLC concept.

However, feminists argue that even this operationalization of the FLC is problematic because it suggests that adults who are childfree, whether by choice or not, are not part of a family. Feminists point out that the FLC concept privileges the family of procreation over the family of origin. Consequently, childfree individuals are seen as not having a family and as not moving through family stages.

Thus, the challenge for future researchers is to determine whether the FLC can be operationally defined in a way that can accommodate the vast range of family arrangements that exist in today's society.

FAMILY RELATIONSHIPS IN ADOLESCENCE

No aspect of adolescent development has received more attention than family relationships. Much of the research indicates that despite altered patterns of interaction, relationships with family members remain important social and emotional resources well beyond childhood. Yet it is a challenge to reconcile this conclusion with the widespread perception that family relationships decline in quality and influence over the adolescent years. This entry summarizes theories that address the origins of transformations in family relationships during adolescence, followed by a summary of research on these alterations. The entry concludes with an assessment of the impact that changes in family dynamics have on adolescent development.

Theories of Relationship Transformation

Conceptual models of adolescent family relationships vary in whether their primary focus is on the adolescent or on the relationship. One set of theories holds that adolescent maturation undermines

patterns of interaction established during childhood, whereas another set of theories emphasizes enduring bonds that are assumed to be the foundation for continuity in the relationship. Most theories focus on parent–child relationships; less attention has been given to sibling relationships during adolescence.

Theories Emphasizing Individual Change

Maturation models focus on relationship disruptions caused by adolescent physical, social, and cognitive maturation. These models hold that changes in adolescents provoke changes in families. Diminished closeness and heightened conflict are expected to accompany adolescent maturation and continue until parent–child relationships are renegotiated. Sibling relationships may undergo similar transformations.

Puberty is central to many models. Psychoanalytic theorists assume that hormonal changes at puberty give rise to Oedipal urges that foster rebelliousness and distance from the family. Evolutionary views also link puberty to relationship transformations, such that physical and cognitive advances encourage adolescents to separate from the family to seek mates elsewhere.

Other maturation models give cognitive development a central role in relationship change. In these accounts, advances in abstract and complex reasoning foster egalitarian views that are inconsistent with the unilateral organization of relationships with parents and siblings. As a result, adolescents increasingly aspire to reciprocity and equal power, which may create conflict and curtail closeness. Eventually, familial roles are renegotiated to acknowledge the adolescent's enhanced status and maturity.

Systemic theorists argue that as relationships with firstborn children change, so too must relationships with later-born children. According to the spillover model, relationships with later-born children deteriorate and are renegotiated concurrent with (or shortly after) relationships with firstborn children. The Learning-from-Experience Model posits that parents hone their skills with firstborn children and are thus better able to cope constructively with developmental changes in later born children. According to this view, the

magnitude of change in parent–child relationships differs between firstborns and later-borns, rather than the timing of that change.

Theories Emphasizing Relationship Continuity

Alternative models of family relationships focus on forces that promote stability. The most prominent example, Attachment Theory, emphasizes the strong emotional ties between parents and children. As a mutually regulated system, parents and children work jointly to maintain the relationship in a manner consistent with cognitive representations derived from their history of interactions. Attachment in adolescence is different from attachment during earlier age periods, but the functions are similar. Whereas security facilitates exploration of the immediate environment for young children, security affords adolescents a sense of confidence in family support for explorations outside the family, including those that involve the formation of new relationships. Children and parents with a history of sensitive, responsive interactions and strong emotional bonds should maintain these positive features throughout adolescence. Children and parents with a history of difficult, unresponsive interactions should also experience continuity in the quality of their interactions, however unsatisfactory they may be.

Interdependence or social relations models describe close relationships characterized by frequent, strong, and diverse interconnections maintained over an extended time. In an interdependent relationship, partners engage in mutually influential exchanges and share the belief that their connections are reciprocal and enduring. These interconnections are internalized by participants and organized into mental schemas that shape expectations concerning future interactions. High levels of interdependence characterize most adolescent relationships with parents and siblings. As the child becomes more autonomous, the degree to which relationships change depends on the degree to which participants consider their exchanges to be jointly beneficial, which is closely linked to perceptions of relationship quality. Increased conflict may occur in poor quality relationships, along with a decline in closeness, as adolescents express a growing dissatisfaction with treatment perceived

to be unfavorable. High-quality relationships may change little during adolescence, or may even improve, as participants build on beneficent interactions to adjust exchanges in a mutually satisfactory manner.

Patterns of Relationship Transformation

Family relationships vary across the adolescent years in the content of interactions, the distribution of positive and negative exchanges, and the cognitive and emotional responses of individuals. There is widespread acknowledgement that family members experience their relationships differently. A much higher percentage of mother–child interactions fall into the category of mundane socialization than is true for father–child interactions. In contrast, fathers devote a higher proportion of their time with adolescents to recreational activities. Simply put, mothers spend relatively more time telling adolescents to pick up their socks, whereas fathers spend relatively more time in activities that don't involve wearing socks. These distinctions are amplified by the number of children in the household.

Perceptions of sibling relationships vary according to the relative age of the child; older siblings have a wider variety of experiences outside of the household than younger siblings have, which means that the former may place less emphasis on family relationships than the latter. Family members interpret their interactions according to their experiences; fathers minimize socialization hassles with children, whereas mothers invest considerable emotion in mundane interchanges. This means that fathers experience fewer ups and downs in relationships with adolescent children relative to mothers.

Changing Expressions of Closeness

Most families report that parent–child and sibling relationships are quite positive. Of course, manifestations of closeness change as the child matures. Intimacy, as expressed by physical affection, decreases during the transition into adolescence, whereas conversations in which feelings are expressed increase. Companionship is also modified. As children get older, they are more apt to

watch TV with their families and less apt to share meals and go out together.

Adolescents spend more time with their mothers and are more likely to share feelings and disclose personal matters to them. Fathers may be somewhat distant figures, who tend to be consulted primarily for information or advice and instrumental or material support. Sons and daughters have similarly warm relationships with mothers, but fathers are typically closer to sons than to daughters. These commonalities notwithstanding, views of the family are notable for their divergence, particularly during early adolescence. Where mothers and fathers see distinctive relationships with children, adolescents see monolithic relationships with parents. Mothers tend to appraise the family in positive terms, routinely reporting more warmth and affection among family members than do adolescents, which may be an attempt to ward off the decline in maternal life satisfaction that accompanies adolescent detachment.

Younger siblings report greater warmth and affection toward older siblings than older siblings report for younger siblings. Those who perceive differential treatment or favoritism from parents report worse relationships than do siblings who see parental treatment as equal.

Developmental changes in closeness are well documented. Although perceptions of relationships remain generally warm and supportive, both parents and children report that they spend less time together and that they are less likely to express positive emotions across the adolescent years. Relative to preadolescents, adolescents perceive less companionship and intimacy with parents and report lower feelings of acceptance by parents and less satisfaction with family life. Decreases in closeness appear to be steepest from preadolescence to mid-adolescence, tapering off or even rebounding by late adolescence. Warmth expressed by daughters declines more than that expressed by sons, partly because the former start from a higher level than the latter do. Birth order appears to moderate these trends. Firstborn children report the warmest relationships with mothers and fathers across adolescence, but firstborns also report the steepest drops in warmth from early adolescence to mid-adolescence.

Descriptive data on age-related declines in closeness probably overstate the significance of changes

in parent–adolescent relationships. Declining dependence is not synonymous with erosion in the salience of the relationship. It is not uncommon for late adolescents to name a parent as their closest relationship partner. In most cases, parents remain the most influential of all relationships, shaping important decisions that confront children, even as parents' relative authority over prosaic details of adolescents' lives wanes. Thus, adolescents turn to parents for advice about school, work, and careers and expect parents to help them out when significant troubles arise; peers hold sway over issues such as appearance, leisure activities, and media preferences.

Sibling relationships undergo similar transformations. As young people spend less time with the family, closeness between siblings declines. Few adolescents indicate that their most important relationship is with a sibling, yet most adolescents report high levels of interdependence with siblings. These relationships are remarkably resilient; adolescents will frequently turn to siblings for advice and comfort in times of trouble, particularly when experiencing difficulties in relationships with parents or peers. Across the adolescent years, sibling relationships become more egalitarian. Older siblings are often admired by younger siblings, and in these circumstances, they may be particularly salient sources of influence. There is some indication that adolescents are closer to same-sex siblings than to opposite-sex siblings, but the latter may be considered uniquely important because of the advantages they proffer in navigating the currents of romantic relationships.

There is considerable continuity between positive features of relationships during adolescence and those earlier in life, despite the normative transformations of adolescence. Indeed, the best predictor of family warmth during the second decade of life is family warmth during the first. Most families capitalize on greater adolescent maturity by fostering interactions that promote a psychological closeness that is no longer tied to the frequency of interactions. Families with a history of interpersonal problems, however, may lack the adaptive patterns needed for new forms of closeness during a time of relative distance. Longitudinal evidence is consistent with the notion that some families experience greater diminutions in warmth and support than others. Young people who report

high levels of warmth from parents at the outset of adolescence experience little or no decline in perceived support across adolescence, whereas those who perceive low initial levels of warmth report steep drops in subsequent perceived support. Thus, stereotypes of adolescents as uncommunicative, withdrawn, and disengaged from families overstate the case in all but a few extreme instances.

Changing Expressions of Negativity

Conflict, which is ubiquitous in all close relationships, is especially prominent between family members. Surveys of adolescents indicate that disagreements are most common with mothers, followed by siblings, friends, and romantic partners, then fathers; angry disputes arise more frequently with family members than with close peers. Rates of conflict and levels of negative affect are highest in mother–daughter relationships. Most parent–adolescent disagreements concern daily hassles, so-called garbage and galoshes issues; siblings tend to disagree about possessions, control of electronic media, and annoyances. Disagreements between family members are usually resolved through submission or disengagement; compromise is relatively rare. Negotiation is more common with mothers than with fathers; disengagement is more typical of conflict with sons than of conflict with daughters. Adolescents report that most conflicts with parents and siblings have few negative repercussions for their relationships. Disagreements are more constructive when they involve one parent than when they involve both; fathers and sons are particularly likely to alter conflict behaviors in the presence of another parent.

Contrary to popular views, family conflict does not rise and fall across the adolescent years. Instead, the highest levels of conflict are during preadolescence and early adolescence. Evidence from multiple studies reveals linear declines in the frequency of conflict from early adolescence to late adolescence. Significantly, however, the anger associated with these conflicts increases from early adolescence to mid-adolescence, with little change thereafter. Thus, conflict rates fall as negative affect rises, leaving families with the perception of worsening discord. Conflict rates decline more in mother–child relationships than in father–child relationships, but gender does not moderate

changes in affective intensity. Parents appear to become either more skilled or less invested in changes in relationships with later-born children as compared with firstborn children; alternatively, later-born children may learn how to navigate relationships with parents by watching their older counterparts. In any event, second-born children report less conflict during early and mid-adolescence than firstborn children do during these age periods. Less is known about conflict with siblings, although there is some indication that it too decreases during adolescence. Coercion declines in both parent-child and sibling relationships, accompanied by an increase in disengagement and, during late adolescence, compromise.

Important changes in views concerning family authority and decision making stem from disagreements with parents. Across the adolescent years, but particularly during early adolescence, parents and children renegotiate domains of authority. Adolescents come to view an increasing number of issues as personal matters outside of parental authority (e.g., the cleanliness of one's own bedroom), whereas parents continue to see the same topics as matters that fall within their jurisdiction. These disagreements prompt families to renegotiate roles and responsibilities. The upshot is a dilution of maternal authority as mothers cede control over day-to-day matters to their adolescent children. Fathers tend not to be involved in this area of socialization, and their authority over other domains remains relatively undiminished. Not coincidentally, mothers also report the most negative repercussions from conflicts with adolescent children. Parents and children view these developmental trends somewhat differently. Parents may regard changing patterns of interaction as signs of rejection and deteriorating relationships, whereas adolescents may regard them as evidence of enhanced maturity. The fact that parent and child reports of conflict grow more consonant during late adolescence suggests that disagreements, though often unpleasant, play an important role in aligning expectations and facilitating communication among family members.

More than any other form of social interaction, disagreements offer family members an opportunity to reconsider and revise expectations and relationships. Most families successfully meet the challenges of adolescence, drawing on healthy

patterns of interaction and communication established during earlier age periods. Difficult relations during the teenage years are generally limited to families that had difficult relations during childhood—estimates put the figure at somewhere between 5 percent and 15 percent of the population. Families with histories of ineffective communication are at risk for dysfunctional discord as they encounter pressures to realign relationships in response because they lack the resources for constructively addressing the developmental demands of adolescence.

Implications for Development

A large body of literature links parenting practices to maladaptive adolescent outcomes. Antisocial behavior and substance use are best predicted by an absence of behavioral control; self-esteem and an absence of internalizing problems are associated with high levels of warmth and autonomy granting; school grades are uniquely and positively linked to warmth, autonomy granting, and behavioral control. The impact of family conflict appears to vary as a function of the perceived quality of the relationship. Conflict is inversely related to well-being if the relationship is perceived to be poor, but moderate amounts of conflict may be beneficial for those whose relationships are good. The negative tenor of conflicts in relationships perceived to be unsupportive undoubtedly plays a central role in these deleterious outcomes.

Perceptions of differential treatment by parents have an adverse impact on siblings, particularly if that treatment is perceived to be unfair. The quality of sibling relationships suffers as a consequence of differential treatment, and many young people report depressed mood and heightened anxiety. Other aspects of sibling relationships have been tied to adolescent well-being, but the magnitude of these effects tends to be quite modest. Far more important is the quality of the parents' marital relationship. Aside from the infant and toddler years, parents report that the adolescent years take the greatest toll on marital satisfaction. Poor marital relationships tend to adversely affect parent-child relationships, which, in turn, have a debilitating effect on adolescent development.

Marital conflict often leads to conflict between parents and adolescents, and links between marital distress and adolescent internalizing and externalizing problems tend to be mediated by harsh discipline and parent–child discord.

Conclusion

As families adapt long-standing patterns of interaction to the maturational changes that accompany adolescence, communication may falter for a time, only to recover much of its fluency, albeit in a different form. Emotional ties in most families are quite stable. A small minority of families experience significant perturbation, but these households are noteworthy for dissonance before adolescence. Far more typical are families who cope constructively with the challenge of revising relationships during adolescence, setting the stage for interconnections that endure well into adulthood.

FAMILY RELATIONSHIPS IN CHILDHOOD

Among all developmental contexts, families provide the most direct and extensive environment for the growth of children. Families generally encompass the earliest and longest lasting relationships for children. Although each child, and eventually each teenager and adult, holds a different view of his or her family, these important contexts do share certain roles and functions. Common across families are the expectations that children will be cared for and provided with what they need until they become independent enough to care for themselves. Families also share the responsibility of teaching children about their culture and history, often through the sharing of stories, rituals, and traditions. A much more variable function of families is how they fulfill these expectations. The ways in which families accomplish these expectations and functioning largely occurs through family relationships and interactions among family members. The characteristics and qualities of these family relationships are important because of their linkages with children's growth, health, and adjustment, both individually and relationally, across the life span. This entry describes the central relationships of children in families, including interparental (or relationships between parents), parent–child relationships (or children's relationships with parents), sibling relationships (or children's relationships with siblings), and children's relationships with grandparents and other extended family members. In addition, this entry will highlight common approaches or methodologies to studying these family relationships along with major research findings. Finally, future directions in the study of family relationships in childhood are addressed.

Interparental Relationships

The committed relationship between a child's parents, in the form of either marriage or cohabitation, plays a critical role in family functioning and child development. Among parents' many roles in the family, at least among U.S. families, are expectations that they maintain and develop their romantic relationship as a couple and play complementary roles to one another, serving as coleaders of the entire family as they jointly raise their child(ren). The relationship between parents in an intact family sets the stage for the quality of connections among all family members. Interparental relationships directly and indirectly socialize children to how relationships between people function, including those that occur within and outside of the family system.

Substantial evidence indicates that how parents manage differences or resolve the conflicts that arise between them has widespread effects on family relationships and family members. Interparental conflict directly affects children. Partners who consistently resolve their conflicts through hostility, criticism, and anger tend to have higher levels of conflict and issues that remain unresolved and have children who themselves tend to show more anger or withdrawal. Further, children may blame themselves for parents' high levels of conflict or try to serve as resolution mediators, especially when parents argue over childrearing or family-related issues. Conversely, conflict that is resolved, and that does not include high levels of hostility or personal attacks, serves as an example to children that differences between people are manageable and as a model for how their own interpersonal disputes should be handled. Importantly, children who experience most of their interparental conflict handled in this way tend to feel more emotionally secure about their family and themselves.

As interparental relationships demonstrate higher levels of hostility and unresolved conflict, other family relationships such as parent-child relationships and sibling relationships have higher levels of negativity themselves. As examples, marital discord experienced in childhood is associated with greater differential treatment of young siblings (through tendencies to favor one child over another) and with higher levels of rivalry and jealousy among adult siblings. Although parents may

compensate for an unsatisfactory marital partnership by being overly positive with or connected to their child, most family relationships share similar qualities. As the interparental relationship flourishes or suffers, so too will relations among all other family members and subsystems.

Parent-Child Relationships

Relationships between parents and children are nonreciprocal in that parents are expected to fulfill many roles for children, whereas children are not expected to serve the same or as many functions for parents. Parents are children's first teachers and socialize them to guidelines and expectations within and outside the family. Parents encourage children to develop appropriate and timely behaviors through reinforcement and modeling. Parents' ability and success in such roles depends largely on the quality of early relationship established with their child. In other words, parent-child relationships with positive qualities (such as feelings of closeness and support) tend to promote more effective developmental success, whereas those with negative qualities (such as conflict and alienation) are linked with more problematic growth in multiple child outcome domains. A child's development in the context of a positive parent-child relationship is linked with more optimal outcomes in the areas of behavioral and emotional development, relationships with siblings and friends, and academic achievement.

The foundations for enduring parent-child relationships are generally set in motion by infancy attachment. Attachment refers to the close, enduring emotional bond between parents and children. As attachment figures, parents serve as a secure base for children, providing a sense of security that encourages safe exploration of environments and safety and reassurance in times of stress. The laboratory-based test developed by leading attachment researcher Mary Ainsworth to assess this security is known as the Strange Situation. In a series of separation and reunion paradigms, observations are made of how young children respond to and interact with their primary caregivers (usually their mothers). Most children demonstrate behavior consistent with a secure attachment and positive relational qualities; they seek and obtain safety

and comfort when reunited with their caregiver after stress and separation. Children who demonstrate an Insecure/Resistant (also known as Ambivalent) attachment respond to their caregiver's return in a clingy manner. They may initially seek a connection with their mother after the separation, but are not soothed or comforted by it. Children who demonstrate an Insecure/Avoidant attachment style seem indifferent toward their caregiver upon being reunited. These children tend to ignore their caregivers following the stressful situation. Children who display a Disorganized or Disoriented attachment style show no clear or consistent way of interacting with their caregiver when reunited following a separation. These children may want to approach their mother but also seem fearful of doing so. Children with a Disorganized or Disoriented attachment style show contradictory expressions, such as smiling then freezing. Research indicates that how children fare during the Strange Situation tends to correlate with their attachment behavior at home.

Extending these descriptions of attachment styles, children's earliest relationships with their parents also depend on parental sensitivity and responding. Parents who are able to accurately identify their child's needs and provide them in a loving way establish close connections with their child. These connections have been shown to predict how children function within the family, how their peer relationships develop, and their feelings about self across the life span. Similarly, parenting qualities tend to be consistent across childhood; that is, sensitivity and responsiveness during infancy is linked with parental effectiveness later in childhood, which continues to affect how children think of themselves and what they expect of other interpersonal relationships within and outside of the family.

As young children move beyond infancy and grow into more active and independent family members, parental behavior takes on an increasing role of control or authority. Accounting for parent-child relationships in terms of the two essentially separate dimensions of responsiveness (or warmth and support) and demandingness (or control and structure), Diana Baumrind described four resulting parenting styles. First, an *authoritarian* parent is low on warmth and high on control, resulting in a harsh and demanding style.

This type of parent lays out rules or punishments without explaining why. Second, a *permissive* or indulgent parent is high on warmth and low on structure. This type of parent responds to his or her child's emotional needs, but does not set limits that help children develop appropriate regulation and control. Third, an *authoritative* parent is high on both warmth and structure. Thus, this type of parent sets appropriate limits and controls and explains why. Authoritative parents also demonstrate affection and respect toward their child, allowing the child freedom to act within appropriate limits, thereby developing a sense of autonomy and independence over time. Fourth, *neglectful* or rejecting parents (also known as uninvolved) are low on both warmth and control. They do not monitor children's behavior or respond emotionally, often remaining more focused on their personal needs rather than on those of their child. These parenting styles set the emotional tone for children in the family and relate to many domains of child development. Children of parents who are high on both control and warmth (consistent with an authoritative style) generally have higher levels of academic and social outcomes compared with children of parents with other parenting styles.

Mothers and fathers may experience differences in parent-child relationships. As examples, mothers tend to spend more overall time with their children, but fathers tend to spend more time playing with children than mothers do. Overall, fathers interact with children of all ages less than mothers do. However, new research suggests that mothers' behavior may encourage or inhibit fathers' involvement with their child: Fathers with partners who engaged in low levels of criticism and high levels of encouragement were rated as relatively more competent and involved in child-care activities.

Sibling Relationships

Although not all children develop alongside siblings, most U.S. families have more than one child. Children who are raised with and without siblings generally do not differ on a whole range of development outcomes, including behavior and emotional adjustment, peer relationships, and academic

functioning. However, for children raised in the context of brothers and/or sisters, these sibling connections are a particularly important type of family relationship.

Siblings contribute both positive and negative influences during childhood. Brothers and sisters serve as important sources of companionship, learning, and cooperation, on the one hand, and conflict and competition for resources, on the other hand. Siblings affect child development directly (through their roles of teacher or playmate) and indirectly (through effects they have on parents). Younger children may benefit from having siblings to engage with during play and fantasy and to model behaviors and conversations. Children may benefit from growing up with siblings who are more similar to peers than parents are, thus providing early examples of friendship. Having close emotional connections with siblings offers opportunities for children to learn how to manage negative feelings and to foster mutual attachments. Although sibling relationships consist of both positive and negative feelings, they tend to improve with time. As would be expected, the quality of sibling relationships tends to covary with the quality of the parents' marital relationship and parent-child relationships.

Discordant sibling relationships are more likely to occur if siblings experience differential treatment from parents. That is, the extent to which parents treat children in unequal ways has been linked with higher levels of sibling rivalry, jealousy, and conflict. In addition, families in which parents demonstrate higher levels of negative and unresolved conflict tend to contain more disrupted sibling relationships.

Even though siblings share the same status as children in a given family, they may experience different developmental contexts. First, each child has a unique family experience. This may stem from either parental treatment or birth order. Firstborn children receive more time alone with their parents. Oldest-child status may foster a greater sense of responsibility that comes from caring for younger siblings. Oldest children typically rely more on parents for developmental needs, whereas younger children learn to rely on both parents and other siblings. Younger children, however, tend to be more socially extraverted compared with older children.

Relationships Between Children and Grandparents or Other Extended Family Members

Although relatively understudied, many children's family relationships include close connections with grandparents and other extended family members such as aunts, uncles, and cousins. Extended family-member relationships may replicate the role of parental relationships in socializing children. Relationships with extended family members may fill in for relationships that children lack. For example, an only child may develop relationships with cousins that serve similar roles to sibling relationships, including providing sources of learning, companionship, and cooperation, on the one hand, and conflict or competing interests, on the other hand.

Future Directions

Family scientists continue to highlight the contributions of family relationships to childhood by designing increasingly complex research studies. These investigations typically include multiple family members and relationships. In addition, by conducting longitudinal studies, or those that capture family dynamics over time, family scientists are able to identify how relationships are linked to children's development across the life span. Although these types of research designs are time consuming and expensive, they provide rich sources of information about how children develop in the context of family relationships. Individuals in families and the relationships among them should be examined together for obtaining the clearest view of family dynamics and family functioning.

Family scientists continue to expand investigation of the diverse contexts that encompass family relationships. As examples, families' cultural backgrounds and connections have been linked to many of the relational qualities described earlier, with different cultures varying in how much they emphasize closeness among family members or express conflict. A recent study comparing Argentine, Italian, and U.S. mothers found that Italian mothers were more sensitive toward their child and optimally structuring of their child's activities, and Italian children were more involving and responsive

than occurred with mother–child dyads from Argentina and the United States. Such findings may reflect differential importance placed on individualism, social responsiveness, and warmth by societies and cultures. In addition, families' economic stress and pressures may increase conflict and tension between family members, thereby impairing the quality of family relationships in childhood. Socioeconomic status is related to family socialization processes, including marital quality, parental emotional distress, and parenting behaviors, and with child health and well-being. Studying multiple contextual influences on families sheds light on variations on family relationships and their links to childhood development.

Family studies are increasingly including genetic components to account for family members' shared environments and shared heredity. Research has indicated genetic influences on factors such as how children express social and physical aggression and on how marital discord affects child behavior problems. Thus, behaviors of family members and relationships among family members draw from both nature and nurture influences. By including both components in family studies, researchers can delineate further the sources of influence in childhood and across the life span.

Researchers' scope of families continues to broaden as children are raised in more diverse types of families. For example, more children in the United States now are raised in blended families that combine multiple primary families following parental divorce or death and in single-parent households. In addition, children tend to experience more transitions into different family structures. Thus, children now have a higher likelihood of being members of multiple family systems during their childhood and thereby experiencing multiple instances of these central family connections, including sibling or parent–child relationships. Finally, the trend of children being born to older parents might change the impact of relationships with extended family members. For example, future research will need to explore whether children have less opportunity and time to develop relationships with grandparents when born to later-age first-time parents and how this relates to their longer term development within and outside the family.

FAMILY RELATIONSHIPS IN LATE ADULTHOOD

Changing demographics and societal beliefs offer new opportunities for maintaining and expanding family relationships in late adulthood. Early definitions of aging families focused on relations between husbands and wives, parents and children, and, to a lesser extent, grandparents and grandchildren and siblings. With the aging of the baby-boom generation, a shift occurred in describing the variety and complexity of family connections in the second half of life, generating a more multifaceted view of family relationships. In 1997, Victoria Bedford and Rosemary Blieszner defined aging families to include relationships determined by biology, adoption, marriage, and social designation, and existing even in the absence of contact or emotional involvement, and in some cases, even after the death of certain members. This entry focuses on the structure, dynamics, and salience of family relationships in late life.

Demographic and Societal Shifts Shaping Aging Families

More persons are living to older ages than ever before because of advances in medical care and technology, improvements in nutrition and sanitation, and decreases in infectious disease. Thus, many older adults will be members of three-, four-, and even five-generation families. This means that family members have the opportunity to experience a variety of roles and relationships for a longer time than ever before. For example, more than 60 percent of all older adults are married and approximately 90 percent have living children; of those with adult children, about

94 percent have grandchildren and 60 percent have great-grandchildren. These percentages vary according to age, gender, race, and ethnicity.

Because of increases in the number of years people live and declines in the number of births per year, a change is occurring in the age structure of the population. Through most of the 19th century, the shape of the population structure by age in most industrialized nations, including the United States, was that of a pyramid, with a large base of children tapering to a small group of persons aged 65 and older. Families typically had many small children, fewer middle-aged adults, and no or only one or two older members. By 1990, the age pyramid began shifting to more of a rectangular shape, reflecting "beanpole" families with more generations alive concurrently within families, but with fewer children, grandchildren, great-grandchildren, siblings, and other extended kin in each generation than in previous times. By 2030, the population age structure will be rectangular, with similar numbers across all ages from bottom (young children) to top (older adults).

The progression from pyramid families to beanpole families has important implications for family functions and relationships in late life. The increased life span of older family members in recent decades results in more years of shared lives across generations. That is, although the number of kin within families is declining, the likelihood that families have members from multiple generations is increasing. For example, less than one-fourth of persons born in 1900 had a living grandparent when they turned 30; for individuals born in 2000, more than three-fourths will have at least one living grandparent with whom to celebrate their 30th birthday. Thus, the availability of aging members brings greater opportunity for greater family continuity, stability, and support across generations. At the same time, younger family members may face extended years of caregiving for dependent older adults.

There also is increasing diversity in the composition of aging families. Divorce, remarriage, long-term cohabitation, childlessness, single parenthood, nonmarital childbearing, and gay and lesbian marriage and parenthood are prominent features in the contemporary families of older adults. In addition, older adults interact with and rely on persons not related to them by birth or marriage, but whom

they converted or upgraded to kin-like relationships. For example, an older person may view a neighbor as being “like a daughter” when describing a relationship that is important and supportive. Because families play a key role in providing help and emotional support, as well as long-term care to their older members, it is uncertain how these changes in family structures will influence interactions and support patterns. For example, will adult children feel an obligation to care for both biological and stepparents? Will persons who choose not to have children be at risk of having fewer family resources? Will society acknowledge and accept family-like relationships as important sources of support and caregivers for elders?

Family Dynamics and Support

Family members provide one another with information, help with personal tasks, and emotional support. The type, frequency, and amount of support provided or received vary depending on individual needs and abilities, the type of relationship, and personal resources. Social and cultural norms or beliefs also strongly influence the extent and type of support and care provided by family members. In contrast with the majority White U.S. culture, which emphasizes democracy and individuality, the needs and well-being of the family unit are of utmost importance and a driving influence in the lives of many minority families in late life.

Social exchange theorists assert that people constantly evaluate their relationships, based on the comparability of the support exchanged. In mutually dependent relationships, such as those between family members, the costs (e.g., time, money) and rewards (e.g., personal satisfaction, companionship) occur in the context of reciprocal exchanges that take place over the course of the relationship. That is, reciprocity, when defined by familial norms, is a generalized process that does not require that exchanges occur at the same point in time and does not necessarily involve giving and receiving the same things. For example, family members in the middle stages of life tend to be the net givers of support; they provide more types of support to younger and older generations than they themselves receive. Families most often view this give-and-take of assistance and support across

generations and time as normative or routine practice rather than as a special or burdensome response to family members’ needs.

Receiving emotional support and assistance from family members often promotes and enhances older family members’ positive feelings about themselves. Emotional support, more so than actual help, acts as a buffer against the negative effects of stressful situations such as failing health or relationship disruptions. This may be because of the general societal belief that family members should provide tangible help to each other in times of need. Thus, whereas older adults expect assistance from their children and grandchildren, they value equally and perhaps benefit even more from the emotional support they receive from these relationships.

For older adults experiencing chronic health problems, having meaningful family relationships helps minimize symptoms of depression and promotes greater well-being and life satisfaction. However, not all relationships result in positive outcomes. Older adults’ desire for independence may color the intent of the help and support provided by family members, thereby increasing their feelings of distress and unhappiness. When older adults receive help that is undesired or perceived as excessive, it reinforces feelings of vulnerability, dependence, and incompetence. If they view their family members as overbearing, older adults use a variety of strategies to reduce the frequency of negative interactions. Such strategies include embracing family members’ assistance with gratitude, enabling a peaceful relationship that supports their ability to care for themselves; accepting their help with mixed emotions that occasionally generate tension, potentially compromising their ability to manage their daily lives; or refusing family member help and concealing their health problems or concerns. Thus, older adults’ response to the assistance provided (or lack thereof) depends on a variety of individual factors including their beliefs about the need for help and how they interpret the help provided by their family members.

Couples

For older couples, spouses or partners are often the primary source of daily help and support. When either person experiences the onset of a disabling health condition, it transforms the life

patterns and roles of both individuals. The way in which older persons and their partners relate to one another and the degree to which they adjust to health-related changes have considerable influence on their relationship and overall well-being. Most late-life couples are satisfied with the help and emotional support they receive from one another. However, when they receive more assistance from their partners than perceived as necessary, seemingly helpful behaviors may actually result in less satisfying relationships.

Parents and Adult Children

Although older parents often wish that their children lived nearby, it frequently is not possible. Although geographic distance may limit face-to-face contact, it does not influence the quality of the parent-child relationship in late life. Regardless of where they live, older parents typically have at least weekly contact with at least one of their adult children and view their relationships with their children as positive. Older parents hesitate to differentiate their feelings for their children, although they may favor some children over others in feelings of closeness and exchange of help and emotional support. As is true for many relationships, parents have higher levels of closeness and lower levels of conflict with adult children to whom they are more similar. The mother-daughter bond is the strongest and most enduring filial connection. Perhaps this is because older mothers believe that their daughters are more sensitive to their feelings and concerns than are their sons.

Older parents express a desire for affection, thoughtfulness, and communication from their adult children more than they want their children to provide direct care for them. Both aging parents and adult children frequently report a mutual exchange of help with tasks, financial assistance, and emotional support and assess their interactions as positive. Some parents, however, report tensions and ambivalence in their relationships with their children, with feelings of exclusion, discrepancies in perceived need for assistance, and undesirable personal attributes contributing to both overt and suppressed conflict between older parents and their adult children.

Individual and family circumstances and history influence patterns and expectations for assistance

to and from aging parents. For example, young-old parents (i.e., persons aged 65 to 74) and those with no or minor health problems often provide routine assistance to their adult children. In addition, financial assistance more commonly flows from aging parents to adult children than in the reverse direction. Adult children who are financially insecure are more likely to receive support from their older parents and to receive more of it than are siblings with fewer financial needs. Those children who return home to coreside with their aging parents usually do so because of a change in their marital, employment, or health status. These are often less than reciprocal relationships, with adult children benefiting greatly from the support of their parents. In some families, parents never stop providing direct care and oversight for their children. For examples, parents of children with developmental disabilities and mental illness frequently are lifelong caregivers.

Grandparents and Grandchildren

Although older adults consider relationships with grandchildren to be meaningful, grandchildren are often peripheral to their everyday lives. Grandparents' direct involvement with their grandchildren depends on the interplay of multiple variables such as geographic distance from grandchildren, grandparents' health, and the quality of the relationships between the grandparent and parent generations. In general, the power of parents to facilitate cross-generational relationships remains strong throughout the family life cycle. Additionally, almost one-half of grandparents will become great-grandparents; little is known about the function and meaning of this relationship whose members are potentially separated by more than a half century.

Siblings

Sibling ties in later life represent perhaps the longest kin relationship, one built on a shared family history that provides a basis for mutual emotional support and understanding. Gender, marital status, number and proximity of siblings, and family structure encourage as well as constrain interactions between siblings' relationships in later life. Ties between older sisters appear stronger than do

ties between brothers or sisters and brothers. For older men, having a sister increases the likelihood of contact and support among siblings. Having multiple siblings allows for selectivity and discretion concerning contact and frequency of interaction with any one sibling. Siblings typically provide more emotional support than physical help in late life, frequently serving as confidants and companions for one another. Brothers and sisters value their relationships with one another and typically assess their interactions as positive. However, some siblings also report conflict in their relationships, as earlier rivalries and hostilities often endure into late life.

Family Caregiving

When older persons' need for personal assistance and emotional support is required for their daily well-being, caregiving emerges as a distinct type of family support. Nearly three-fourths of older adults who need assistance with daily activities rely exclusively on family members for care. Housekeeping, meal preparation, and shopping are common caregiving tasks, and more than one-half of family caregivers regularly help their older members with feeding, bathing, dressing, and using the toilet. Older adults' preference for family care follows a predictable pattern known as the "hierarchical compensatory" model of care. Spouses are most preferred and most likely to provide care, but if unavailable because of disability or death, help from adult children is accepted, with daughters more likely than sons to take on the duties. Alliances and bonds among family members also often influence the likelihood that a particular person will provide care for another. Older adults typically adjust their expectations for care to reflect the specific realities of their family members' lives, whereas adult children must balance the needs of their dependent elders with those of their entire family. For example, more than one-half of caregivers have children living at home and juggle work with caregiving responsibilities to meet both their immediate family's financial obligations and the costs of caring for their aging parents.

Although caring for a spouse or parent is increasingly common practice in older families, a

family care situation receiving increased attention recently is that of grandparents assuming full-time parenting responsibilities for their grandchildren. Approximately 2.4 million grandparents have primary responsibility for their grandchildren. These custodial grandparents assume the care of their grandchildren for a variety of reasons including parental illness, divorce, incarceration, and substance abuse. Although older families representing all race and ethnic groups are raising grandchildren, minority grandparents are two to three times as likely as are their White counterparts to assume parenting roles. Regardless of race, ethnicity, or social class, though, few grandparents plan, anticipate, or are prepared for a second parenthood. When they assume responsibility for raising their grandchildren, they often confront several personal and social challenges as they make adjustments in their daily lives to accommodate their acquired parental roles. Many grandparents feel as if they have to manage their situation alone and report feeling judged, criticized, and abandoned by their family, friends, and community.

Regardless of which generation is providing care, there are differences in burden according to race and ethnic identification, with White caregivers typically reporting feeling greater burden than do caregivers in minority families. Differences in the level of perceived burden may be a result of stronger feelings of family obligation and greater acceptance of the caregiving situation often found in minority families. Conversely, members of race and ethnic minority groups may be experiencing similar levels of burden as that of their White counterparts, but may be less likely to express or admit to feelings of burden and stress.

Family dynamics also shape the caregiving experience for late-life families. Family caregivers of all ages often report feeling as though they have no time for themselves or others. Isolation and feelings of loneliness may result from a loss of social contacts or, perhaps more devastating, the loss of normative roles and relationships (e.g., husband-wife; parent-child; grandparent-grandchild). Although there is a tendency to focus on the negative outcomes of caregiving, family members acknowledge the positive benefits of the caregiving experience, including personal growth (e.g., gaining medical knowledge and health care skills), appreciating the elder's contributions to the

world, feeling that one is repaying an elder for care provided during earlier times in life, and more satisfying relationships.

FAMILY RELATIONSHIPS IN MIDDLE ADULTHOOD

Family life for a midlife person is busy time, with significant changes and role transitions. Generally regarded as encompassing the years between 40 and 60, people during midlife typically experience significant changes in their family relationships, including caring for their parents and grieving their deaths, launching their young adult children, maintaining marriage/couple relationships, and becoming grandparents. In this entry, middle adulthood is defined, and then family relationships during this time are outlined, including relationships with children, grandchildren, partners, siblings, and parents.

Middle Adulthood Defined

A brief demographic portrait of midlife adults using U.S. Census data indicates that most are married and have children. Racial diversity exists, however, in marital status. Although 79 percent of Caucasian men and 74 percent of Caucasian women between the ages of 45 and 54 are married, only 62 percent and 51 percent of African-American men and women, respectively, are married. African-American midlife adults are more likely than are Caucasians to be either never married or divorced. Seventy-eight percent of midlife adults have at least two children, with 13 percent having five or more. A national study of midlife found that 70 percent of those married were in their first marriage, and 30 percent were remarried. In addition, 5 percent of the never-married, divorced, or widowed midlife adults were cohabiting.

Midlife is a demanding period of time for most adults. The number of significant roles a person occupies is related to increased role conflict, role strain, and overall stress. Adults accumulate roles in early adulthood, reaching a peak in midlife. Adult child, partnership, parenting, grandparenting, occupational, and community roles converge to create substantial strain in the lives of midlife adults. The time demands of midlife were highlighted in a recent national study of midlife couples. These couples, aged 40 to 50 years, were

asked what they would change in their marriage relationship if they could change one thing. The most common theme was a wish that they could spend more time with their spouses. Twice as many responses addressed this theme rather than others such as children, sex, and money. Thus, many couples value their relationships and enjoy spending time together, yet the busy nature of their lives may interfere with couple time.

Relationships With Children

Midlife parent relationships with children are diverse. Although some parents have small children during this time, many have adolescent and emerging adult children. In addition, many middle adulthood parents have foster, adoptive, and stepchild relationships.

Parent-child relationships can be somewhat strained during middle adulthood because both parents and children are negotiating different levels of control, support, autonomy, independence, and responsibility. Regarding these goals, research has indicated that the well-being of parents in middle adulthood is related to the assessments they make of their children's accomplishments. Teenage and young adult children who mature, complete their education, gain experience with work and romantic relationships, and prepare to leave the home contribute positively to parental well-being. As children launch from the home, most parents experience a successful transition. In addition, parent-child relationships typically improve after children leave home.

Relationships With Grandchildren

Many parents transition into the grandparent role during middle adulthood. Although grandparents take different styles and approaches to interacting with their grandchildren, most are satisfied with these relationships. Often, the approach grandparents take is linked to the meaning that they derive from the relationship. For many, grandparenting is a formal experience, with occasional interactions, some indulgence, and little discipline. Others prefer a fun-seeking approach, engaging in the relationship with playfulness. Grandparents can become involved in their grandchildren's lives

to the extent that they provide daily care and discipline. This is especially so among African-American and Hispanic households. About 6 percent of grandparents provide custodial care of their grandchildren, and this phenomenon is growing. Even though the stress of custodial grandparenting is associated with physical and emotional strain, grandparents find satisfaction in this role and report they would take in their grandchildren again if needed.

Several additional factors influence grandparenting in middle adulthood. Grandparents in middle adulthood have more visits and phone contact with grandchildren than older grandparents have. Middle-aged grandparents, however, also report that their relationships with grandchildren are more tiring. This is likely because they have younger grandchildren who require more physical supervision. The salience of grandparent-grandchild relationships is most strongly influenced by the relationship of the grandparent with her or his child (the grandchild's parent). When these relationships are strong, grandparent-grandchild relations also tend to be strong. Grandparent-grandchild relationships also tend to be stronger when the middle-generation link between the grandparent and the grandchild is female. Proximity, or the distance between grandparent and grandchild residences, influences the amount of contact grandparents have with grandchildren and the degree of involvement they experience in each others' lives. Lastly, ethnicity plays an important role in grandparent-grandchild relationships. Specifically, African-American grandparents often play a more integral role in the lives of their grandchildren than do Caucasian grandparents, many times providing direct care for the grandchild. Hispanic grandparents are also typically involved to a greater degree than are Caucasian grandparents and sometimes live in multigenerational households. In summary, grandparents in middle adulthood often have an active and satisfying relationship with their grandchildren.

Relationships With Partners

Although couple relationships in middle adulthood are quite diverse, romantic relationships at this stage are most commonly found in the form

of marriage. In a life-course context, marital satisfaction generally declines slightly with time, yet may improve in the later years. Research suggests that this early decline may be because of the presence of children (resulting in increased workload and less time together) and role demands associated with family, work, and community. As midlife couples move into their later years, they generally have fewer role demands associated with parenting, which allows for more time together as a couple. In addition, research by Laura Carstensen suggests that couples experience fewer negative interactions and more positive ones in their relationship as they get older.

Midlife often introduces physical challenges and health concerns to the marital relationship. Common age-related health problems such as Type II diabetes, cardiovascular problems, and arthritis may require adjustment in marriage. Some health changes related to intimacy also occur during middle adulthood. The most common of these is menopause, where hormonal changes in women can influence mood, physical comfort, and sexual functioning. Conversely, intimacy among postmenopausal women and their partners may improve as worries about pregnancy are no longer an issue. For men, cardiovascular functioning can also lead to changes in intimacy, such as with erectile dysfunction. Available medications and hormone replacement therapies can sometimes assist with the health changes women and men experience in middle adulthood.

Divorce

Divorce is most common among couples during the early years of adulthood, but it also affects a number of midlife couples. In the United States, 27 percent of divorces in a given year involve men between the ages of 45 and 64, while 18 percent of divorces involve women between the same ages. In contrast, 71 percent of men and 80 percent of women experiencing a divorce are under the age of 45. Only 2 percent of divorces involve either men or women older than 65 years. The probability of future divorce is 23 percent among 40-year-old men, 8 percent among 50 year olds, and 2 percent among 60 year olds. Among women, the probability decreases from 18 percent at age 40, to 6 percent at age 50 to 2 percent at age 60.

However, the divorce rate in midlife is increasing. The divorce rate among 45 to 49 year olds has doubled since 1971, and it has tripled among those aged 50 to 54. Predictors of mid- and later-life divorce include higher education, discrepancy in spouses' marital history, being in a second marriage, older ages of children, and having a small number of siblings. A recent national study of people who divorced after age 40 found that women initiate the divorce most of the time. The most frequent reasons for divorce among women were, in order, verbal, physical, and emotional abuse; different values and lifestyles; infidelity; and alcohol or drug abuse. For men, the most common reasons were falling out of love; different values and lifestyles; verbal, physical, and emotional abuse; and infidelity.

Marital dissolution generally has negative economic and psychological consequences. One study found that divorced men between the ages of 50 and 73 who had been married at least 15 years experienced a 61 percent decline in income, while women suffered a 66 percent decline. Thirty-five percent of the women and 21 percent of the men in a national study of midlife divorce reported suffering significant symptoms of depression following the divorce, with 31 percent of the women and 18 percent of the men having been diagnosed with depression by a physician.

Evidence suggests that people divorcing in midlife have an easier adjustment than do those who divorce earlier in adulthood. Women divorcing after age 40 are less likely than younger women to suffer from depression and feelings of hostility. Among those who have been divorced at least twice, 53 percent of the men and 42 percent of the women in one study reported that their first divorce, when they were younger, was more difficult, usually because of the emotional and legal complexities of having younger children.

Divorce in mid- and later life affects intergenerational relationships, especially among midlife fathers. Research has consistently found that divorced midlife men experience deteriorated relationships with their adult children. They have substantially less contact with their children, and adult children report significantly worse relationships with their fathers after their parents' divorce in later life. One study found that adult children whose parents are divorced are 33 percent more

likely than are adult children of married parents to have a detached relationship with their father. In summary, divorce affects family relationships in middle adulthood in numerous ways.

Relationships With Siblings

Sibling relationships are often the longest family relationships a person experiences. In some ways, sibling relationships in middle adulthood may be characterized by patterns established earlier in life, such as extent of competition or playfulness. In other ways, life changes influence patterns of sibling interaction and emotional closeness.

Competition among siblings often continues into middle adulthood. This competition may play out in vocational success, closeness to parents, and accomplishments of their children. At the same time, previous conflicts among siblings have often been overcome by the time siblings reach middle adulthood.

The frequency of contact between siblings in middle adulthood follows a different trajectory to the emotional connections siblings share. Some have suggested that contact between siblings across the life course follows an hourglass shape, with the most frequent contact in childhood and later life and less interaction during middle adulthood. The distance in middle adulthood is often caused by role demands of having spouses, children, work demands, community involvement, and so forth. When role demands decrease, such as with launching children, retirement, and divorce or widowhood, sibling interactions often increase. Caring for aging parents also often encourages siblings to interact more frequently than before and to work together for a common cause. Although sibling interaction and contact may decrease in middle adulthood because of these role demands, sibling relationships, in general, remain emotionally close, and may even become closer with time. Closeness in sibling relationships is influenced in middle adulthood by transitions such as divorce and (re)marriage, launching children, retirement, caring for aging parents, and the death of parents. Sibling relationships are sometimes close as a result of being encouraged by parents. When this is the case, after aging parents die, sibling relationships tend to dissipate. In addition, sibling relationships

among sisters are typically stronger than among brother pairs or brother-sister pairs. In summary, sibling relationships in middle adulthood consist of less interaction than at other times in life, yet emotional closeness often remains stable or increases.

Relationships With Parents

Middle adulthood is a time of both stability and change in relationships between adult children and their aging parents. Regarding stability during this stage of life, adult children and their parents can potentially enjoy mature, positive, and companionable relationships. Regarding change, it is common for midlife adults to assume the responsibility of providing care for a disabled parent. In many cases, the older parent's spouse is the primary caregiver, with middle-aged children serving as secondary caregivers. Although they may not provide day-to-day personal care, they help with transportation, perform household upkeep and repairs, and provide respite for the primary caregiver. In families where the older parent is single or the spouse is physically unable to provide care, adult children generally assume primary caregiving responsibilities.

Caregiving

A recent national survey of primary caregivers indicated that 68 percent of child caregivers were between the ages of 45 and 65 and an additional 14 percent were over the age of 65. Slightly more than half of them reported coresiding with their parent. They typically cared for their disabled parent 7 days a week, averaging 25 hours of primary care each week.

Providing care for parents is stressful. Research comparing caregiver children with similar midlife adults who do not have caregiving responsibilities indicates that caregivers are more likely to suffer from depressive symptoms and experience health problems. Although stressful, most adult children report deep satisfaction in their caregiver role. An exception occurs if the relationship between the parents and the child is strained; in these instances, the caregiving obligations may create resentment. Caregiving also often creates stress with work

situations. In one study, more than half the adult child caregivers reported that their jobs had been negatively affected by their caregiving responsibilities, with nearly one-fourth of them taking time off from work without pay to care for their parent.

Bereavement of Parents' Death

Midlife is the most common stage in which a person's parents die. Ninety-five percent of 40-year-old adults have at least one living parent, while only 25 percent of 62 year olds have a living parent, suggesting that parental loss is most commonly a midlife experience. This can be one of the most stressful, traumatic events in a person's life, with surviving children of deceased parents experiencing symptoms of grief, including depression and physical ailments. Moderators resulting in less intense and complicated grief include having a positive relationship with the deceased parent, being married, being religious, anticipating the death, and providing extensive care for the parent before death. The last moderator is due to the buffering effects of being relieved of demanding caregiving responsibilities. Having an ambiguous, hostile, or distant relationship with a parent leads to a more complicated grieving process.

Published research suggests that the death of a parent of an adult in midlife can have a negative impact on the quality of the midlife couple's relationship. In a cross-sectional study, after the death of a mother, 20 percent of the midlife respondents reported an increase in conflict with their spouse. The death of a father resulted in 29 percent of the adult children reporting increased conflict with their partner. More specifically, 11 percent of the couples reported that the death of a parent contributed directly to their decision to divorce or separate. The most common reason cited was that they no longer felt the need to remain together because of parental expectations. Many respondents also stated that their significant other was unable to understand the depth of their grief or provide the needed support during this difficult time. In 1995, Debra Umberson's analysis of longitudinal data confirmed the impact of parental death on midlife marital quality over time, showing that marital relationship quality declined when either a father or a mother died. Analysis of the open-ended interview data suggested that the

relationship stress was largely the result of the unbalanced nature of the grieving process. Typically, only one partner went through an intense grieving process, which put the partners in different emotional states. The relationship stress, though, was usually temporary because the relationship regained emotional balance as the intensity of the grieving process diminished.

FAMILY RELATIONSHIPS IN YOUNG ADULTHOOD

Early adulthood is marked by exploration and experimentation in new roles, and frequent, fast-paced, life-course changes. Most young adults have not “settled down,” but experience frequent changes in life circumstances, including home-leaving, moving into and out of romantic relationships, jobs, and educational settings.

Consistent with Glen Elder’s notion of the dual dynamic of individual and family change—the simultaneous and mutual influence of family members’ individual developmental paths and change in the family system—research has made clear that offspring’s individual development and family relationships are mutually influencing during early adulthood. Moving into adult roles reshapes sons’ and daughters’ network of family relations. At the same time, family relationships may support or impede young adult development and transitions. This entry describes the family relationships of young adults, ages 18 to 25. The review focuses on relations with parents, on which the bulk of research has been done. Relations with siblings and grandparents are also discussed.

Changing Relationship With Parents

In early adulthood, the parent–child bond evolves toward a relationship between two adults rather than between adult and child. This is marked by a growing ability of youth to express differences and separateness while remaining emotionally close to parents. Nonetheless, parent and young adult offspring have not become equals in the relationship. Jeffrey Arnett’s research with U.S. youth suggests that most young people in their late teens and early twenties will not think of

themselves as fully adult, but as between childhood and adulthood. Goals for youth during this phase include increasing their independence from parents, taking responsibility for their own decisions, and becoming financially self-sufficient. At the same time, most young adults need both emotional and material support from parents to thrive. Research in this area has focused on U.S. and Western European youth. Its applicability to developing and non-Western countries has not been determined.

The interplay between young adults’ needs for both autonomy and continued dependency on parents may be one of the strongest forces reshaping family relationships during this phase. The tasks that face both young adults and their parents often involve reconciling contradictory impulses. Parents need to acknowledge the adult status of their sons and daughters, relinquish control, and, at the same time, remain ready to provide the care and material support their offspring need to thrive. Young adults need to pursue independence from the family of origin while still relying on support from parents or other kin to enhance their ability to explore new roles. Parents and offspring need to negotiate their expectations about family obligations as young adults move toward financial and residential independence and establish their own families and households.

Maturity for young adults also means coming to understand their parents as individuals in their own right. Referred to as *filial maturity*, this involves adult children’s growing ability to understand their mother and father apart from their parent roles, to appreciate a parent’s unique life history, and to develop a deeper understanding of a parent’s needs, desires, and worldview. Filial maturity implies becoming dependable to parents (rather than dependent on them) and is a precursor to becoming a source of support for parents in later life. Children’s felt obligation to support parents grows stronger in early adulthood and is linked to increased reciprocity in parent–child exchanges of support.

Continuity in Parent–Child Relationships

Social Learning Theory and Attachment Theory provide a basis for expecting continuity between

earlier patterns of parent–child interaction and parent–child relationships in early adulthood. Social Learning Theory holds that patterns of interaction ingrained when children were younger will be repeated as children and parents enter a new life stage. Attachment Theory suggests that the attachment relationship with parents formed in early childhood may become a stable aspect of personality influencing later styles of interaction. Empirical evidence for these theoretical notions is mixed. Data from longitudinal studies have shown modest levels of continuity over time but a substantial capacity for change. Research by Jay Belsky that followed children from age 3 to age 26 in New Zealand found that interaction patterns from early and middle childhood were unrelated to relations between parents and their 20-something offspring. There was some evidence of continuity from adolescence into early adulthood, with parent–adolescent relationship quality positively associated with young adults’ closeness to parents. Although significant continuity effects have been found in several other longitudinal studies, these effects tend to be modest. The New Zealand study showed that parent–adolescent interaction patterns explained less than 4 percent of the variance in parent–young adult relationships when measured from the young adult’s perspective. William Aquilino’s longitudinal research using the National Survey of Families and Households showed slightly larger continuity effects from adolescence into early adulthood when relationship quality was measured from the parents’ perspective. Parent–adolescent conflict predicted higher levels of parent–adult child conflict and accounted for about 10 percent of the variance in adult conflict.

The moderate influence of past interaction patterns suggests that grown daughters and sons can establish relationships with parents that are qualitatively different from those of earlier stages. The changing life course of parents and children provides the impetus for a reappraisal and renegotiation of the parent–adult child relationship. Children’s transitions into adult roles furnish an opportunity for parent and offspring to forge new patterns of interaction. Home-leaving may be the most critical transition. Leaving home marks the end of direct parental supervision and daily contact with parents. This opens the door to a deeper

understanding among parents and offspring that their relationship has changed, or needs to. Home-leaving has been linked to adult children’s heightened feelings of autonomy and more warmth and less confrontation with parents. The influence of parent–adolescent relations on parent–adult child relations diminishes after children leave home.

A substantial body of research has shown that changes in family composition and custody arrangements during childhood have long-term effects on parent–child relations in early adulthood. Conflict between parents, before and after marital dissolution, results in children feeling reduced intimacy with parents in adulthood. The negative effects tend to be especially strong for adult children’s connections to the noncustodial parent, but lasting negative effects are not inevitable. When noncustodial parents maintain strong relations with their offspring after the divorce, children tend to experience less anger toward the parent and less sense of loss in early adulthood. Parental divorce that occurs after children are grown also weakens adult child–parent relations, resulting in reduced contact and intimacy, especially with fathers. Father–daughter relations appear to be more vulnerable to later-life parental divorce than any other parent–child dyad.

Emotional Bond With Parents and Young Adult Outcomes

Family relationships affect young adults’ psychological well-being, transitions to new roles, capacity for intimacy, and individuation from the family of origin. Important aspects of the emotional bond between adult child and parent include levels of involvement, warmth, support, and mutual acceptance.

In early adulthood, a parent–child relationship marked by strong attachments and emotional closeness will foster sons’ and daughters’ autonomy from the family and their ability to function independently. Research on adolescence during the past several decades has shown that continued connectedness to parents, rather than repudiation of parental ties, facilitates individuation from the family of origin and successful transitions into adult roles. Parental acceptance and support for independence lead to higher self-esteem among grown children. Parental resistance to children’s

growing autonomy slows individuation from the family and contributes to psychological distress and impaired social functioning in early adulthood. Sons' and daughters' achievement of independence proceeds best when they feel connected to parents, understood and loved in their families, and secure in being able to call upon parents for support.

Relations with parents may affect young adults' capacity for intimacy. Longitudinal studies that have tracked young people from the teenage years into early adulthood have found that parental behavior marked by warmth, support, acceptance, and involvement is associated with young adults behaving in a more supportive and less hostile manner with their romantic partners. Cohesion and a flexible style of control in the family of origin have been linked to young adults reporting more happiness in their romantic relationships. Research with never-married adults age 19–35 has shown that parental divorce can lead to difficulties in romantic relationships for young adults, more so for women than men. Women with divorced parents reported less trust and satisfaction, and more ambivalence and conflict, in their intimate relationships. For some young adults, however, the consequences of experiencing a parental divorce for their own intimate relationships can be positive. The capacity for positive effects depends on how well the adult sons and daughters come to understand their parents' divorce. Youth with a more integrated understanding of their parents' divorce, involving an awareness of the complexity of their parents' relationship and an appreciation of their mother's and father's viewpoints, report higher levels of intimacy and enjoyment in romantic relationships.

Family Economic Support and Young Adult Outcomes

Parents who provide financial support to their young adult offspring enhance their children's success in the transition to adult roles. Parents' financial backing results in increased educational attainment and higher living standards for their adult children. Parents may provide economic support in a number of ways, including paying tuition for college or other postsecondary education;

providing financial subsidies that enable young adults to live independently (e.g., paying monthly bills); allowing adult children to coreside in the parental household; paying for health and auto insurance; and providing other necessities to their grown offspring, whether they live with parents or reside independently.

Parents' capacity to offer economic support to adult children varies positively with parental income and education and is negatively related to family size. Other factors affecting the propensity for parents to make financial transfers to adult offspring include parental divorce and remarriage. Family disruption during childhood and the transition to a stepfamily weaken parental feelings of obligation to support adult children economically. Stepchildren receive less parental economic support than do children from two-biological-parent households.

Some parents have been shown to use their economic leverage to achieve more control over the behavior of young adult children, especially with regard to transitions into and out of the parental home. Parents can facilitate their son's or daughter's home-leaving by helping to pay for the child's daily living expenses, thus making it more feasible for youth to establish an independent household. When young adults live independently, parents who are unhappy with a child's lifestyle or who doubt his or her ability to make sound decisions may try to nudge the child back into the parental home by cutting off the financial subsidies that enabled independent living.

In the United States, it is common for youth in their early to mid-twenties to live in their parents' households. According to U.S. census data, 56 percent of men and 43 percent of women age 18 to 24 lived at home with one or both of their parents in 2000. One in four young adults leave home for the first time after age 22. Returning to live with parents after a period of independent living is also common. About 40 percent of youth who first leave home between ages 17 and 20 later return to live with parents. These returns are usually for a limited time, less than 2 years, while making the school-to-work transition or while changing jobs.

Adult child coresidence can be considered a form of parental economic support even though it may not involve direct cash transfers to children. Most adult children live rent-free in the parental

home, and relatively few make monthly monetary contributions to the household budget. Data from the National Survey of Families and Households showed that fewer than one quarter of coresiding young adults made room and board payments to parents.

Similar to direct financial transfers, the economic benefits of coresidence with parents may be advantageous for the prospects of sons and daughters making the transition to adulthood. Modern labor markets have increasingly favored job seekers with more education, skills, and training. Young adults can use the secure base of the parental home to gain more time and have more resources needed to prepare themselves for achieving financial independence. Money saved by residing with parents will make attending college or acquiring other postsecondary training more feasible. Without the burden of monthly bills when living independently, young adults can undertake a fuller exploration of career options in which changing jobs or switching career paths will not result in a financial crisis.

Among young adults from poor or lower socioeconomic status families, living at home, with minimal living expenses, will make attending a local college or technical school more feasible. It will be easier for young adults to combine part-time employment with postsecondary education when they are not also responsible for sustaining an independent household. Among youth not attending college, coresidence provides for their basic needs as they negotiate a difficult job market and gain experience in low-paying, entry-level jobs. Lower socioeconomic status families may also benefit from the economic contributions coresident offspring make to the household.

Research has shown that parent–adult child relations during periods of coresidence are generally good, as long as parents perceive that their offspring are making progress toward independence by furthering their education, developing new job skills, or seeking employment. Parental satisfaction with the living arrangement increases when coresiding adult children contribute to their own upkeep by paying for some or all of their own transportation, clothing, insurance, and entertainment expenses. Parental reactions to adult–child coresidence tend to be most negative when offspring appear to be floundering in making progress

toward independence, such as when youth are simultaneously not employed and not pursuing further education or training. The most difficult coresident situation for parents is when sons or daughters bring their own children into the home as well. The three-generation household thrusts parents into caring for young children, a role most had happily relinquished as their own offspring moved toward adulthood.

Naomi White's qualitative research on Australian youth who returned home revealed a number of difficult interpersonal issues that challenged both parents' and adult children's satisfaction with the return home. Both parents and children struggled with establishing emotional boundaries and often lamented the loss of privacy they previously enjoyed when living apart. Despite their dependence on parental resources, offspring wanted to be recognized by parents as independent adults. Resentment surfaced when parents attempted to set rules for overnight visitation, curfew, and contributions to housework.

Other Family Relationships: Siblings and Grandparents

There is little empirical research on sibling relationships in early adulthood. This is one of the least studied relationships in the family system. There is conflicting evidence in prior research about whether sibling relationships are important to young adults' social networks and whether sibling relationships contribute to well-being in this life stage. Although some research suggests that young adults are nearly as close to their siblings as to their parents, other evidence suggests that friends become more central to the social networks of young adults than siblings do. College students tend to share more interaction and communication with friends than with siblings. However, sibling relationships appear to strengthen with age. In middle age and later life, adults increasingly look to their siblings for support.

Observational research by Joann Shortt and John Gottman has provided insights into processes that facilitate strong sibling relations in early adulthood. To build strong bonds in adulthood, siblings need to move beyond the asymmetrical relationship characteristic of childhood sibling

relations, where age differences are critical and older siblings often dominate, and establish a more symmetrical relationship between equals. When the power differential between siblings remains an issue, similar to the power relations between children of different ages, research has shown that conflict and defensiveness are more likely to interfere with the establishment of strong bonds and open communication among siblings in early adulthood. Eliminating the power imbalances that characterized childhood interaction may be a critical task necessary for siblings to enjoy supportive relations in early adulthood.

There are also relatively few studies of young adults' relationships with grandparents. Gender and race are two factors that appear to strongly influence the nature of grandparent-grandchild relations in early adulthood. Because women often function as "kin-keepers" in the family and maintain stronger ties to their extended families than do men, it is common in the United States for children to grow up feeling closer to their maternal grandparents than to their paternal grandparents. In addition, the granddaughter-grandmother relationship tends to be the closest compared with other gender pairings. As grandchildren move into adult roles such as employment, marriage, and parenthood, their relationships with grandfathers improve.

Research suggests that grandparents can play an important role in providing support to young adult grandchildren. Most studies in this area have focused on minority youth, with particular attention to the African-American family. Among college students, African-American youth are more likely to engage in supportive exchanges with grandparents than are White students. African-American grandparents are more likely than are White grandparents to act as surrogate parents to grandchildren. To understand more fully the family resources and support available to youth during the transition to adulthood, research should include the contributions of grandparents and other extended kin. This appears to be especially important for understanding the prospects of African-American and other minority youth. Research is needed to illuminate the extent of grandparents' economic support to adult grandchildren, the impact such support may have on the early adult life course, and the factors that affect the likelihood of young adults receiving support from grandparents.

Conclusion

Frequent and fast-paced changes in the young adult life course transform family relationships, leading to new styles of interaction with parents and other family members. At the same time, family relationships shape the individual life trajectory of sons and daughters in early adulthood. The quality of relationships with parents and kin and the availability of emotional and material support from the family of origin play a critical role in young adults' achievement of autonomy and maturity. Family support bolsters the young adult's prospects for success in the transition to adult roles. The tension between the young adults' drive for autonomy and their continued dependence on family support reshapes the terrain of family relationships during this life stage.

FAMILY ROUTINES AND RITUALS

Families organize their collective lives through the structure of routines and impart what it means to belong to the group through its rituals. This entry provides a general definition of routines and rituals and charts how they change through the family life course.

Routines are behaviors or activities that involve a sequence of highly ordered steps. For instance, routines around dinnertime might include a set time and place for dinner, roles (e.g., who puts napkins on the table), and assigned seats. Routines are repeated over time with little change in sequence. *Rituals*, however, are highly symbolic and provide a sense of belonging for family members. Elements of such symbolic gatherings are anticipated and thought about long after the event concludes. For instance, the family may have a special Sunday evening meal that is anticipated by all family members. The emotion and affect accompanying such a special gathering might be the subject of stories told long after the event.

Families have a life course that involves various phases as the family develops over time. The family life cycle typically moves from being a married couple, to living with young children, parenting adolescents, and then the absence of children in the home. However, not all families follow a nuclear family structure; there might be other family members (e.g., cousins, grandparents) living with the family. Further, these life phases are not rigid because divorce, remarriage, extended family moving into the home, and even death may prompt the family to experience one or more of these phases again or concurrently. Transitions from one phase to another are often stressful, so routines and rituals can promote healthy adaptation and continuity across the life cycle. Routines and rituals provide the family with a sense of structure and meaning that allow family members to anticipate future events and look forward to them even in the midst of stressful times.

Early Marriage

During early marriage, couples choose new routines and rituals, as well as deciding which routines and rituals from their upbringings will carry forward into their life together. For many couples, this will involve agreeing on the meaning and incorporation of religious observations and rituals. Interviews from married couples suggest that there are several types of marriage rituals including couple-time rituals (hobbies, sports, movies), which often involve the couple setting time aside to be alone together (coffee on Sunday mornings). Other types of rituals may be idiosyncratic or symbolic (favorite television programs, celebrations), daily routines (household management, meals), and communication rituals (daily phone calls).

Transition to Parenthood

With the birth of a child, the couple must adapt to new routines and schedules (e.g., feeding, bathing). These new routines also provide infants the opportunity for social interaction. For instance, when a parent responds to an infant's cry for food, the parent is aiding the child in developing a sense of awareness about how its actions influence others. Feeding routines help the infant develop a wake-sleep cycle that can lead to regular sleeping routines and generally better self-regulation. When routines become stable for an infant, the infant is easier to soothe and care for. This, in turn, may ease the transition to parenthood. Cultural variations in routines are seen in many different specific behaviors, for example, the incorporation of high chairs during feeding. High chairs are especially prominent in Western cultures, whereas a Puerto Rican mother is more likely to hold the infant in her lap during feeding.

Parenting Preschool and School-Age Children

Young children practice various routines including daily routines such as mealtime and bedtime, household duties, discipline routines, and homework routines. As the child develops both cognitively and behaviorally, negotiation and problem solving occur between parent and child, allowing for more variations in routines among preschool

and early school-age children. Between the ages of 3 and 6 years, interactions within the family allow for language development through joint book reading and dinnertime conversations. Structured routines during this period also help prepare the child for routines during the school day and contribute to better behavioral adjustment. Routines allow children to reliably expect and depend on a sequence of events, which ultimately facilitates better adjustment among children. Culturally, variations in mealtime discussions are noted where U.S. families tend to focus more on daily events and are more child-centered, whereas other cultures, such as Japanese American, focus more on past events shared by the family.

Parenting Adolescents

Although adolescents seek autonomy, family routines and rituals continue to be important sources of stability for the adolescent. Adolescents may perceive routines as an indication of parental emotional investment in the family and develop a stronger sense of self from such routines. Further, the structure supplied by family routines often reduces the adolescent's feelings of anxiety and even exposure to risk-taking situations. Adolescents experience less anxiety because the familiarity of a particular routine and may also be less likely to deviate from such certainty into more risky situations. Although the time spent engaging in such routines might decrease, the meaning and importance of family rituals for the adolescent may not. For example, many religious rituals, such as bar or bat mitzvahs, serve as a means for the family to recognize simultaneously the independence of the adolescent and the adolescent's strong family connections.

Children as Older Adults

As children become adults and move out of the home, there tends to be a decrease in the practice of routines in the home. Further, with children no longer in the home, rituals tend to be centered on religious and community-linked events (e.g., holidays), rather than on those that were unique to the family. When the couple later becomes grandparents, there is often the desire to pass rituals on to the next generation.

In sum, routines aid families as they transition from one part of the life cycle to the next, create a context that is conducive to social and emotional development, and when repeated over time become part of the family's ritual life. Passed down across generations, these rituals encourage family, personal, social, and even cultural identity, which let individuals know that they belong to an important group.

FAMILY THERAPY

Families represent one of the most important contexts for human relationships. Although individuals experience many types of relationships during their lifetimes, both lay persons and experts in the field generally agree that family relationships are among the most influential and complicated. For instance, there are countless studies in developmental psychology demonstrating that the quality of key family relationships has important and long-lasting impact on the development of virtually every personality characteristic and form of psychopathology. When family relationships function well, they are one of the most satisfying experiences a person can have. However, when family relationships do not function well, they are one of the most distressing experiences a person can have. When family problems emerge, families are

increasingly turning to family therapists for help. In fact, family therapy is one of the most common forms of mental health treatment. This entry discusses how family therapy is defined, reviews existing research about the efficacy of family therapies and about family therapy process, and explores current research to further understanding of the effectiveness of family therapy.

Definition

Defining *family therapy* is a difficult task for several reasons. Family therapy is sometimes labeled by virtue of the presence of multiple family members in the therapy room, but also is at times labeled by the presence of a systemic perspective in any therapy format that emphasizes the family system in the therapeutic work. For instance, Bowen Therapy is an example of a one-person family therapy. As scientists have refined their conceptualization of family therapy, consensus has grown that what matters most is whether or not the therapy was family-based rather than who was present in the therapy room.

Further, many family therapies today are actually multicomponent treatment packages that may involve the use of medication, group sessions for a client presenting with a specific problem, sessions with family members excluding the client, individual therapy sessions for the client, psychoeducation, and therapy sessions with all family members. There is also debate about whether couple and family therapies should be grouped together because they both involve treating multiple family members at the same time. Still, some believe that couple and family therapy differ sufficiently enough to merit separating the two. For present purposes, this entry uses *family therapy* to describe therapy methods that use a systemic focus on the family.

Family Therapy Principles and Models

To understand family therapy, it is important first to understand the basic tenets that underlie family functioning. A family typically involves two to four generations. A family is influenced and facilitated by the opportunities and constraints of its social context. To ensure its own existence, a

family adapts available resources to normal and abnormal transitional and crisis stress events. Family resources involve the ability of family members to contribute tangible help such as material support, income, childcare, and household maintenance and nontangible aid such as expressive interaction, emotional support, instruction, and social training and regulation. All families have explicit and implicit rules that govern their interactions, and those rules usually promote robust patterns of interactions. How well a family functions depends on such aspects of family life as the clarity of its communication, rules, and ability to actualize family resources during a time of crisis.

A family systems perspective is central to family therapy. From this perspective, individual problems occur in the broader context of the family. Therefore, family therapy focuses primarily on interpersonal interactions rather than on intrapsychic phenomena. For instance, the goal of family therapy for depression is to change the relationship patterns between a husband and wife to mitigate depressive symptoms, the rationale being that depression can cause relationship problems and that relationship problems can cause depression. This contrasts with traditional Cognitive Behavioral Therapy for depression where the focus is on altering an *individual's* thoughts and behaviors. Moreover, family therapists have historically understood causality in family interactions through cyclical causal patterns—that is, sequences of ongoing, interactional behaviors that have no clear beginning or end.

Each family system comprises a number of subsystems, which affect one another. “Wholeness” highlights that the whole is more than the sum of its parts, with the implication that there is little point in considering one part of the family system without regard to the rest of the system. Family therapists believe that such properties of systems affect individuals within the system. In earlier views, systems, much as in the context of physics, were seen as homeostatic, that is, moving to reduce change. However, more recent views have seen the family as a source of resilience more than of homeostasis. Today's family therapists believe that families possess the ability to rally their resources to restore healthy family functioning.

Family therapists go about understanding symptomatic behavior in many different ways. Some

view symptoms as a result of the family under stress, others look for the meaning or function of the symptom, and still others view symptoms as a result of repeated use of the same flawed solution. Such different ways of understanding symptomatic behavior in one or multiple family members is closely related to the theoretical orientation of the family therapist. *Psychodynamic models* focus on the family as an integral context in the etiology of adult personality and believe that to solve family problems, it is necessary to understand intrapsychic processes within the individual, to understand early parent-child relationships, and to understand the evolution of family problems across generations. *Experiential models* focus on increasing the family's sensitivity and sharing of feelings. *Structural family therapy* focuses on patterns of interaction within the family to understand its basic structure and organization. *Strategic models* use paradoxes as a technique for changing family patterns and interactions. Therapists using *narrative* and other *postmodern models* believe that there is no objective reality; rather, people construct their realities and focus on understanding the family's shared definition of the problems. *Cognitive behavioral models* use principles from learning theory and social exchange theory to understand family processes. Each of these viewpoints has evolved into a school of family therapy.

Most recently, a movement away from specific theoretical orientations has developed in favor of identifying a set of generic strategies or principles that cut across theoretical orientation. Most family therapy today, in part, uses strategies that work with family structure; strategies that work with cognitions, narratives, or attributions; strategies based in psychoeducation; and strategies for working with affect. Hence, the field of family therapy has moved toward a both/and paradigm rather than an either/or paradigm. Current views of Systems Theory allow the therapist to examine causal processes, to examine the differential impact of family systems processes on different family members, and to examine the impact of intrapsychic processes of individual family members on the larger family system. Although systemic conceptualizations have changed over time, the ultimate goals of successful family therapy remain the same: to resolve the family's difficulties and add to adaptive functioning by rectifying a family's

dysfunctional, repetitive interactions, communication, and problem-solving skills.

Effectiveness of Family Therapies

With now about 40 years of research on the efficacy of family therapy, it is clear that family therapy is effective. Research has shown that clients in family therapy are better off than approximately 70 percent of clients not receiving treatment. Research also shows that family therapy is at least as effective as other treatment modalities, such as individual therapy. There is more evidence for the efficacy of family therapy for specific problems (e.g., conduct disorder in children and adolescents) than there is evidence that specific types of family therapy are better than any other specific type (i.e., structural vs. strategic family therapy). Family therapy has been shown to have a particularly powerful role in the treatment of adolescent substance use disorders and delinquency, schizophrenia and bipolar disorders, and eating disorders. For example, research has found that family treatments result in approximately 80 percent of adolescents being drug-free at termination and that family treatments produce twice as many drug-free adolescents at termination when compared with group therapy or family-based drug education programs. Other research has shown that family therapy focused on reducing expressed emotion, which is characterized by high levels of emotional intensity and criticism of the patient, reduces relapse and symptomatic behavior when used in conjunction with medication and skills training in the treatment of clients with schizophrenia and bipolar disorders. Rates of recidivism have been reduced by as much as 50 percent through the addition of such family treatment strategies. Both these threads of research show that with some problems, family treatment is far more cost effective than are individual therapy, hospitalization, and standard, nonfamily treatments.

Family Therapy Practice: How Family Therapy Works

What happens both inside and outside of therapy sessions that leads to desired outcomes such as

improved functioning, improved communication and relationships, and decreased symptoms? This is a topic about which research has only recently begun to emerge. One important finding is that a strong alliance between the therapist and the family is central for positive change to occur. This therapeutic alliance includes each individual family member's alliance with the therapist, as well as the family's alliance as a whole with the therapist and each family member's view of the therapist's alliance with the other family members.

Family therapists tend to take a more assertive and active role in therapy than do most individual therapists. When family members make positive changes in therapy, the changes tend to cross the dimensions of cognitive, affective, and behavioral change. The effectiveness of a family therapy session is influenced by the family's level of cooperation and family members' active participation in the problem-solving process.

Balancing the needs of multiple family members and working in the best interest of the family system can be challenging. What may be in one family member's best interest may not be in the best interest of another family member, nor is it necessarily in the best interest of the entire family.

Further research is needed to understand to the role of culture in families and the diversity of family forms: What may be aberrant in one cultural context may be normative in another. Increasing attention to culture in family therapy has led to renewed attention to the vital importance of context in understanding and working with families.

FAMILY THERAPY FOR ADHD IN CHILDREN AND ADOLESCENTS

Attention-deficit/hyperactivity disorder, or ADHD, is one of the most common behavioral disorders of childhood. Once thought to be a disorder of childhood that could be “outgrown,” modern research has indicated that for most children, symptoms are likely to continue into adolescence, possibly increasing in severity. For some, symptoms will continue into adulthood. Intuition suggests that any chronic problem of health or behavior experienced by a child possesses potential to negatively affect immediate family members.

With ADHD, however, family members carry a greater burden. They are at the fore in experiencing the problems and stress of the disorder, and the individual characteristics and response patterns of family members, particularly parents, may influence the intensity of symptoms. Thus, parenting behavior or style might not *cause* ADHD, but family members can significantly influence the severity of ADHD symptoms over time. Additionally, parents and family members have been shown to fill a significant role in the successful treatment of ADHD. This entry provides a brief review of ADHD diagnostic criteria, prevalence rates, comorbid concerns, and prevailing theory regarding the cause of ADHD as a premise for considering the importance of family involvement in treatment of the ADHD child. The final portion of the entry summarizes specific therapeutic roles often assigned to parents as a component of treatment for ADHD.

Diagnosis, Prevalence, and Comorbid Concerns

Diagnostic criteria for ADHD are outlined in the *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition, text revision (DSM-IV-TR). ADHD criteria are largely based on empirical data although the consensus among most experts is that diagnostic refinement is necessary. Evidence of chronic, maladaptive, and developmentally inappropriate levels of inattention (e.g., failure to attend to details, difficulty sustaining attention) and hyperactive (e.g., constantly moving or fidgety) or impulsive (e.g., impatient, interrupting, reactive) behavior must be present for a diagnosis to be made. Such behaviors must be present across settings and have persisted since childhood. Finally, impairment must negatively affect function within typical childhood domains and cannot result from an alternative mental disorder.

Prevalence rates of ADHD vary dramatically depending on measurement and sampling. However, when rigorous methods are employed, prevalence estimates typically fall between 3 and 6 percent. Prevalence rates vary by age and sex of the child with younger male children exhibiting the highest rates.

Additional clinical concerns often occur comorbidly with ADHD. Rates of comorbidity vary

significantly depending on the methods employed across studies. Estimates in excess of 50 percent are common and have been observed to be as high as 80 percent. The other disruptive behavior disorders of childhood, conduct disorder and oppositional defiant disorder, are most commonly observed comorbidly. However, there is elevated risk that children with ADHD will also develop mood or anxiety disorders. The issue of comorbidity is significant because parental involvement in treatment becomes paramount when additional disorders are present.

Causes

An exact cause of ADHD has not been identified, and this is an area of fervent research. A 1998 National Institutes of Health (NIH) conference of ADHD experts concluded that despite clear links between neurobiological systems and the behaviors typical of ADHD, no clear causal explanation could be specified. Nonetheless, genetic and biological explanatory theories have been advanced and, increasingly, empirical data supports a significant, if not causal, role of biological mechanisms.

Among biologically based theories, none is more prominent than the theory forwarded by Russell Barkley. Barkley argues that ADHD reflects the child's failed ability to self-regulate, or maintain internal control over behavior. This failed ability reflects disruption of specific executive functions of the brain that require behavioral inhibition as the base from which they operate (e.g., the ability to disrupt an ongoing motor response given negative feedback). Thus, a developmental delay in behavioral inhibition sets the stage for subsequent cognitive processes to go awry.

Although ADHD may be best accounted for by genetic and neurobiological factors, inconsistent findings across these domains have led many to conclude that ADHD may result from multiple causal pathways that give rise to the varied symptom presentation observed among children.

Family Involvement in Treatment

Family involvement, usually meaning parents, is supported by multiple sources of data and is

logically consistent with current understanding of the disorder. In practice, parent involvement often takes the form of traditional behavioral parent training (BPT), which emphasizes the parent's role in managing the home environment and effectively responding to childhood misbehavior. In contrast, treatment strategies that emphasize participation of all family members have not been endorsed as a recommended practice guideline and there is a relative dearth of research examining their effectiveness in treatment of ADHD. Nonetheless, logical arguments can be made for involving all family members at certain points during treatment.

A substantial body of research has established BPT as effective in the treatment of disruptive behavior disorders. However, in the case of ADHD, questions have arisen regarding the degree to which treatment gains maintain across settings and their effectiveness in addressing the core symptoms of ADHD relative to the use of medication. Such concerns have resulted in clinical trials to assess the relative effectiveness of independent and combined or multimodal approaches to treatment. To date, the most authoritative clinical trial has been conducted by the National Institute of Mental Health and is referred to as the Multimodal Treatment Study of ADHD. Results from studies of this type have indicated that medications, parent training, and combined treatments are effective for ADHD children. Medications seem to be most effective in addressing the core symptoms (impulsivity, hyperactivity, inattention) of ADHD. In contrast, parent training appears to be less effective in addressing core symptoms, yet advantageous in that comorbid behavioral concerns improve. Parents also express greater satisfaction with this approach. These results have led many to conclude that multimodal treatments that combine medication management and BPT may be optimal.

Additional support for parent training as an effective treatment for ADHD has been attained from research designed to assess which forms of psychotherapy are most effective for children and the degree to which family involvement in therapy facilitates positive treatment outcomes. Across studies, this research has revealed that parental involvement is essential and that therapies that emphasize behavioral management strategies tend to be more effective, especially for disruptive behavior disorders.

To summarize, there is widespread acknowledgment that family members, especially parents, should be involved in the treatment of ADHD. Accordingly, the American Psychological Association has included BPT on its published list of evidence-based treatments for ADHD. Similarly, the American Academy of Pediatrics has included behavior therapy, implemented by parents, as a critical component of their clinical practice guidelines in the treatment of ADHD. An additional conclusion drawn from the NIH consensus conference on ADHD was that multimodal treatment of ADHD is an empirically supported practice that likely possesses merit beyond the use of medication alone.

Therapeutic Roles

Not all approaches to BPT or multimodal therapy require family members to fill identical roles. Variability may reflect differences in the conceptualization of treatment and the emphasis of treatment (e.g., problem-solving versus behavior management).

Available data implicate a genetic contribution to the development of ADHD. Thus, in some families, parents or siblings may also struggle with ADHD or comorbid problems and may need treatment. At a minimum, ADHD is likely to alter family interaction styles and cause burdensome familial stress. Parental involvement in therapy can lead to the development of parenting skills and strategies that will minimize stress in the home environment and aid parents in properly caring for themselves. Traditional family therapy may also be a method for securing valuable treatment for multiple family members and has been incorporated in some multimodal treatments that hold promise in ADHD treatment.

Parents also can facilitate treatment success by providing external prompts and guides that encourage the child's engagement in acts of behavioral inhibition. In this sense, parents may cue a child's appropriate response in a challenging situation and reinforce appropriate behavioral display, thereby increasing the likelihood of similar behavior over time. Additionally, parents can engage the child across settings, which is hypothesized to promote generalization of the child's adaptive behavior.

Education regarding the cause, nature, and prognosis of ADHD is an important aspect of treatment. Participation in learning about ADHD is a relatively universal role of family members during treatment. Through this process, parents and siblings can become advocates for the child with ADHD, misconceptions of the disorder can be corrected, and family members are able to experience a degree of empowerment as understanding is enhanced and problem behavior becomes more predictable.

Participating in BPT is a common role of parents in therapy and involves teaching parents to understand and manage problem behavior that is often pronounced and disruptive among ADHD children. Parents are (a) trained to manage their attention carefully and use BPT strategically to shape childhood behavior, (b) encouraged to utilize developmentally appropriate commands and implement positive and negative consequences (e.g., praise, time-out) in relation to compliance, (c) provided information regarding the effective use of home rules, and (d) instructed in maintaining a home token economy (a system of behavior modification based on the principles of operant conditioning that is carried out by family members at home), in managing problem behavior in community settings, and in partnering with school administrators to address issues related to homework and school performance. Length of treatment within a BPT framework varies but usually requires between 10 to 20 hours of direct therapeutic contact. Therapy is typically implemented in a stepwise fashion wherein parents attend weekly therapy sessions, are trained to implement core strategies within the home environment, and are provided ample opportunity for practice via role play and feedback within sessions. Parents then implement strategies within the home environment between sessions. In most instances, weekly data are collected to monitor treatment progress and therapy typically concludes when core behavior management skills have been implemented and child behavior has markedly improved.

It is not uncommon for older children and adolescents with ADHD to exhibit social skill deficits and experience social isolation. Social skills training is a common treatment target for older youth and may represent an opportunity for family participation in therapy. As a result of participation, parents and siblings are able to model appropriate

social skills in home environments and can directly engage the target youth in social skills practice and feedback outside of therapy sessions to promote generalization. Similarly, family members may be trained in methods of effective communication and may gain experience in implementing useful problem-solving strategies. For families of adolescent youth with ADHD, such strategies may be crucial for minimizing stress and parent-child conflict while facilitating solution-oriented interactions. Indeed, in the absence of family involvement in the treatment of ADHD, negative effects of the disorder would likely be compounded as family members would remain at risk for misunderstanding and reacting in an unhelpful or ineffective manner.

FAMILY THERAPY FOR ADULT PSYCHOPATHOLOGY

Psychiatric disorders, like physical illnesses, can have a profound effect on the family, and conversely, family support can have a major impact on the course and outcome of both types of disorders. Family therapy for adult psychopathology describes the use of psychotherapeutic treatments focused on the entire family, rather than just on the individual, to improve the management and outcome of a mental illness in one or more of its members. This entry begins with a brief history of early theories of mental illness that suggested the family played a key role in the cause of psychiatric disorders. Next, the emergence of the stress-vulnerability theory of psychiatric disorders is described, which posits that the onset and course of psychiatric disorders is the result of a dynamic interplay between biological factors, individual psychological factors, and the environment, including the family. This more modern and broadly accepted model provides a general framework for understanding the role of the family in the treatment and management of psychiatric disorders. The goals of family therapy in the treatment of mental illness, based on the stress-vulnerability model, are described. Finally, methods and approaches to working with families are described, concluding with a description of a typical family therapy session.

The term *family therapy* has been used by some to refer to psychotherapeutic approaches designed mainly to explore family dynamics and develop insight into the nature of their problems and by others to refer to a broader variety of treatments. This entry adopts a broader definition of *family therapy* to include a wide range of treatment methods, including providing family members with information about psychiatric illness (or education), teaching skills for reducing stress in the family and improving the quality of communication, addressing conflict between members, involving family members in the treatment of a member's psychiatric disorder, and helping individuals develop insight into issues such as relationship problems and the effects of mental illness on family dynamics.

Brief History of Family Therapy for Psychiatric Disorders

It has been known for more than 100 years that most psychiatric illnesses “run in families”; that is, someone with a mental illness is more likely to have a similarly afflicted relative than is another person with no such illness. In addition, it has long been recognized that families who have a member with a psychiatric disorder often have dysfunctional and stressful relationships. These two observations were pivotal in leading to early theories that proposed mental illnesses were the product of disturbed family interactions and relationships. For example, one influential theory hypothesized that schizophrenia was the result of aberrant childrearing by a “schizophrenogenic mother,” and a related theory speculated that contradictory messages from parents to a child led to an impasse or “double-bind” for which no rational solution existed, thus leading to psychosis and schizophrenia.

Based on theories that disturbed family relationships were at the root of adult psychopathology, early forms of family therapy sought to address relationship problems by fostering insight and making previously covert beliefs and power structures more explicit. It was hypothesized that helping family members develop insight into these problems would enable members to correct them and thereby eliminate the psychiatric illness.

Central to these approaches to family therapy was the assumption that the disturbed behavior and functioning of a member diagnosed with the “mental illness” reflected underlying problems in the family, rather than simple pathology in the individual himself or herself. Thus, these approaches targeted the whole family, rather than the individual with a psychiatric disorder. Although the ill member was conceptualized as “the identified patient,” the whole family was actually understood to be ill. For example, using a family systems approach, the therapist may prompt a family to recognize that the parents have become distant from each other and have substituted close relationships with their children to meet the parents’ emotional needs. As they grew into adolescence and adulthood, the children may have experienced the tension of striving for independence while not wanting to leave their parents unsupported. Within a family systems approach, this tension may have led to any of the psychiatric illnesses that often develop in late adolescence or early adulthood (depression, substance use, schizophrenia, eating disorders), and it is thought that these may improve if the parents become closer again and rely less on their children to meet their emotional needs.

Although family therapy models based on these theories dominated until the 1960s and 1970s, a confluence of factors led to a gradual shift in how mental health professionals conceptualize the role of families. First, growing evidence indicated that many psychiatric disorders have a biological basis, with vulnerability to specific disorders often passed down through genetic transmission, although it was also understood that environmental factors played a role in the specific expression of the underlying genetic defect. Research showed that the biological children of a mother with a mental illness were at increased risk for developing that illness, even if they were reared by an adoptive mother. These findings provided an alternative explanation for the observation that psychiatric disorders tend to aggregate in families. Other findings bolstered the hypothesis that biology, especially prenatal and natal factors, played an important role in the development of psychiatric disorders. For example, in research conducted on the survivors of World War II, it was found that the children of mothers who experienced severe distress (perhaps because of lack of food or death of a partner) during the second

trimester of pregnancy had subsequent higher rates of psychiatric illness than do those who experienced this stress in the first or third trimester. The unique impact of distress in the second trimester was thought to be because this is when the baby’s brain is developing the most. Similarly, in the 1950s and 1960s, a range of different psychotropic medications were discovered to reduce or eliminate some of the most severe symptoms of psychiatric disorders, including psychotic symptoms (e.g., delusions, hallucinations), depression, anxiety, and severe mood swings. The dramatic effects of these medications on psychiatric symptoms suggested biology played a significant role in the development and maintenance of many psychiatric disorders.

As more was learned about the biological nature of mental illness and its interactions with the environment, mental health professionals began to shift from viewing the family as a culprit toward seeing relatives as potential allies in treating psychiatric disorders. One key to this change in approach was the emergence of the stress-vulnerability model of psychiatric disorders, which provided a new conceptualization of the role of the family in the treatment of psychiatric disorders. This theory is broad enough to encompass most serious psychiatric disorders and is briefly described in the following section.

Stress-Vulnerability Model of Psychiatric Disorders

The stress-vulnerability model proposes that the onset and course of psychiatric disorders is determined by a combination of biological vulnerability and environmental stress. According to the model, biological vulnerability to a specific mental illness is a necessary condition for someone to develop that disorder, with vulnerability being determined by a combination of genetic and other biological factors, such as obstetric complications. Biological vulnerability interacts with stress in the individual’s environment to increase the chances that he or she will develop a psychiatric disorder and to worsen the course of the disorder. Biological vulnerability can be reduced by medications or worsened by substance abuse. Furthermore, substance abuse can lessen the protective effects of medication on vulnerability.

Just as biological vulnerability can be modified, so can absolute levels of stress, as well as sensitivity to stress. High levels of conflict and stress can worsen outcomes (e.g., frequent fighting in the home, criticism of the ill person). However, the effects of stress on vulnerability can be reduced by increasing social support from family members and others, as well as by enhancing the individual's skills for coping with stress and symptoms and for achieving personal life goals.

Goals of Family Therapy

The stress-vulnerability model points to a variety of ways to improve the outcomes of serious psychiatric illnesses, and many of these involve the family. Family therapy teaches the family to reduce biological vulnerability and stress, while increasing social support and coping. Common goals of family therapy across different psychiatric disorders are described in the following sections.

Stress Reduction

Psychiatric disorders are characterized by a combination of abnormal and dysfunctional feelings, thoughts, and behaviors and their negative effects on relationships, self-care, and functioning at work or school or as a parent. The social nature of psychiatric disorders, combined with the natural interdependence and caring among family members, means that when mental illness develops in one person, most other members of the family are affected. Family members may be frightened, bewildered, frustrated, angry, or sad when their loved one begins to act and function differently. The illness may require relatives to attend to the ill family member's needs, to compensate for lost roles the person used to play in the family, such as worker or homemaker, and to divert time and money toward helping the relative. Thus, stress in relatives of people with a mental illness is common, which can increase stress on the person with the illness and inadvertently worsen the psychiatric symptoms and increase the likelihood of relapses. Reducing stress through family therapy can improve everyone's quality of life, as well as the course of the psychiatric disorder.

Improving Adherence to Recommended Treatments

A wide range of interventions is effective for the treatment of different psychiatric disorders, including medications, individual or group therapy, and psychiatric rehabilitation approaches such as supported employment and social skills training. People with these disorders who do not take their medication regularly or fail to develop coping skills are prone to frequent symptom relapses and psychiatric hospitalizations, which can be upsetting and disruptive to everyone in the family. By understanding what treatments are recommended for the relative's mental illness, family members can support the person's adherence to treatment, and receive the benefits of fewer symptoms and better functioning.

Minimizing Alcohol and Drug Use

Alcohol and drug abuse and dependence are common problems in the adult population, affecting about 15 percent of people over their lifetimes. Among people with a psychiatric disorder, rates of substance abuse and dependence are much higher, typically ranging between 25 and 50 percent over the lifetime. The increased rate of substance use problems in people with a mental illness is partly caused by their biological vulnerability to the psychiatric disorder, which makes them more sensitive to the effects of even modest amounts of substance use. In addition, people may attempt to cope with or escape their mental health problems by using substances. Family therapy aimed at reducing substance use and promoting sobriety in the person with mental illness can improve the management of the disorder and the person's psychosocial functioning.

Fostering the Development of Coping Skills

For people with a psychiatric disorder, effective coping can reduce the impact of stress and persistent symptoms and improve adaptive functioning. Individual and group therapy approaches often focus on helping people with a mental illness improve their coping and social skills. These individuals may also benefit from the support and help of their relatives in learning and practicing new coping skills. A common goal of family therapy is

to facilitate the ability of family members to help a loved one improve his or her coping skills.

Supporting the Individual's Pursuit of Personally Meaningful Goals

Having a mental illness can cause enormous disruptions in an individual's life, and interfere with daily functioning, close relationships, school, and work. Psychiatric disorders are often episodic in their course, with symptoms varying over time in severity, making it difficult to achieve consistent optimal functioning. The chronic nature of psychiatric disorders is often discouraging and demoralizing, leading some people to give up hope for improving their lives and achieving their goals. Illness education for relatives can help them play an invaluable role by believing in their loved one's ability to improve over time, instilling hope for the future, and helping their loved one articulate and pursue personal goals. Family therapy can rally the family around helping a member with mental illness develop a meaningful and rewarding life, even when symptoms persist.

Approaches to Family Therapy

Some family therapy focuses primarily on teaching participants skills and providing information on helping a relative with a mental illness. Other therapies may take a more family-systems approach, helping family members better understand their own family system, how the mental illness has affected it, and how they can better help their relative. Family therapy based on modern and scientifically informed understanding of mental illness has been shown to be effective at improving the course and functioning of individuals with a variety of different psychiatric disorders, including schizophrenia-spectrum disorders, mood disorders (e.g., bipolar disorder, major depression), and anxiety disorders. It is important to clarify what is meant by the term *family* here. In newer models of family therapy, the term applies to both families of origin as well as marital or conjugal-like dyads. In some models, it may also include adult siblings or children of ill persons or even close non-kin relationships (e.g., friends, pastors, 12-step sponsors of self-help groups such as Alcoholics Anonymous).

Family therapy approaches vary in their format, duration of treatment, and the settings in which they can be provided. Usually the patient and relatives attend together. Some approaches have families attend by themselves, but sometimes they attend in groups where they can see how other families successfully meet challenges and obtain support from others. Family therapy programs may be short term, such as several weeks to several months, or longer term, lasting 9 months or more; longer term programs are typically related to better outcomes in serious mental illnesses such as schizophrenia or bipolar disorder. Family therapy can be provided in a local community mental health center, in a psychiatric or general hospital, at a private practice office, or in the family's home.

Although different methods are used in family therapy programs, many approaches include a core set of features designed to help the family facilitate the treatment of the member's mental illness. These key features of most effective programs are briefly described here.

Illness Education

Mental illness is often not recognized and is poorly understood by people, which can lead to blaming the individual for being lazy, selfish, reckless, or undependable. Family therapy programs often seek to legitimize psychiatric disorders as genuine illnesses and to familiarize the family with the characteristic symptoms and principles of treatment. Reducing blame, increasing acceptance of the mental illness, and teaching families about treatment can reduce stress in the family and enlist the support of relatives for the member's participation in treatment.

Collaborative Stance With Treatment Providers

Early approaches to family therapy for psychiatric disorders often led to tension between family members and mental health professionals. Modern approaches aim to develop a collaborative relationship with the family. Such collaboration recognizes that families have much to contribute to helping a loved one manage a mental illness and make progress toward recovery, and that involving relatives in treatment planning and helping a

member follow through on recommended treatments can optimize outcomes. Furthermore, in the absence of collaboration, and lacking understanding of the psychiatric disorder, families may inadvertently undermine a relative's adherence to treatment. The collaborative aspects of family therapy include involving family members in treatment planning, teaching them how to monitor the illness and to develop relapse prevention strategies, providing them with easy access to treatment providers to obtain information and alert providers to significant changes in their relative's disorder, and helping them develop strategies for facilitating their loved one's adherence to recommended treatments, such as taking medication, attending individual/group therapy appointments, participating in psychiatric rehabilitation programs, and following through on therapeutic homework assignments to practice specific skills related to their treatment.

*Focus on the Here-and-Now and Future,
Rather Than on the Past*

The primary emphasis of most newer effective models of family therapy for a psychiatric disorder is on the present and the future, positing that there are limited benefits to dwelling on the past, and that the preponderance of work to be done involves helping the family develop the knowledge and skills to manage the mental illness and promote improved functioning for the relative.

Improving Communication and Problem Solving

All families have to deal with conflicts and problems, and difficulty handling problems effectively can lead to strain, even in the absence of a mental illness. When a close family member has a mental illness, the number of problems often multiplies, increasing stress and tension, and resulting in a breakdown of effective communication and problem-solving skills. This added stress can contribute to relapses of the psychiatric disorder, further worsening the strain on all members. Family therapy programs typically aim at improving the quality of communication between members and their ability to solve problems cooperatively.

Format of a Typical Family Therapy Session

There are many kinds of family therapy. However, a typical 50-minute individual family therapy session, often attended by the patient and two or three relatives, might have the following structure: The session might begin with the therapist inquiring if there had been any emergencies or problems during the week and addressing them, and then asking about completion of any homework assignments (e.g., practice on a communication skill taught the previous week). The therapist and family would then review how family members had used the skills during the week, and each would get a chance to practice (i.e., to "role-play") the skill in the office to ensure he or she could use it well; other family members would give constructive feedback. The therapist would then introduce another skill—perhaps another communication skill or an effective method to do problem solving—and everyone in the family would then practice that skill in the session, with members giving feedback on what each did well or might improve. The therapist would then ask the family to practice the skill at home and might provide homework sheets to record their efforts for review at the next session.

FAMILY THERAPY FOR NONCOMPLIANCE IN CHILDREN AND ADOLESCENTS

Noncompliance (NC) is generally defined as a child's failure to follow directions, instructions, or commands and reflects disregard toward authority figures. In research contexts, NC is operationalized using specific details that promote reliable measurement (e.g., the failure to initiate an appropriate or expected response within 5 seconds following a command). In fact, there are many different forms of NC (e.g., NC to commands, NC with rules).

NC is a relative term that must be considered within a developmental context and requires that *compliance* is possible. For example, the absence of compliance with instruction from a 1-year-old child is rarely viewed as noncompliance and is qualitatively different than the response of a 2-year-old child who says "no" when told to do something he or she prefers not to do. However, each describes a possible outcome when considering the defining characteristics of early childhood developmental processes (e.g., emerging verbal ability, establishing identity, display of self-expression, emerging autonomy) relative to the complexity of the command (e.g., use of familiar terms, simple, direct, meaningful).

NC becomes a behavioral concern with clinical implications when it occurs (a) outside of expected developmental stages, (b) with significant frequency, or (c) when it is experienced as unmanageable. In these circumstances, NC may be viewed as atypical.

Certain types of NC, direct (blatant acts of defiance accompanied by anger) and passive (ignoring), are of particular concern because they may reflect limited social development and are predictive of later disruptive behavior problems. Atypical NC has been referenced in the research literature as a *keystone* behavior in the development of disruptive behavior disorders because it is a stable, behavioral precursor of emerging antisocial behavior. Within this entry, NC is considered from a diagnostic perspective and prevalence rates and comorbid concerns are briefly reviewed. Hypothesized causes of atypical NC are considered along with the importance of family involvement in its management. Finally, the therapeutic roles of family members are considered within the context of evidence-based approaches to treatment.

Diagnosis, Prevalence, and Comorbid Concerns

NC is a negative behavior often observed among children and is most prevalent during preschool years. In fact, disruptive behaviors (e.g., noncompliance, tantrums, sibling conflict) are the most common concerns voiced by parents to pediatricians during pediatric primary care clinic visits and persist as the most frequent referral concern among older children referred for mental health services.

Research suggests that a substantial portion of youth who display chronic and severe disruptive behavior during later childhood and adolescence also displayed significant behavior problems during early childhood. This has lent empirical support to the notion that early, chronic, disruptive behaviors (e.g., NC) may be developmental precursors of subsequent antisocial behavior.

Most children exhibit occasional NC. It has been reported that 50 percent of parents of children (ages 4–7) in nonclinical samples indicate that disobedience is a problem in the home setting, but 85 percent of parents of clinic-referred children (age 4–7) indicated that NC is a concern. There is little disparity across nonreferred and referred samples of preschoolers, with nearly 60 percent of all children displaying disobedience at least occasionally. However, there is a decided shift among school-age children: Approximately only 40 percent of nonreferred children and nearly 75 percent

of referred children continue to display problems with disobedience.

Most children exhibit at least occasional NC. Research has also estimated *how often* children who exhibit NC do so. Nonclinical samples of preschool children have been observed to be non-compliant to nearly 40 percent of parental commands whereas clinic-referred pre-school children fail to comply at a rate of nearly 60 percent. In sum, it appears that most young children display NC as a response to approximately half of appropriately delivered commands. Further, higher rates of NC are displayed by clinic-referred children.

NC is a behavior with which many parents must contend. Recall that atypical NC (e.g., developmentally inappropriate, frequent displayed, experienced as unmanageable) is more likely to trigger clinical concern and may be the primary target of clinical intervention but does not function as the independent basis of formal diagnosis. The primary comorbid concerns associated with NC are additional disruptive behaviors (e.g., tantrums, verbal aggression). Formal diagnosis of a disruptive behavior disorder requires clustering of multiple disruptive problems within a limited timeframe.

The *Diagnostic and Statistical Manual of Mental Disorders* specifies criteria for the primary disruptive behavior disorders of childhood, including oppositional defiant disorder (ODD). NC is the prominent feature of ODD, making this the likely diagnosis when atypical NC is the primary clinical complaint. ODD is defined as a consistent pattern of negativity, hostility, or defiance directed toward authority figures such as parents and teachers. Specific diagnostic criteria require that at least four of eight problematic behaviors be present during a 6-month period. Primary behaviors to be considered include loss of temper, arguing with adults, refusing to comply with adult requests, deliberately annoying others, blaming others for one's mistakes, being easily annoyed by others, displaying anger or resentment toward others, and engaging in spiteful or vindictive behavior. In addition to these concerns, impairment (typically social or academic) must be present and problem behavior cannot be better accounted for by some other psychological problem. ODD is most commonly observed among younger children with prevalence rate estimates observed to range from 2 percent to as high as 15 percent.

Causes

The relatively common display of NC during early childhood appears to be closely linked to critical aspects of development. NC is likely to be observed within the first 2 years of life and has been observed to peak in frequency around the third year of life. Subsequently, rates of NC decline, and this is thought to be linked to the child's cognitive (e.g., problem-solving ability, verbal competence) and social (e.g., awareness of others, emotion regulation) development but is undoubtedly also influenced by environmental response (e.g., reactions of siblings and parents).

Evidence has accumulated suggesting that genetic inheritance may contribute to the display of NC. Child temperament (e.g., stable, seemingly reflexive behaviors exhibited in response to environmental stimuli), as an expression of genetic influence, may mediate the display of atypical NC. The exact contribution of temperament to the display of NC remains unclear but behaviors associated with specific temperamental styles (e.g., aggression, emotional reactivity, resistance to being controlled by others) may be involved.

As mentioned previously, NC has been described as a keystone behavior in the development of childhood antisocial behavior. A prominent theory, termed the *coercive model*, posits that significant disruptive behavior problems develop as a result of enduring chronic, negative, and intense parent-child interactions wherein each attempts to coerce or control the other and is reinforced for doing so. The model asserts that the onset of these negative interactions is linked to the child's display of typical misbehavior (e.g., noncompliance during preschool years) that parents fail to manage effectively. What begins with ineffective interactions related to something as simple as NC may develop into a display of chronic disruptive behavior. Within this model, a number of risk factors have been identified (e.g., child temperament, parent psychopathology, family discord, limited attachment), and it is hypothesized that the combination of a subset of these along with problem behavior (e.g., NC) and ineffective parental response yields a pattern of future disruptive behavior problems.

Family Involvement in Treatment

NC may be the sole target of treatment; however, it is more likely to be part of a cluster of behavioral concerns related to the diagnosis of ODD. Nonetheless, NC is a primary target of treatment given its hypothesized prominence in the eventual development of behavioral concerns. The most effective treatments for ODD align closely with the coercive model that was described previously and are designed to directly target parenting skill deficits. Thus, parents and the target child are primarily involved in treatment, although parents are encouraged to incorporate siblings as warranted. Treatment is generally referred to as behavioral parent training (BPT), and although there are multiple types of BPT programs, they overlap considerably in their approach to treatment. The primary goal of BPT is to enhance parent understanding of disruptive behavior (e.g., NC, tantrums, aggression) and to promote mastery in implementing basic behavioral management skills within the home environment. BPT is considered to be a “best practice” in the treatment of ODD and is usually offered as the first line of treatment. Data indicate that BPT is more effective than a variety of other therapies (e.g., parent or child individual psychotherapy, play therapy) in treating ODD.

The typical format of BPT requires attendance and participation of parents and the target child. Both parents may not be required to attend, although this is usually strongly encouraged. Therapy sessions are typically 1 to 2 hours in length and families are asked to attend anywhere from 6 to 20 sessions. Treatment progress is carefully monitored and is a primary factor determining the duration of therapy. A typical session involves a review of treatment progress and completion of therapeutic homework since the last session; direct instruction with parents in the use of a target parenting skill; and within-session application of the skill via a combination of modeling, role-playing, and direct interaction with the target child. Therapeutic homework typically involves home and community implementation of the target skill. For example, parents may be coached to deliver effective commands as a skill that promotes compliance. As homework, parents would then be expected to practice and record their success in using this skill within the home environment.

Therapeutic Roles

Within BPT, the primary therapeutic role of parents is that of *primary treatment provider*. BPT acknowledges that few measurable changes in parent or child behavior are actually achieved within therapy sessions. Rather, treatment gains are achieved as parents implement effective skills and strategies with consistency, within natural living environments. Thus, parents manage and implement the treatment, and the therapist provides training and support for the parents.

As the primary treatment agent, parents are taught to fill key parenting roles. These roles include (a) monitoring their child’s behavior across settings to detect instances of appropriate and inappropriate responding, (b) using positive consequences (e.g., praise, attention, tangible rewards) to strategically encourage prosocial behavior, (c) using positive and negative consequences (e.g., timeout, privilege loss) to alter environmental contingencies and teach new behavior, and (d) engaging in family-based problem solving as needed, while (e) maintaining positive parental involvement (e.g., developing family traditions, scheduling family activities, participating in the child’s extracurricular activities) over time.

Family dysfunction (e.g., parental psychopathology, marital dissatisfaction/conflict, low socioeconomic status) yields increased risk that a child will develop atypical NC or drop out of treatment prematurely. However, addressing such familial concerns is beyond the scope of BPT. Consequently, BPT may be combined with various other treatment strategies in an approach that is termed *behavioral family therapy* (BFT). Within BFT, parents and siblings may fill expanded treatment roles that directly benefit the target child and the family system. For example, a parent may participate in individual psychotherapy to address a personal addiction, parents may participate in marital counseling to improve aspects of their relationship, or parents and siblings may become involved in accessing community resources to relieve specific family burdens (e.g., participating in afterschool study programs, using public mass transportation).

FAMILY THERAPY FOR SUBSTANCE ABUSE IN ADOLESCENTS

Adolescent substance abuse research has emerged from the shadows of the adult drug abuse field and entered a new developmental stage. Policymakers, treatment providers, and funding agencies now recognize this scientific area for its uniqueness, theory base, clinical model diversity, and accumulating body of basic and applied research. These constituencies have become more interested than ever in supporting adolescent substance abuse research. However, as is the case with all new developmental periods, this one has unique risks, opportunities, and challenges. This entry discusses family therapy—one of the most exciting advances in the adolescent drug abuse specialty.

New Conceptual Approach to Teen Drug Problems

Steady professional, lay public, and media interest has been fueled by the continuing problem of

adolescent substance abuse and related difficulties, by its far-reaching public health implications, and by a growing awareness that adolescent drug problems are best understood as a set of complex, multilevel behaviors. Simultaneously occurring problems—interpersonal difficulties, family, school, and legal problems—interact, and in clinical samples are more often the norm than the exception. As a heterogeneous disorder, there are multiple pathways to drug taking and drug abuse, and it has multiple short-term and longer term consequences for interference in development as well, involving many aspects of adolescent functioning. Basic science advances in nosology, classification, assessment, and life-span human development have enhanced treatment, but made it more complex to do. The challenges for teaching this kind of therapy and transferring it to nonresearch settings are just beginning to be recognized.

The use of developmental knowledge to guide understanding of adolescent problem behaviors and adolescent substance abuse has been transformative. Today, clinicians and researchers base their work on specific developmental principles derived from developmental psychology and psychopathology. The importance of parental monitoring in the context of the ongoing and emotionally involved and supportive parent-teen relationship, the growing influence of peers throughout the adolescent years, and how this fact, among other developments, necessitates a renegotiation of the parent-adolescent relationship are examples of essential knowledge for clinicians. The variety of new, clinically useful knowledge that has been developed is impressive. In addition to the systems level content just mentioned, researchers have established that individual level factors, including difficulties in one's assumptions about the unharfulness of drug use or problems of impulsivity and sensation seeking, interact synergistically with familial and environmental circumstances to increase a teen's risk of developing drug problems. Research reveals a simple and rather daunting equation—as the number of risk factors increases, the probability of a teen developing drug and other problems increases as well.

These types of knowledge-building advances in the basic science of adolescent substance abuse and related problem behaviors have established a foundation for significant changes in treatment

development and research. Although the policy implications of these changes have yet to be fully realized, contemporary treatments for substance abusing teens, particularly family-based treatments, differ on many dimensions from previous forms of intervention. Beyond the parameters of today's treatments being different from earlier periods, however, the interventions are more effective as well. Whether one considers engagement or retention rates, the expanded capacity to decrease or eliminate drug taking or behavior problems, how contemporary treatments produce demonstrable increases in protective factors in the teen's and family's life (i.e., putative change mechanisms such as changes in family functioning, increased bonding to school, decreased affiliation with drug-using peers), or the extent to which new interventions are disseminated widely through novel and expanded communication and institutional outlets, contemporary approaches are superior to earlier generation models.

Clinical Methods Target Known Determinants of Drug Use and Problem Behavior

Contemporary adolescent treatments target research-derived, well-defined, and in most cases easily assessable risk factors. Behaviors and contextual circumstances known to be related to the development and maintenance of drug and other problems include such things as the quality of the parent-teen relationship, authoritarian parenting practices, conflict or emotional disconnection in the day-to-day family environment, and the parents' own history of and current substance use, mental health functioning, and criminal justice involvement. These aspects of the teen's proximal social ecology are important to all aspects of youth development and everyday functioning, as well as to atypical development, so these dimensions are prime intervention targets in changing a teen's drug taking. How knowledge about the most desirable treatment targets is used in clinical work pertains to the intervener's abilities, to the approach followed, and to the specificity of the protocols used within that approach to address the target areas. For example, empirically based family therapy models focus on parenting practices, a parent's psychological functioning, and the teen's individual characteristics and developmental deficits.

Family therapy models intervene differentially according to the stage of treatment. The initial individual meetings with a parent focus on motivating that adult to get more involved in the child's life because the teen's development is off track, and long-term well-being is in question. In therapy's second (i.e., middle) stage, clinicians teach, coach, and actively shape a parent's responses to the teen's problems in individual sessions and in meetings with the parent and youth together. Playing both sides of the interaction, clinicians help teens speak their minds and show aspects of themselves to their parents that are not usually experienced by the parents or others inside the family.

Sessions may happen in the home, in the clinic, in the waiting room at court, in the visitor's area of the juvenile detention center, or in a spare room at the school. Therapists use the structural family therapy method called *enactment* to decentralize themselves from family interviews and encourage family members to face each other, literally and figuratively, and discuss important but touchy relationship topics and recent unsettling events. These methods have in-session and longer term goals. The desired proximal outcome may be several things—to develop and practice a new way of relating, resolve past and current conflict, build a foundation for more adaptive future relating and functioning, emotional experiencing, or expand the behavioral range or repertoire in these developmentally important but underfunctioning family relationships. Success in using these methods is fundamental to overall clinical success in family therapy. Changing the individual functioning of a parent and the parent-teen relationship are instrumental to altering the youth's drug taking and other problem behaviors. Although studies have not yet established family therapy's contraindications, clinical situations where families are not physically available perhaps because they live in other countries or other states may represent a contraindication. At the same time, some family therapists have developed systemic therapies that use family therapy principles with individuals and that do not require the physical presence of the family.

Typical Characteristics of Family Therapy Models

Reflecting on these examples alone, one can see how today's treatments have become more

comprehensive. This reflects a growing belief in the field that multicomponent treatments are needed to address interconnected impairment areas in the lives of clinically referred teens. But the clinical usefulness of the risk factor research base is only one element in the evolution of adolescent drug abuse treatments. Today's adolescent treatment models also incorporate knowledge about protective factors. Protective factors are those characteristics and circumstances that combat the harmful and development-detouring processes involved in teen drug abuse. Such factors include success in and connection to school, affiliation with nonusing peers, healthy family relations, and the development-facilitating role of prosocial recreational activities (and the relationships that occur with these activities). Therapy is more than problem removal. Knowledge about teen and family development teaches therapists what to target for reduction or removal, as well as what to target for growth and enhancement. Clinicians help problem solving to improve, but also facilitate positive factors and protective forces in the youth's and family's life. Helping a teen to secure a proper school placement, get free of the juvenile justice system, develop interests in and find new prosocial, fun, non-drug-related activities are examples of the practical activity orientation within most family therapies, as well as intervention foci that "grow" protection in as many areas as possible of the teen's life.

How treatment achieves its effects is a topic of intense and growing interest. And in this regard, process research has illuminated therapy's interior. For example, therapy process studies have revealed the instrumental role played by changes in parent functioning, such as increases in parenting competencies, in determining youth outcomes. Studies have underscored the importance of the contribution of multiple therapeutic alliances in family therapy (vs. individual therapy, where there is only one alliance: therapist-individual client) to engagement and bottom-line outcome. In family therapy, clinicians must develop working relationships with the parent and the individual adolescent, as well as with those outside of the family who are relevant to various corners of the teen's world. This includes school personnel—a vice principal or special education teacher, for example—or relevant people in the juvenile justice system, such as

a probation officer or juvenile court judge. Other process studies have clarified the nature of in-session conflict between family members, charted this conflict, and characterized it by its content, historical roots, and capacity to change when subjected to well-defined and protocol-directed therapist techniques.

Examples of Treatment Outcomes

Large-scale evaluation studies reveal that on average, outpatient treatment outcomes have improved during the past decade. Unfortunately, dropout rates are still unacceptably high, and drug-use relapse, as is the case with adults, is not uncommon. One recent U.S. national-level study found that only 27 percent of youth completed the recommended (by the program director) 3-month (once weekly) treatment dose. Although complete abstinence from alcohol and illicit drugs is the benchmark used most often in determining whether a teen has relapsed during or after treatment, adolescent treatment outcome study reviews document relatively low rates of continuous abstinence following treatment. One review noted that the average rate of continuous abstinence following treatment was 38 percent (range: 30–55 percent) at 6 months and 32 percent (range: 14–47 percent) at 12 months, and another reported a median of 39 percent abstinence (range: 16–54 percent) at 6 months, and a median of 44 percent abstinence (range: 25–62 percent) at 12 months.

Overall, however, many advances have been made in adolescent drug abuse treatment and research. State-of-the-science treatments change the drug abuse of teens (e.g., more than 50 percent reductions in drug use) and key aspects of the teen's environment (family, connection to school). Treatments can maintain these kind of effects, in many cases for a year or more beyond the termination of relatively short-term (outpatient, once a week, for 4–5 months) therapy programs.

Most studies report family therapy as producing significant reductions in drug use following treatment. In one study examining 30 outpatient programs, average drug usage at discharge decreased to approximately 50 percent of pretreatment levels. Other research reported a 50 percent reduction in average drug usage at 9 months' posttreatment

for adolescents in family therapy groups and for those whose parents attended parent support groups. Family therapy studies also typically report changes in other functional areas of the teen's life, including delinquency (arrests, time spent in out-of-home detention or placement) and mental health problems (internalizing and externalizing problems). A recent influential review found family therapy to be more effective than other forms of nonfamily outpatient treatment (individual therapy, adolescent group therapy, family drug education, or meetings with probation officer) in five of six studies.

Important Current Developments

As is often the case, the more the field learns, the more it needs to know. Clinically referred teens have a harder time benefiting from treatment, although clinicians do not yet know if this is because the treatments are not yet sufficiently complex to intervene in all the necessary ways. Adolescents involved in the juvenile justice system need far-reaching services in addition to the core treatment interventions that typically are provided and that target drug use and other individual and family problems. Individually tailored treatments that are culturally or ethnically sensitive or gender specific exist but are thought to be at an early stage of development. Although evidence indicates that culturally specific therapies can be advantageous in some respects (in treatment engagement, for instance), researchers do not know if these therapies are likely to enhance outcomes (e.g., drug abuse) with diverse subgroups of teens.

Conclusion

Family therapy approaches have been involved in some of the most extensive research of all available adolescent substance abuse therapies. Research reviews and meta-analyses have discussed the comparative superiority of family therapy for adolescent substance abuse. Several approaches have been developed in one or more studies, and some of these treatments have been in use for two and a half decades. New models translate this knowledge into clinical interventions for working with parents, teens, and families,

as well as with the teen's extrafamilial psychosocial ecologies. Interventions target the individual parent and teen (cognitive schemas, emotional expression capacities, communication skills, behavioral range in problem solving, and flexibility, for instance), the family transactional patterns, and also the teen and parent relative to their functioning with and interaction in important systems outside of the family. Rigorous research has established the effectiveness of family therapy for teen drug problems, and current studies are testing this method's transfer potential in diverse clinical settings. This new generation of studies may yield a new level and kind of contribution of the family therapies for adolescent drug abuse to the field.

FATAL ATTRACTION

Fatal attraction refers to a relationship process in which a quality that an individual comes to dislike in an intimate partner closely relates to one that was attractive and initially appealing. The disliked quality often appears as an exaggerated form of the originally attractive characteristic. This phenomenon is termed *fatal*, not because it is “deadly” to the involved individuals nor necessarily deadly to the relationship itself. Rather, it foretells a sequence in which the initial attraction unlocks an inevitable progression that ends in disenchantment with a partner. The quality that was initially considered attractive becomes undesirable. Fatal attractions are relatively common in intimate encounters, occurring in between 29 and 67 percent of intimate relationships, depending on the sample and research design. This entry provides common illustrations of fatal attractions, provides a social exchange perspective to fatal attraction, and discusses potential ramifications for relationship dissolution.

Following are illustrations of several common types of fatal attractions that have been documented in empirical studies. In this research, individuals report the qualities about a partner that initially attracted them and then later describe the qualities that they now dislike about that same person.

- *Nice to Fake*: Some people report being attracted to their partners because they viewed them as nice, caring, and sensitive. In fatal attractions of this type, they subsequently report that their partners now are overly nice or even fake. In such cases, it appears that seemingly nice, sensitive, soft-spoken, and caring partners are later viewed as having traits that are the consequence of being *too* nice.
- *Confident to Cocky*: Another common fatal attraction occurs when individuals are attracted to confidence and intelligence in another person, but then report that they now dislike their partner’s egotistical, or overly confident, nature. In such cases, it seems that they reinterpret their spouse or partner’s desirable qualities in a negative manner. Originally, the loved one is seen as exuding confidence, but later that same person is viewed as displaying an ego.

- *Fun to Foolish*: Another type of fatal attraction involves qualities related to fun or humor. Individuals report that their partner’s sense of humor initially attracted them, for example, but now complain that he or she jokes excessively or fails to take other people’s feelings seriously. Having a particularly good sense of humor is both the source of attraction as well as the eventual source of friction in these kinds of relationship.
- *Sexy to Slut*: Fatal attractions also occur with regard to the trait of sexiness. In such instances, respondents report an attraction to the many physical qualities, or sexiness, of their partner. Yet when asked what they now least like about their partner, these same individuals complain that their relationship is based too much on physical aspects and in some cases, even refer to their partner in derogatory terms (e.g., “slut”). The positive trait of sexiness, in other words, appears to be interpreted as overly sexy and lustful at a later time.

One of the main theoretical traditions within the relationship field, social exchange theory, can help explain this process of fatal attraction. According to the perspective of social exchange, individuals attempt to maximize the outcomes they gain from their intimate encounters, and satisfying relationships are apt to be those in which the perceived rewards greatly exceed the costs. Disenchantment with a partner’s characteristics is likely when the costs associated with those qualities exceed the inherent rewards. For example, a committed relationship with a mate who is appealing because of his or her drive, motivation, and success at work is likely to have rewarding aspects, such as the possible prestige and money the person can bring to the couple, as well as the potential for stimulating conversations. Yet if the mate’s ambitions interfere with a couple’s time spent together, and intrude on their emotional and physical intimacy, disenchantment is likely because the relationship becomes high in costs. More generally, individuals are apt to be drawn to the noticeable strengths of another person, and those strengths are often closely related to a person’s weaknesses and therefore entail relationship costs.

According to empirical studies, fatal attractions transpire among U.S. college-age heterosexuals, married couples, lesbians and gays, and those from

various race and ethnic backgrounds. Certain romantic relationships are more susceptible to this phenomenon of fatal attraction than are others, however. According to research, individuals often become irritated with the desirable qualities of their partner that are either dissimilar from their own, extreme, unique, or strange, and they are less apt to be disturbed by the similar, appealing qualities of another.

Furthermore, although certain types of fatal attractions are more common than others, they take place with respect to a wide range of personality characteristics. There are instances of fatal attractions when individuals are drawn to any of the following major personality types in a partner: agreeableness, conscientiousness, extraversion, openness, and emotional stability. No strength, it seems, completely lacks a possible, corresponding weakness.

The findings discussed here have potential ramifications for relationship dissolution. Many accounts of breakups imply that these endings are circumstantial and out of an individual's control. Yet fatal attraction research indicates that for a substantial proportion of couples, people may play an instigative role in the demise of their relationship by selecting as a partner someone whose strengths they will eventually find annoying. The potential battlegrounds for couples are also evident. Common complaints about a mate in couples' disagreements include, for example: a lack of seriousness, domineering ways, or unpredictable and irresponsible behavior. The puzzle, of course, is that these types of grievances about a loved one frequently seem so closely related to the features initially found pleasing. The notion of fatal attraction, therefore, raises the intriguing possibility that such objections about a partner, and related dyadic conflict, may be predictable from the initial stages of a relationship. The findings bring to mind the common adage: "Be careful what you wish for."

FATHER–CHILD RELATIONSHIPS

This entry discusses father–child relationships, which encompass interactions, thoughts, and emotions between a father and his children across the life span of both. Father–child relationships shape the development and life satisfaction of both fathers and children through direct effects of father–child contacts and through indirect effects such as fathers' economic provisions for children, the quality of the father's relationship with the child's mother, and children's peers' attitudes toward parental authority. The quality, intensity, centrality, and perceived importance of father–child relationships fluctuate as both children and fathers develop and experience changes in other aspects of their lives such as schooling, work, friendships, family formation and dissolution, and coresidence. Father–child relationships have become an area of increased focus in social science research and social policy since the mid-1970s, paralleling rapidly changing norms for gender equity in work and family. Decreases in men's earning power have been accompanied by increasing participation of women in paid work. Public attention to fathering has also been fueled by debates about topics relevant to father–child relationships, such as divorce, single-parent households, teen pregnancy, nonmarital childbearing, responsible fatherhood, and paternal rights.

In developed nations, two paradoxical patterns of father–child relationships have increased concurrently: (1) greater involvement by fathers in the lives of their children and (2) growing prevalence of father absence. These trends are moderately associated with, though not solely determined by, economic status, educational attainment, and ethnicity. Middle- and upper-class fathers are generally expected to have increased involvement with their children in comparison with previous generations. Social norms pressure middle-class fathers to be involved in childcare and education in addition

to playing with children and providing financial support. Mounting evidence indicates that, on average, contemporary middle-class fathers are involved in these activities with their children to a greater degree than their own fathers were. In the lower class, by contrast, there is greater risk for father absence associated with a higher prevalence of multipartner fertility, nonresidential fathering, higher incarceration rates, and frequently shifting household composition. Generally, lower educational attainment is associated with decreased employment opportunity and barriers to providing a living wage in the legitimate marketplace. A significant proportion of fathers below the poverty level engage in illicit activities to provide economically for their families. These latter patterns are associated with increased risk for violence and judicial intervention, placing continued father involvement at risk. These divergent patterns of family life account for the simultaneous trends of greater father involvement and greater father absence. Approximately 1 in 4 children in the United States live in father-absent homes and approximately 1 in 20 live in single-father homes. Most U.S. children now spend a portion of their lives in father-absent homes because of divorce, separation or relationship dissolution, or paternal incarceration, placing increased emphasis on research, intervention, and policies that target nonresidential fathers.

Diversity of Father–Child Relationships

Relationships between fathers and their children vary based on characteristics of fathers, children, and the context of the relationships, creating extensive diversity in kind, quality, frequency, and outcomes of relationships. Father–child relationships are embedded within a complex array of changing factors.

Father–child relationships vary by differences in fathers' life circumstances and roles. Men who are acknowledged as fathers may be the biological father of the child (the procreator) or a social father (e.g., foster father, adoptive father, stepfather, father-figure, mother's current significant other). Fathers may be coresidential or nonresidential with their children, or they may alternate periods of residency and nonresidency. These differing

arrangements result in different patterns of availability and absence. They may share legal custody or not and may share physical custody of their children or not. Fathers may be employed full time or part time or be unemployed. They may be the family's sole economic provider, the primary provider, a coprovider, a minor contributor to the family finances, or an economically nonproviding father. Fathers may be primary caregivers, active coparents, or relatively or completely detached from direct interaction with their children. Fathers may be cohabiting, married, separated, divorced, remarried, or widowed. Paternal race, ethnicity, culture, and subculture represent other dimensions of diversity in the father–child relationship.

Men's developmental maturity and personal resources are another source of variability in father–child relationships. Fathers differ in psychological, social, physical, and spiritual characteristics such as mental health, intelligence, interpersonal skills, physical health, and engagement in faith communities. Fathers of different ages have unique patterns of strengths and weaknesses in personal characteristics. Variety in the timing of the transition to fathering is extensive, and men fathering children during their teen years ("early-timing" fathers) must negotiate a different set of resources and challenges than do men who delay fathering until a later age. Men who become fathers during socially defined "on-time" periods have typically completed more of their education and made further progress in establishing work or career than early-timing fathers. Late-timing fathers tend to have more financial and developmental resources than do either early or on-time fathers, but the transition to fatherhood may entail greater life adjustments for them than for "on-time" fathers. Some men view fathering to be a central or primary role in their lives, but other men view fathering to be secondary or less important than other roles or pursuits. Variety in father–child relationships also may stem from fathers' history with their own fathers and the quality and nature of their relationship with the child's mother. Men who continue in ongoing romantic relationships with their child's mother tend to be more involved with their children over time than do those who do not. These sets of characteristics interrelate with one another and are likely to change with time, influencing continuity or discontinuity of paternal involvement

with children as developmental and other changes impinge on father–child relationships.

Similarly, children’s differing characteristics introduce yet more variability into father–child relationships. Sex of the child, birth order, temperament, personality factors, health, and developmental abilities are a few of the primary factors that influence quality and amount of father–child relationship over time.

Father Involvement

Researchers and policymakers have viewed amounts and qualities of fathers’ involvement with their children as central moderators of father–child relationships and subsequent outcomes. Patterns of father involvement are related to the varied contexts of fathering and are known to be influenced by fathers’ psychological factors (e.g., motivation, the centrality of fathering identity in a man’s overall view of himself, self-confidence), biological factors (e.g., health, substance use, mental health), ecological factors (e.g., economic opportunities, cultural ideologies), public policies (e.g., judicial processes, child support enforcement, welfare reform), and social support (e.g., quality and nature of family relationships and friendship networks, fathers’ relationship history with his own parents).

Though there have been debates regarding the specific components and the best ways to understand and quantify father involvement with children, there is widespread professional agreement that developmentally facilitative “good fathering” is associated with positive outcomes for children, for fathers, for families, and for the communities in which they reside. In contrast, father absence, neglect, or maltreatment is associated with negative child outcomes unless ameliorated by consistent and substantive relationships with other caregivers.

For these reasons, recent social policies have attempted to target increasing the involvement of fathers in their children’s lives. By fostering positive father involvement, such policies may yield developmental benefits for children, fathers, and their families. However, forced compliance that exposes children to negative father–child interactions is likely to be associated with deleterious results.

Documented Differences Related to Father–Child Relationships

Linking father–child relationships to specific documented differences in developmental “outcomes” (e.g., child well-being) is challenging. Such differences are difficult to quantify precisely because the development of children occurs in the context of other relationships (e.g., mother, siblings, extended family, peers, teachers, mentors, clergy) and contexts (e.g., extrafamilial care, schooling, mass media, and cultural scripts) that shape development. To unequivocally demonstrate causal links between particular kinds of father–child relationships and child outcomes, experimental studies would be necessary. For ethical and practical reasons, controlled experiments on father–child relationships are not possible. Further, developmental “outcomes” are best thought of as snapshots of functioning at a particular time and as subject to measurement challenges and subsequent change. Nonetheless, a confluence of research studies and theories makes it clear that father involvement contributes to shaping child development outcomes and the kinds and amounts of father involvement influence child outcomes.

Father involvement affects child outcomes differently by gender and age of the child, as well as by the quantity and quality of father involvement over time. Outcomes may be examined in terms of physical, cognitive, psychological, social, and spiritual development in both children and their fathers.

When child well-being is measured in more global and quantitative ways, positive father–child relationships are associated with greater academic attainment in children (test scores, grades, graduation rates), lower rates of juvenile delinquency, fewer conduct problems, less substance use, and lower teen pregnancy rates. In developing nations, father involvement in provision and protection is linked to child survival rates. Measures or assessments that are more qualitative and process-oriented connect positive father–child relationships to better social adjustment and skills in children (e.g., popularity, leadership, life satisfaction), greater self-esteem, and lower depression.

Involved fathers report that they are better people for having engaged in involvement with their children. They describe perceived positive changes in responsibility, maturity, health, and life

satisfaction and meaningfulness. Though involved fathers can articulate personal as well as financial costs of having children, they tend to view the costs to be outweighed by the benefits that they have experienced.

Factors of Importance in Father–Child Relationships

Because of the varied father–child relationships evident across the many contexts in which families live, the social science literature presents many different views of father–child relationships. Yet a careful review of research studies and prominent theories brings a focus to a select set of factors in father–child relationships that always matter, regardless of the gender or age of the child, the context of interaction, or other circumstantial factors. These factors could be identified as (a) the emotional climate of the relationship, (b) fathers' behavior, and (c) the interplay of the relational climate and behavior. When the *emotional climate* of the father–child relationship is focused on mutual warmth, trust, love, attachment, security, provision, involvement, connection, protection, and “being there,” both fathers and children develop more positively than when these factors are lacking or negativity, neglect, or harshness is present. When the father's behavior is characterized by moderate control and high warmth, responsiveness to questions, appropriate interest in their children's lives and interests, monitoring and attentiveness to them, availability, and frequent interactions with the child, father–child relationships are considered to be of higher quality than when these behaviors are not present. Such father behaviors are associated with positive father–child relationships, and better psychological and social adjustment for children. The central attributes of “good fathering” can be partially facilitated and supported through training and intervention programs for families experiencing lack in these areas.

As children mature and can reciprocate fathers' interests and needs, mutually positive father–child relationships can extend across the life span. Both fathers and children report that positive father–child relationships are meaningful in shaping life meaning and satisfaction.

FEAR OF DEATH, RELATIONAL IMPLICATIONS

Fear of death is a universal human attribute, the avoidance of which is the motivational impetus for a substantial proportion of human behavior. Given the fundamentally social nature of our species, it is not surprising that close relationships, such as those between family members, friends, and romantic partners, are greatly influenced by concerns about mortality. This entry provides an overview of how fear of death relates to the development and maintenance of close relationships.

Anthropologist Ernest Becker proposed that the uniquely human awareness of death gives rise to potentially paralyzing dread that is assuaged by culture. Cultural worldviews consist of humanly constructed beliefs about the nature of reality that provide a sense of meaning and value. Every culture has an account of the origin of the universe,

prescriptions for appropriate conduct, and promises of either symbolic or literal immortality to those who meet or exceed standards of value. Research based on terror management theory supports Becker's claims by demonstrating that (a) self-esteem (the belief that one is a person of value in a world of meaning) reduces anxiety in response to threat, and (b) reminders of death (mortality salience) instigate efforts to bolster faith in one's cultural worldview.

Introducing Death Into the Science of Love

Recently, theory and research have documented the importance of close relationships as a third psychological resource (in addition to self-esteem and cultural worldviews) that affords protection against the potential terror engendered by death awareness. According to John Bowlby's Attachment Theory, the anxiety-buffering function of close relationships develops in early childhood, as highly immature and vulnerable infants' undifferentiated fears in response to threats impel them to maintain physical and emotional proximity to primary caregivers. (Such "attachment" is evolutionarily advantageous by keeping vulnerable babies close to be protected by their caregivers.) "Secure" attachment to caregivers—that is, the confident dependence of a child who appraises his or her caregiver as likely to respond to the child's distress—alleviates anxiety and promotes growth-oriented activities such as exploration, play, and affiliation. Thus, even in young children, fears related to self-protection, though preceding explicit death awareness, instigate the formation and maintenance of close relationships.

Parental provision of protection and sustenance provides children with positive feelings of safety and satiety and is at first provided unconditionally. During socialization, however, parents' approval becomes contingent on engaging in certain culturally prescribed activities (e.g., standing for the Pledge of Allegiance) and refraining from others (e.g., urinating in the swimming pool). Now children learn to associate feeling safe and secure with being "good" and anxiety and insecurity with being "bad." This is how self-esteem initially becomes an effective anxiety buffer: positive self-feelings are remindful of parents' love and protection.

Later in childhood, youngsters realize that their parents are human and mortal and, thus, ultimately incapable of protecting them from life's dangers. Coincidentally, children recognize the inevitability of their own death. These developments compel children and adolescents to develop or adopt beliefs about the world that address existential issues, such as the origin and purpose of life and the meaning of death, in emotionally soothing ways. Consequently, they begin to (quite unconsciously) transfer their psychological allegiance from parents to the cultural worldview and garner self-esteem by adhering to standards of value associated with their social roles as fledgling members of their culture, in pursuit of literal (e.g., an after-life) or symbolic immortality (e.g., living on through one's accomplishments or progeny).

Because of the developmental interconnectedness among close relationships, self-esteem, and worldviews, all three mechanisms function interdependently to maintain psychological equanimity in adulthood. Research has demonstrated that securely attached individuals (similar to those with high self-esteem) are less likely to respond defensively to reminders of death. Additionally, death reminders increase the desire for intimacy, affiliation, willingness to initiate social interactions, and commitment to existing romantic relationships. Moreover, when close relationships are threatened, people become more insecure and subconscious thoughts related to death become more active. Current research also demonstrates that threats to one of the three anxiety-buffering mechanisms (attachment relationships, self-esteem, or cultural worldviews) instigate compensatory activation of the other mechanisms, suggesting that the three function as a coordinated security system.

Summary and Conclusion

In sum, human beings are prone to existential terror by virtue of their awareness of the inevitability of death, which can occur at any time for reasons that are often unanticipated and uncontrollable. Infants secure psychological equanimity by forming close emotional bonds to significant others, and security is subsequently fortified as individuals embed themselves in a cultural worldview and believe themselves to be valuable

contributors to the meaningful universe that the worldview describes. Close relationships, cultural worldviews, and self-esteem are all thus essential components of effective management of death fears. However, because close relationships are forged in infancy, long before we are aware of death or the cultural constructions we unknowingly adopt to cope with mortality or the psychological gyrations we employ in our incessant pursuit of self-regard, they may be the most potent and effective psychological bulwark against the ravages of time. As the great Roman poet Virgil put it more than 2,000 years ago: *Omnia vincit Amor*—Love conquers all!

FEMINIST PERSPECTIVES ON RELATIONSHIPS

Feminist perspectives on relationships are found not in a singular theory but, rather, in a variety of

interdisciplinary perspectives that value women's lives and experiences and seek to understand how gender is systematically constructed and performed in ways that naturalize social inequities and difference. This entry discusses common themes of feminist perspectives on relationships: gender as a social construction, intersectionality, power dynamics (both interpersonal and structural), historic and sociocultural contexts, rejection of unitary and uncomplicated notions of relationships and families, and methodologies that embrace deconstruction, reflexivity, and acknowledged politicized inquiry.

The Social Construction of Gender

As a central component of their theorizing, feminist scholars view gender as a social construct that embodies cultural views of femininity and masculinity; in this view, gender is created through everyday practices, interactions, and institutions that shape our ideas and enactment of what it means to be male and female, masculine and feminine. These gender constructions are inextricably interwoven into both social structures (such as work, family) and the distribution of privileges, resources, and power.

Whereas gender is a social status that organizes many aspects of relational and familial life, it is also enacted continuously in interpersonal relationships (often described as “doing gender”). Such a conceptualization of the ongoing construction and performance of gender sharply contrasts with biological notions of gender (which place gender into the realm of the natural, inextricably linked with anatomical sex), and *gender-role* perspectives (which emphasize gender as a social role that is marked by a well-articulated set of behaviors and attitudes that through socialization become integral to one's self-conception). Such biological and role perspectives emphasize *gender difference* and may overemphasize differences between men and women. Research on whether and to what degree men and women evidence divergent patterns of interpersonal communication (e.g., men use more interruption, self-display, and assertion; women are more relational in their speech and attuned to nonverbal cues) is a case in point here, to the extent that the

researcher either states or implies a biological basis for the differences, or treats the differences as so inherent to men versus women as to naturalize them. Feminist researchers on the other hand, seek to deconstruct the observation of gendered patterns of communication by examining how these patterns are constituted in the first place, how they play out in interpersonal interactions, and how they reflect and reinforce the structural inequities of men's and women's lives. Feminist perspectives further emphasize how individuals subvert and remake such gender constructions and seek to understand how both exaggerating and obscuring gender differences are constructions in and of themselves.

Feminist scholars also deconstruct sex and sexuality, with an emphasis on challenging binaries to understand the diversity of sexual identities, orientations, and practices. Here, the binary construction of heterosexuality as "normal" and other sexualities as deviant or pathological is critiqued, as are ways in which sex and sexuality are essentialized and inextricably linked with gender. Feminist analyses have given visibility to the ways in which heterosexuality, masculinity, femininity, and family ideology are so tightly intertwined and coconstructed as to make them nearly impossible to conceptualize separately. Thus, feminist theorists also contest *heteronormativity* (the ways in which heterosexual models of relationships are assumed to be so normal and natural that they go unquestioned and unrecognized).

Intersectionality

Intersectionality emphasizes the ways in which the interplay of social locations (such as race, class, gender, sexuality, nation) influences the identities, privileges, and oppressions of individuals and families. For example, racism, sexism, and their unique and multiplicative confluence shape both the stereotypes of Black women's intimate relationships and the choices Black women have in responding to relationship stressors. An emphasis on intersectionality stems from the work of multicultural and critical race feminists, who challenge conceptualizations of the experience of White, Western, heterosexual women as

universal and monolithic, and instead situate difference and identity across the fluid intersections of multiple social locations. Intersectional perspectives call for an examination of the ways in which multiple forms of oppression (including heterosexism, racism, class privilege) are cocreated with sexism. Scholars using intersectional perspectives also deconstruct and look for variation within social locations, for example, examining variation in sexual expression that goes beyond categories of heterosexual, gay, or bisexual or looking for the wide variety of cultural expressions and histories that are present within a group of Latinas. Feminist standpoint theorists in particular examine how the "politics of location" are negotiated and experienced and emphasize the ways in which multiple intersecting identities mutually contribute to identities and experiences.

Attention to Power

Feminist researchers seek to articulate the power processes that are embedded within (and support) gendered constructions of relationships, families, and institutions by highlighting the ways that men and women are granted differential access to material, symbolic, and social resources. These structural inequities play out in a variety of ways, not the least of which are the construction of inequality as an inevitable outcome of natural gender differences, and the devaluation of women's work at home and in the paid labor force. In taking a feminist perspective on relationships, the interplay of institutional or structural power and interpersonal power is emphasized. For example, feminist research on wife battering highlights how institutionalized privileges have historically granted men the right to control women and children, how such domination plays out in the powerful interpersonal tactic of physical and psychological aggression, and how a woman's responses to the battering she experiences are constrained by social institutions and economic realities. Power processes are not always so overt; for example, power processes are often concealed within a romanticized discourse of equality that masks male domination of relationships.

Situating Relationships and Families Within Sociohistorical Contexts

Feminist perspectives on relationships push scholars to go beyond the individual and relational levels to consider the interplay of larger sociohistorical contexts. Feminist researchers question the notion of “the family as a haven in a heartless world”; rather, the family is viewed as a key institutional structure that has contributed to women’s subordination and oppression. Heterosexual romantic relationships and families in the United States are undergirded by a history that includes the isolation of the nuclear family, romantic heterosexual love as the basis for legal marriage, separate spheres for men and women, and differential access to economic resources. Although relationships and families experienced fundamental changes during the 20th century, particularly in beliefs and practices around egalitarianism, feminist researchers have analyzed the ways in which ideologies and discourses about ideal romantic, parental, and family relationships still are deeply intertwined with the gendered division of household labor and the allocation of time between work and family. Ultimately, feminist scholars emphasize the problems inherent in an exclusive focus on characteristics of individuals or relational processes and call for attention to the historical, economic, and structural roots of gendered practices and beliefs that contextualize and fundamentally influence intimate relationships.

Rejection of Unitary and Idealized Notions of Families and Relationships

Feminist scholars challenge both the idea of a universal heteronormative family (i.e., male-headed, heterosexual, lifelong, existing across time and culture) as well as the notion that the biological nuclear family should be the ideal against which all other family forms are judged. Instead, families and relationships are viewed as socially constructed and historically bounded; emphasis is placed on families and relationships as changing over time and place in structure and meaning. Marriage is viewed as a special category of intimate relationships—one that hinges on and elevates gender difference (given that the family is the primary arena where

gender is constructed). The tensions and contradictions of intimate relationships are examined; for example, feminist scholars have noted a “paradox of love and violence” that occurs when violence is perpetrated by a family member who also professes love for the victim. Feminist perspectives also emphasize that while the family is a site of women’s subordination, women are still active agents in their family and intimate lives—they creatively resist and subvert gender/family constructions and use their strengths to negotiate around and through constraints and oppression.

Feminist perspectives embrace the diversity of families, relationships, and people, looking at the intersections of gender, race, ethnicity, class, age, sexual preference, ability, and nation. Feminists also critique the ways in which the privileging of heteronormative, White, middle-class family forms have affected research on families of color, lesbian/gay families, poor families, and so forth. Feminist scholars bring variation and diversity in intimate relationships to the forefront, examining, for example, the multiple and diverse household formations that effectively nurture children, the strengths and stressors experienced by lesbian parents and their children, the strong kin and community ties of Black couples, and the experiences of noncustodial mothers.

Feminist Methodologies

Feminist relationship and family scholars use research methodologies that are recovering, reflexive, critical, and politicized. Feminist methodologies analyze gendered epistemologies, working both to recover women’s voices and experiences and to challenge the disciplines by rethinking theories, concepts, assumptions, and methods. Feminist critiques include analysis of what “counts” as knowledge in the academy, whose knowledge production is privileged, and the hierarchy of methods, theories, and data collection techniques that ascribes higher value to particular research approaches. Feminist methodologies openly acknowledge that all research is historically, culturally, and politically bounded (even positivist, objective, “scientific” research). Reflexivity in research requires

conscious reflection about how the researcher comes into and enacts the research, including analysis of one's subjectivity, relationship with research participants, and questioning of the researcher as the ultimate "knower." Feminist methodologies also emphasize the importance of maintaining a dialectic between theory and practice and the inherently political nature of scholarship that aims to critique and change social institutions, families, and relationships in fundamental ways.

FICTIVE KINSHIP

Fictive kinship comprises all those relationships socially understood as kinship different from descent and marriage, indicated by the usage of its terms, either modified (e.g., *comadre*) or not, as in some cases of fosterage, in which the term *mother* is the same regardless of whether it is the birth or foster mother. Taken literally, *fictive kinship* is a misnomer. As an antonym of *real*, *fictive* implicitly values such ties to be “false” or “not genuine” kinship. But people engaging in practices of fictive kinship experience these relationships as real as the ones based on “blood” and marriage, not least as they are also often tied to a prohibition of incest. After addressing the phenomenon in general, three aspects will be discussed in this entry that highlight the significance of kinship’s fictive forms for individuals, power processes, and theories of society.

Fictive kinship is found worldwide and covers highly diverse practices and experiences. Its most widespread forms are adoption (prominent in Oceania, in Western countries, and among South American Indians), sponsorship practiced in kinship such as godparenthood in Christian cultures (*compadrazgo*) or *oyabun-kobun* in Japan, fosterage (Central Africa, South America), blood brotherhood (Africa, North American Indians), more regionally specific types such as milk-kinship in Muslim societies or *miteri*-bonds in Nepal, and finally forms that are practiced without being named.

The differences between the documented forms of fictive kinship might be ascribed to the ways of its institutionalizations. Although people

commonly refer to rituals such as baptism to create a fictive kin relationship, in others people actualize it by continued reciprocal figurative use of kinship terms *and* actions that are understood socially as ideal kinship behavior. A figurative use of kin terms alone therefore does not institute a fictive kin relationship—it must be accompanied by concrete action. For example, people living together for a prolonged time with concomitant reciprocal use of kin terms may establish fictive kinship ties. Finally, all practices of fictive kinship are discernible as kinship only because people understand them as such. Further differentiating parameters lie in the quality of the relationship preceding the establishment of fictive kinship. Benjamin Paul devised an “intensive” and “extensive” choice of fictive kin for grasping analytically if individuals were related before (intensive) or not (extensive), and Sidney Mintz and Eric Wolf addressed the question of whether the people involved were of the same or a different social status with the respective terms *horizontal* or *vertical* relationships.

Three aspects of fictive kinship are central for its understanding and theoretical significance: connection, loyalty, and power. First, fictive kinship endows people with a social institution capable of bridging ethnic, religious, and class boundaries, therefore enabling individuals to establish or ascertain kin ties with social *others*. Fictive kinship, then, is singularly prominent in vertical relationships, especially in patron-client-ties that found their icon in Mario Puzo’s novel *The Godfather*. Albeit the institution of fictive kinship, conferring the egalitarian design of kinship ties upon vertical relations, never achieves an erasure of social inequality in practice, it allows humans to refer ideally to equality.

This widely documented social function leads to the second central aspect of fictive kinship: the institutionalization of a moral imperative of loyalty and solidarity within relationships. Fictive kinship establishes or heightens an affective relatedness, promising in turn an enduring relationship. Contrary to friendship, the relations of kinship are ideally irredeemable. The voluntary character of choosing fictive kin, in an intensive choice reenacting and assuring existing kin relations, explicates its social importance. When people endow their relationships with kinship’s moral imperatives of solidarity and loyalty, they signal a reciprocal will

to achieve a psychological maximum of security against internal discord.

Herein rests, thirdly, the theoretical significance of fictive kinship. It demonstrates as an actively sought transformation of relationship into kin ties that kinship in general offers the most efficient social technique to naturalize processes of power. The evident intentional character of fictive kinship substantiates the genuine social constitution of all kinship ties because these are sustained in practice only if individuals voluntarily actualize it by renewing its significance continuously. Even consanguineous kinship, that is, by “blood,” is meaningless in practice if individuals diverge socially, leading to a social exclusion of kin and potentially subsequent erasure from genealogical knowledge. The affective impact of the moral appeal of kinship ties, its characteristic imperative of solidarity and loyalty, is embodied through affects experienced early in life, habitus, and the culturally influenced socialization. Though relationships designed as kinship yield no guarantee of loyalty, ties practiced as kinship continuously render a security, even if self-suggestive, which cannot be attained otherwise.

As it is a culturally induced posture not to understand kin relationships as competitive or even as instrumental for one’s own power sake, they empower people, in particular when competitors or enemies are transformed into fictive kin. Although the intended continuation or intensification of kinship among social equals ideally suspends internal dissent, among unequals, it furthermore legitimizes exploitation and requires, at least partially, a participation in the power of the social superiors. These assigned qualities actualize the social and theoretical significance of kinship in general and of its fictive forms in particular.

But fictive kinship is still considerably underestimated in the social sciences. The field lacks both more detailed ethnographic investigation and theoretical synthesis of data. Perceived from a relational angle, fictive kinship critically influences societal arrangements. The fact that personal loyalty is not considered sufficiently in theories of class proves the necessity to advance the investigation of fictive kinship regarding psychological motives, relations of power, and society.

FIELD OF ELIGIBLES AND AVAILABLES

Humans seek relationship partners, and eventually mates, according to principles that help to narrow the universe of possibilities to a final choice. At least three general concepts are useful when thinking about how this winnowing process works: eligibles, availables, and desirables. Each of these may be thought of as a field or pool, a set of qualifying persons and, by implication, a residual set of others who do not qualify. This entry discusses each of these concepts in the context of the mating process.

The field of eligibles refers to socially acceptable categories of partners. This field has two types of boundaries. *Endogamous norms* specify eligible partners according to their membership in the same or similar groups. The most commonly operative endogamous criteria are social class, race, ethnicity, religion, and age. We are supposed to seek partners similar to ourselves in these respects because it is believed that such matches lead to more satisfactory relationships. The other eligibility criterion involves *exogamous norms*. Social expectations usually require or encourage us to seek partners who are different from ourselves

in certain respects. The two most common exogamous norms are that we should seek opposite-sex partners and partners who are not too closely related by blood to ourselves. Homosexual unions are legally prohibited in many but not all jurisdictions, and almost every society has rules that discourage or punish incest.

The field of availables refers to those potential partners whom we are likely to meet and with whom we therefore could develop a meaningful relationship. The two most common manifestations of availability are geographic proximity and not already being in a committed relationship. Proximity, sometimes known as propinquity, has obvious implications. We cannot become acquainted, let alone fall in love, with people if we have no chance of ever meeting them. Research shows that the closer two people reside geographically, the more likely they are to marry. So, proximity influences opportunities to meet. Marital status also influences availability. In societies that require monogamy, already being married makes you unavailable for a new romantic relationship. Despite the restrictions imposed by shared expectations about availability, it is easy to appreciate how these norms may be challenged. Advances in technology have made it possible to meet geographically remote people on the Internet. Extramarital affairs testify to the occasional disregard of marital status when dealing with rules about availability. The relative weakness of restrictions about availability has even led to the idea that everybody is permanently available to everybody else.

The field of desirables refers to those people who meet a set of personal preferences about possible partners. Among the most important factors here are physical attractiveness, personality characteristics, and leisure interests. Potential partners may have to meet certain standards of fashion, grooming, and beauty to be considered serious possibilities. They also may have to be sociable, pleasant, good listeners, and have a nice sense of humor. Desirable partners also may have to share several leisure interests in common with the person making the evaluation. Although preferences may appear to be unique to the person having them, many preferences are widely shared within a given culture. For example, standards of beauty may be influenced by the appearances and practices of

celebrities and the ways in which the mass media portray them.

When people apply ideas about fields of potential partners to a search for real partners, several practical considerations are involved. First, mate choice is interactive. For a couple or union to form, both partners must fall within their partner's acceptable fields. So, it is wise to be attentive to one's own appeal, not just to the appeal of potential partners. Second, the searching process occurs within competitive markets, so we have to display to potential partners some advantages over likely rivals. The size of the relevant fields of both rivals and potential partners shapes our chances of success. In addition, cultures differ in how inclusive or restrictive their fields of potential partners are. For example, first cousins are eligible mates in some cultures, but not in others.

Because most mate selection is heterosexual, the criteria that apply to defining appropriate males and females sometimes may be incongruent. For example, although males are generally taller than females, if few tall males are available, the normal expectations about height differences may be violated without objection. Finally, fields of potential partners depend on the purposes of the relationship. If we are dating just for fun, the field of acceptable partners may be much broader than if we are searching for a lifelong marriage partner.

We narrow our fields of potential partners in different ways. We may first eliminate ineligible, and then from among those available, search for desirables. Alternatively, we may concentrate entirely on those who are available, then determine desirables, and finally deal with eligibility. Whatever sequence the winnowing process may follow, our successive experiences of success and failure shape the way we approach our next opportunity.

FIRST IMPRESSIONS

Every interaction with a new person entails a first impression. The impressions we form of others and they of us influence practically every aspect of our lives, including our friendships, romantic relationships, and career prospects. Impression formation occurs rapidly, is often automatic and unconscious, and frequently occurs based on mere glimpses or instantaneous appraisals of “thin slices of behavior.” First impressions have important consequences in many different domains, including in the judgments of relationships, in job interviews, and in assessing others' personalities. And first impressions are critical because these original evaluations are often lasting, influential, and set the stage for subsequent expectations, behavior, and interactions. This entry first discusses the accuracy and downstream consequences of first impressions in the domains of relationships, deception, job interviews, and personality. This discussion is then followed by an examination of the characteristics of good judges of first impressions.

Thin Slices of Behavior

Thin slices of behavior was coined by Nalini Ambady and Robert Rosenthal to describe brief excerpts of expressive behavior sampled from the behavioral stream that contain dynamic information and are less than 5 minutes long. Thin slices are an excellent way to examine first impressions, and the slices can be sampled from any available

channel of communication, including the face, the body, speech, the voice, transcripts, or combinations of these. Hence, static images (e.g., photographs) and larger chunks of dynamic behaviors would not qualify as a thin slice.

The type of judgment being made affects accuracy. Thin-slice judgments are predictive and accurate only to the extent that relevant variables are observable from the thin slice sampled. Using the analogy of an onion, some characteristics, similar to the more visible, transparent outer layers of the onion, are easily observed and judged from thin slices. But other characteristics are hidden, similar to the inner layers of the onion, and are less easily judged from thin slices of behavior. Variables that are more observable and that are revealed through demeanor and behavior, such as extraversion, warmth, and likeability, are more easily and accurately judged from thin slices. In contrast, less observable variables, such as perseverance, are not easily or accurately judged from thin slices. This is because information regarding perseverance is more likely revealed through actions and behaviors that unfold over a relatively long period. Such information is less likely to be gleaned from thin slices of behavior.

Research on thin-slice judgments has had an impact across social, applied, and cognitive psychology and economics and has penetrated the popular literature as well. Thin-slice judgments are particularly useful in examining interpersonal relationships. For instance, judgments based on thin slices have been shown to accurately predict aspects of the doctor-patient relationship, including patient satisfaction and adherence to treatment, the relationship status of opposite-sex pairs interacting, judgments of rapport between two persons, and courtroom judges' expectations of a defendant's guilt.

Judging Relationships

Even nonhuman primates show an ability to quickly scan the social environment and recognize relationship patterns among others. These relationship patterns include those of kinship and status. During evolution, being able to make quick and accurate assessments of others' relationship patterns is important for survival of the species.

Among humans, do first impressions provide signals about different types of relationships? Evidence indicates that people can judge different types of relationships. For example, people (and animals) can judge kinship from minimal cues. They can also judge the status of individuals in an interaction, such as who is the boss and who is the subordinate, from first impressions. These accurate responses depend on a correct interpretation of available verbal and nonverbal cues. Thus, both kinship and status relationships are judged from cues such as posture and gaze. Finally, individuals can judge whether people are strangers, friends, or romantic partners based on minimal cues, such as posture, facial expression, and gaze.

In addition to identifying the type of relationship people share, perceivers also make inferences about the quality of relationships. One important characteristic of the quality of the relationships is the level of rapport between partners. Rapport is defined as the extent to which a relationship is pleasant, engaging, and harmonious. When two people feel rapport toward each other, they are more attentive to each other, more positive in their behavior to each other, and better coordinated in their movements. Can rapport be judged from first impressions? It turns out that people are not good at judging rapport or whether other people are "in sync" from observations of brief video clips. Thus, it seems that people are better at judging types of relationships than they are at judging the quality of relationships.

Another characteristic of the quality of a relationship is the love that exists between the partners. Studies relying on self-reports have found no differences in relationship quality between couples that reported falling in love at first sight and those whose relationships had evolved from friendships. Recent work on speed dating has yielded interesting insights regarding first impressions in romantic relationships. One important insight is that preferences for certain characteristics of an ideal partner expressed before speed dating do not predict the characteristics of the partner selected from the speed-dating event. Thus, predictions before the dating event do not line up with actual choices, suggesting that prior theories and beliefs do not accurately predict first impressions and liking.

How good are people at judging love between others based on their first impressions? People are

not good judges of the love between other couples from thin-slice video clips. Research has shown that people who were in love reported being more confident about their ability to judge whether other couples were in love but were actually less accurate than people not involved in romantic relationships. Thus, those in love may feel more confident about their ability to judge love, but are more biased than are those not in love. In sum, although perceivers have little difficulty categorizing the type of relationship that two people share, they are not as good at gauging the quality of that relationship, in terms of the rapport or the love between partners, from first impressions.

Deception

How well can deception be judged based on first impressions? Lying is ubiquitous in social life, and most lies are “white lies,” which are relatively harmless and are told to avoid friction and to maintain harmony in relationships. Other lies, however, are less innocuous, such as when liars maliciously manipulate individuals and organizations to advance their own self-interest.

Though people might lie quite often, they are not good at judging when others are lying. Meta-analyses of lie detection ability find average accuracy rate is 54 percent, only slightly better than that afforded by chance guessing.

One important moderator of accuracy in lie detection is the relationship between the liar and the detector. Research reveals that close friends show a substantial and significant improvement in lie detection accuracy (accuracy increased from 47 percent to 61 percent) over time as they get to know each other better, but less close friends show a small decrease in accuracy over time.

Factors such as expertise, experience, and formal training in lie detection do not seem to improve detection accuracy. “Professional lie catchers,” such as police officers, detectives, judges, secret service agents, and parole officers, are no more accurate at detecting deception than are students and other citizens. The one group of individuals that does seem to be more accurate at detecting lies than others is people with elevated levels of depression symptoms, who are better able to spot false reassurances and phoniness.

When perceivers do successfully distinguish truths and lies, they rely heavily on different streams of expressive behavior, including facial displays, gestures, and tones of voice. Are any of these channels particularly revealing of deception? The amount that people can control the information communicated by different channels of communication affects how revealing or “leaky” that channel of communication is considered. Verbal statements are believed to be the most controllable and therefore the least leaky channel of communication, followed, in order, by facial displays, gestures, and vocal tone. Vocal tone may be the leakiest channel of communication because the speaker’s perception differs from that of the listener. Because the voice sounds different to the speaker than to the listener, the speaker has difficulty monitoring and modulating it. Indeed, deception is most accurately detected from changes in the tone of voice compared with other channels of communication.

The bulk of research on deception detection comes from laboratory studies with undergraduate participants in which the liar’s motivation to be successful may be minimal. One meta-analysis of the literature examined whether the cues to deception become more transparent during “high-stakes” lies, when the liar has greater motivation to succeed. This analysis revealed that when liars are more highly motivated to succeed, they become tenser; specifically, they use less eye contact and use higher vocal pitch. This pattern is seen during real-life high-stakes situations, including murder, rape, and arson suspects undergoing police interrogations. Whether this greater transparency during higher stakes situations results in greater perceiver accuracy remains to be determined.

Job Interviews

First impressions are critical in job interviews, as documented in the plethora of books and articles on impression management in the job interview. Recent work suggests that interviewers’ early impressions affect interview outcomes. In general, studies have found that the more favorable the interviewers’ impressions on the preinterview measures are, the more positively they treat the applicant, and the more likely they are to extend

an offer to the applicant. Specifically, interviewers use a more positive vocal style with applicants who have made a positive first impression. Moreover, interviewers try to recruit the applicants who have made more positive first impressions by attempting to “sell” the company and the job to a greater extent and providing more information about the company than they do to applicants who have made less positive first impressions. Interviewer behavior also affects applicant communication style, and the more positive the interviewer, the more positive the applicant behavior. Thus, interviewers’ first impressions affect how they conduct the interview, and how interviewers conduct the interview is subsequently related to applicants’ behavior and their evaluation by the interviewer.

Personality

The ability to accurately gauge others’ personalities is also central to the development and maintenance of interpersonal relationships. How accurate are our first impressions of other’s personalities? The answer depends on the personality trait that is being judged.

In a pioneering study in 1938, Stanley Estes compared perceivers’ impressions of personality with targets’ self-reported assessments. After viewing two-minute film clips of people engaged in expressive movement, perceivers were able to judge emotionality, inhibition, and apathy at levels above chance. Half a century later, other researchers have examined the accuracy of perceptions of the Big Five personality traits (Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness to experience) from first impressions based on brief encounters as well as on videotapes and thin slices. Judgments of extraversion and conscientiousness show the highest correspondence with self-assessments, but neuroticism, agreeableness, and openness were less well judged. Even when targets’ romantic partners or family members are asked to describe targets’ personality, extraversion and conscientiousness emerge as the most accurately judged traits from first impressions.

Another line of research has shown considerable agreement or consensus regarding personality traits of complete strangers. Several studies suggest

that unacquainted judges exhibit a surprisingly high degree of consensus in their impressions of a stranger’s personality. Although consensus increases with increased exposure, independent perceivers still agree in their assessments of a target’s personality even in the absence of interaction with that target. Consensus is again particularly strong on two personality traits: extraversion and conscientiousness.

Perceivers can be surprisingly accurate in their impressions even without the benefit of direct interaction. Impressions formed after brief observations lasting a mere 10 seconds are as accurate as those based on 5-minute observations, indicating that personality is often revealed in thin slices of expressive behavior. Moreover, a surprising amount of information about personality is revealed in the environments we construct—whether real or virtual. For instance, first impressions of individuals’ personalities based on their bedrooms or offices have been shown to correlate with their self-reports as well as with close acquaintances’ ratings of the target person’s personality.

Individual Differences: The Good Judge of First Impressions

What are the characteristics of good judges of first impressions? Several factors affect individual differences in the accuracy of first impressions of relationships, including differences in personality and motivation. For instance, individuals who are more highly motivated to understand others and who have greater social skill and competence are more accurate in their first impressions. Conversely, people who are self-preoccupied perform poorly. Knowledge about social relations is also an important moderator. People who have had advanced theatrical training score higher on some tasks that measure the accuracy of first impressions. This could be because their theatrical training sensitizes them to the meaning of particular gestures, facial displays, and vocal patterns.

Women tend to be more accurate judges of first impressions and nonverbal behavior than men do. This female advantage may be the result of socialization and societal expectations. Women may have more knowledge of nonverbal cue meanings and may be more sensitive to such cues.

Increasing evidence also indicates that the most accurate judges of first impressions are people who are socially well adjusted. Certain groups of people with clinical disorders such as autism, schizophrenia, mania, and alcoholism are particularly impaired in their ability to form accurate first impressions.

Even though, overall, both children and adults who enjoy greater interpersonal success are generally better judges of first impressions, individual differences are tempered by cultural and subcultural exposure. For example, people are better at accurately judging targets from their own culture and cultures similar to their own than with more foreign targets.

Self-Fulfilling Prophecies in Interpersonal Relationships

Both accurate and inaccurate first impressions may affect the perceiver's subsequent behavior toward the target as revealed in the studies on job interviews discussed. Perceiver behavior shapes and constrains targets' responses, creating self-fulfilling prophecies (also termed *interpersonal expectancy effects* or *behavioral confirmation*). A self-fulfilling prophecy is an originally false definition of the situation that evokes behaviors making the false conception come true. Empirical research on interpersonal self-fulfilling prophecies emerged from Robert Rosenthal's influential work showing that experimenters' expectations can unwittingly bias the results of their experiments with both human and animal participants. For instance, in one study, the rats of experimenters who were led to believe that their rats were good at running mazes, ran the maze faster than did the rats of experimenters who were led to believe that their rats were not good at running mazes. The false expectations of the experimenter thus evoked behavior from their animal subjects that validated the expectations, creating a self-fulfilling prophecy.

Rosenthal and his colleagues later documented this phenomenon in other interpersonal domains, including the classroom. They showed that the expectations of teachers affected the intellectual performance of students. Teachers were told at the beginning of the year that some students in their

class (selected randomly by the experimenters) were going to be "late bloomers" and show gains in intellectual competence in the next few months of school. At the end of the year, those students showed higher intellectual test performance scores than did children in the control group, indicating that teachers' expectations affected student performance. Although the idea that experimenters' and teachers' expectations could create self-fulfilling prophecies was initially met with considerable resistance, eventually enough replications were published to quell most critics. Meta-analyses of the literature on expectancy effects have subsequently shown that these effects are statistically significant and accompanied by a mean effect size that is moderate in magnitude.

Self-fulfilling prophecies have consequential effects on many different types of interpersonal relationships. In one study, for instance, male participants were given a description sheet of a female with a photograph of either an attractive or unattractive woman and were told that they were going to have a telephone conversation with her. After seeing the photograph but before conversing, men expected attractive women to embody more positive traits. After conversing with a female confederate, men's impressions remained consistent with their initial expectations: Women believed to be attractive were rated more positively, whereas women believed to be unattractive were rated more negatively. Interestingly, independent coders who were unaware of which photograph the men had seen rated the audiotaped conversations of the women who had randomly been paired with the attractive photos more positively. Further analyses of the audiotapes showed that male participants treated partners whom they believed to be less attractive in a less warm, sociable manner, thereby eliciting a more negative reaction from these women than from partners whom the men believed were more attractive. Thus, interpersonal expectations, even over a brief telephone conversation, created a self-fulfilling prophecy that resulted in female participants behaving in ways consistent with their male partners' initial appearance-based expectations. Similar results have been found in other behavioral confirmation studies that have manipulated impressions or expectancies regarding a variety of target traits, including personality, race, hyperactivity, and mental illness.

Thus, both accurate and inaccurate first impressions lay the foundation for subsequent behavior. First impressions are critical in the formation of fundamental social relationships and influence both whether a relationship is established and the quality of the relationship once it is established.

FLIRTING

What do peacocks displaying their plumes, strutting chimpanzees, and smiling women in bars have in common? Chances are they are engaged in flirting. Birds, nonhuman animals, and humans all engage in behavior designed to attract potential mates. These primarily nonverbal behaviors are designed to show off the individual's desirable traits (large, colorful plumes, big chest, or bright teeth, respectively), attract attention, and signal that one is open to "approach." Scientists who study animal behavior, or ethology, have long studied how animals signal their interest and availability to potential mates. More recently, social scientists have begun to explore how humans do the same. This entry explores why humans flirt, how men and women flirt in cross-sex relationships, and why women and men may differ in their interpretations of flirting behaviors.

Why Do We Flirt?

From an evolutionary viewpoint, one of the most important task humans (and other animals) must accomplish is to locate a mate with whom they can reproduce. If humans fail at this most basic of duties, the species ceases to exist. To some extent, then, we are hardwired to flirt. It helps us attract the attention of potential mating partners. But why do happily married and committed individuals flirt with the mail carrier or the waitperson at the local café? They do so because flirting serves a variety of other purposes as well. Flirting validates others' sexual appeal, which provides enjoyment and enhances self-esteem; thus, flirting can increase liking and act as a "social lubricant" that makes interaction smoother and more successful.

Basic biological differences, however, have influenced men and women to develop different roles in the mate selection process. Because women can become pregnant and must devote years to any

offspring produced, they have greater investment in being selective. Men, however, benefit from being less selective in that doing so increases their chances of mating and producing offspring while incurring relatively low costs. Therefore, women tend to control the early stages of mate selection by choosing desirable males to whom they signal their availability, often through flirting.

Verbal and Nonverbal Flirting Behaviors

Women initiate flirting by targeting males to whom they signal their interest nonverbally—often by displaying the “coy glance.” The *coy glance* refers to a sequence in which a woman begins by looking at a male and offering a quick smile, then drops and turns her head as she offers a sidelong glance. This is a flirting signal that Irenäus Eibl-Eibesfeldt, founder of the field of human ethology, documented in cultures around the world. Other nonverbal signals of interest women use are the “head cant,” where the neck or the nape of the neck is exposed; the “skirt hike,” in which the legs are crossed so more of the leg is revealed; and the “forward body lean,” which signals interest as well as emphasizes the bosom and narrows the waist. Perhaps the most commonly enacted nonverbal flirting cue used by women is the hair flip—where a woman tosses her hair over her shoulder or uses her hands to move it about to draw attention. These behaviors occur frequently because they signal that one is open to being approached, and because they highlight physical attributes that reveal one is attractive, healthy, and sexually fit as a potential mating partner.

Men also flirt nonverbally, though not to as great an extent. In courtship settings, such as bars and parties, men often display an open body stance. That is, they stand so that the chest is expanded and hands are placed on the waist—which emphasizes the triangular body shape preferred in men. This posture also suggests he is unthreatening and approachable. Men, as well as women, use prolonged eye gaze to signal interest and capture the attention of a desirable other. Finally, both men and women perform the “eyebrow flash,” which describes the tendency for individuals to raise their eyebrows (usually unconsciously) when they find someone to be attractive.

Not all flirting occurs nonverbally. Both men and women use verbal strategies to entice and attract each other. Men are more likely to approach women to initiate a verbal interaction; thus, men are better known for using “pick-up lines” or utterances designed to foster conversation. Although the best pick-up line seems to involve simply saying hello, men also use innocuous statements such as “Do you know the time?” A few brave (or perhaps brazen) souls may attempt to use funny-cute lines, such as “If I told you that you had a beautiful body, would you hold it against me?” However, funny-cute lines tend to be evaluated negatively by women, who report preferring direct or innocuous opening lines.

Once interaction is initiated, both men and women use conversational strategies to engage one another. They may ask questions designed to give others a chance to talk about their strong points and that can serve simultaneously as a compliment. For example, one might ask, “Do you work out a lot?” Other conversational strategies used to signal interest are empathizing, mentioning an upcoming activity, and asking for or giving one’s phone number.

Sex Differences in Interpreting Flirting Behaviors

Although both men and women are active during the flirting process, they don’t always agree on what the behaviors mean. Men are more likely than women to say that women’s flirting behaviors reveal sexual interest, but women more often state that they are being friendly. This difference in interpretation occurs for two reasons. First, as discussed, men run fewer risks from mating and are the ones who approach a potential partner; therefore, they increase their chances of successfully mating if they interpret a broader range of behaviors as signaling sexual interest. In addition, flirting behaviors are deniable by design. That is, flirting behaviors are subtle and ambiguous enough that one can deny one was flirting at all. If faced with rejection or the angry partner of one’s target, an individual accused of flirting can save face (and possibly body) by arguing that he or she was just being friendly or was simply acting socially engaged and pleasant.

Flirting serves an important role in relationship development, and those who are competent at it increase the pool of candidates from which they can select a partner. However, men and women need to be aware that they may not agree on what, exactly, constitutes flirting.

FOOD AND RELATIONSHIPS

We spend a large portion of our time preparing for, thinking about, planning, and consuming our meals. Food is more than an essential component of physical survival. Along the course of evolutionary history, we have developed rituals and culture around food to make it a social experience. There is a reciprocal connection between the food we eat and the relationships we have, affecting us as a society, as a family, and individually. Food can affect our social relationships just as social relationships can affect our food consumption. This entry reviews the current literature and discusses the ways in which food and relationships intertwine.

Food and the Evolution of Society

In our early evolutionary history, food was scarce, and great efforts were made just to obtain foodstuffs to eat. During this time, sharing food became a valued strategy to gain access to more resources, aide survival, or increase mating

opportunities. Societies used four major strategies of food sharing, sometimes in combination with one another, to gain access to these benefits.

The *kinship model* (or kin selection-based nepotism) describes food sharing between kin; it predicts that food sharing should be more prevalent among individuals who are closer in genealogical relatedness. Consistent with evolutionary theory, kinship food sharing is thought to increase gene survival and reproductive success of offspring and related family members. In most societies, food sharing is more prevalent among family members than strangers, especially for younger and older kin who cannot provide for themselves.

The *costly signaling* model holds that food is used as a status symbol and mating strategy. Men with the biggest food production or displays of bravery during a hunt are revered in their communities and prove that they can provide for their women and families. In addition to providing nutrients, food sharing is a way to display power and gain a selective mating advantage.

According to the *reciprocal altruism* model, sharing food is an important way to keep food on the table during times of scarceness and allows for gestures of goodwill between families and tribes. Showing goodwill and a desire to work with other groups establishes mutually reciprocal relationships, in which each group consistently helps the other. This model describes an ongoing equal trade between groups, using such commodities as money or other traded goods. By creating trustworthy relationships, food is used to build bridges between different groups.

A final model of food transfer is described as *tolerated scrounging*, in which individuals give up their food to another person without expectation of return. This can encompass making donations to a beggar or giving up food to a thief. Generally, transfers of this kind occur when the cost of protecting the food is less than the benefit of giving it up.

Demographic Influences of Food Preferences

Food choices are associated with family-related demographics. For example, in genetic studies, twins show similarities in ratings of hunger, the amount of food eaten, and liking of foods beyond what can be explained by the environment. In the

nature–nurture debate, our relatives have some impact on the way we perceive and consume food.

Family culture also plays a part in food preferences. For example, Puerto Ricans eat more fried foods and sauces compared with Hondurans, and Northern Chinese people prefer wheat-based products such as dumplings to rice, which is preferred by Southern Chinese people. In certain cultures, a plump figure is seen as healthy, and slenderness is seen as frailty. Cultural influences determine what parents and children eat and often their attitudes toward food.

Food choices of parents are also related to socioeconomic variables of education and income. Higher education is often associated with healthier food choices, such as higher fruit and vegetable consumption. Having parents who are well educated about nutritional choices helps children model the same behaviors. In addition, it increases the chances that those healthier foods are available in the household. Those with higher income can also afford to be more selective about the foods they eat, buy more nutritional foods even if they are already prepared, or hire help to run the household and cook.

Food and Family Dynamics

Food has been associated with relationships starting from infancy with mother-to-child feedings. During infant feedings, skin-to-skin contact and mutual gazing is thought to promote emotional bonding between the pair. *Oxytocin*, a mammalian hormone, is released during labor and when nipples are stimulated. The release of this chemical during breastfeeding is associated with lower heart rate and lowered anxiety in the mother enhancing the tendency to bond with the infant. The bonding in turn helps with infant survival by promoting mothers to stay close to their child.

As infants grow, mealtime often becomes a family ritual. Mealtimes help us socialize about food and food-related rules. Routines at mealtimes teach children about the way in which meals are consumed, how food is served, how to leave a dinner table, how and when to eat snacks, permissibility of wasting food, and how much and what kinds of food to eat. Parents, grandparents, caretakers,

and peers guide learning of these habits that are developed at an early age and persist through adulthood.

Food consumption is also influenced by rewards and punishments, verbally as parents communicate the distinction between what is okay and not okay, and also physically when food is used to reward—if you finish your vegetables or get straight A's, then you get ice cream. Rewarding and punishing experiences can help people associate emotions with foods, although they may lead to emotional eating; for example, eating sweets to make yourself feel better. While positive relationships with food can create healthy eating habits, criticism, inappropriate rewards, and misinformation can lead to disordered eating and other negative eating habits.

Besides being just an educational opportunity, mealtimes are also for individuals to come together and share an experience as a group. They provide opportunities to talk to one another and connect, discuss daily concerns and issues, give opinions, and have conflict. Even the ritual of having regular meals together can provide stability to a family, which is important in maintaining family cohesion and healthy eating, especially for daughters. In other words, nutritional quality is enhanced in more cohesive, functional family environments.

Changes in Family Mealtimes

Despite the benefits and social importance of mealtimes, recent studies, including landmark work by Robert Putnam, document the decline of family dinners. One explanation for the decreases in family mealtime is *time scarcity*—feeling like there isn't enough time. This effect is caused by the increase in responsibilities as family members work both inside and outside the home, an increase in productivity and longer work hours for some. Working more hours is especially true for those with less income, minorities, dual-income families, and single mothers. As a consequence of increasing demands both at home and at work, individuals experience less time to plan for, prepare, and consume meals.

Responsibility for food planning and preparation has been shifting in recent times, from being solely the woman's responsibility to being slightly

more egalitarian, with men and husbands taking on more household and food preparation responsibilities than in previous generations. As a consequence, couples and families are more involved in negotiating responsibilities of food planning.

Despite the added help, however, families still experience time constraints and feel that they have less time to prepare meals, which leads individuals to eat more outside of the house, many times consuming fastfoods. The availability of family restaurants and fast-food eateries makes dining convenient, but it often has the negative side effect of compromising nutritional quality and family mealtimes. Parents can see the exchange as a necessary compromise given their busy schedules and limited personal energy; however, this trade off is also often associated with guilt for not being able to provide the “right” kinds of foods and forgoing family bonding time.

Other Social Influences

Whether we know it or not, food consumption is also influenced by the people around us. One theory of *impression management* suggests that people restrict their food consumption to increase favorability in the eyes of others. Individuals who eat lightly are thought to show self-constraint, good manners, or femininity when eating. When paired with opposite-sex strangers, people decrease the amount of food they eat. When paired with people who eat sparingly, participants eat less than when paired with people who eat a lot. Food consumption is restricted when others are watching, despite one’s level of hunger, and this effect is especially exaggerated when the other person is not eating.

People generally restrict eating or match others in how much they eat to present themselves in a favorable light. However, *matching* occurs even when other people are not present in the room. If there is any chance that someone can evaluate them, people tend to look for cues from others, or cues left by others, to determine what is appropriate and eat similar amounts. Because eating can produce a self-conscious experience, when someone might be observing, restricted eating can decrease the time spent in such an uncomfortable state and may be the only way, in some cases, to make a favorable impression on an observer.

Most impression management and matching studies are conducted with strangers or in labs, where situations may be somewhat ambiguous. This may lead to more self-conscious eating and the need to take cues from others. In contrast to these previous findings, another major finding in the food consumption literature is that of *social facilitation*, which shows that we tend to eat more with others than we do when alone. This effect seems to be stronger when eating with familiar others, such as friends or family, than it does when eating with strangers. The effect is also generally stronger as the size of the group increases.

According to the *time-extension hypothesis*, time spent in the presence of food increases when others are present, so that increases the amount of food eaten. Alternatively, having a lot of people around may distract us from paying attention to our own food consumption, feelings of fullness, and the need to manage our impression.

Food as an Aphrodisiac

Whether used to enhance a sexual experience or to actually increase the libido, foods such as chocolate, oysters, ginseng, and strawberries have often been thought to boost one’s sexual appetite. To date, however, research has not supported the sexual effects of food on libido or sexual performance. Foods can produce physiologic effects—for example, spicy foods increasing heart rate, chocolate enhancing mood, and alcohol lowering inhibitions. Although foods may have some effect, their direct connection to sexual desire or performance has yet to be determined.

FORGIVENESS

Forgiveness is a response to being wronged that entails a change of heart in which anger, resentment, or indignation gives way to an attitude of goodwill toward the wrongdoer. Married persons view the capacity to seek and grant forgiveness as one of the most significant factors contributing to marital longevity and marital satisfaction, supporting Robert Quillen's widely cited observation, "A happy marriage is the union of two forgivers." In Western culture, forgiveness is thus considered critical in close relationships. The relevance of forgiveness for intimate relationships is further emphasized by the fact that our deepest affiliative needs are satisfied in close relationships and that partners in such relationships inevitably injure each other. Forgiveness provides a means of maintaining relatedness in the face of such injury. Recognition of this fact has led to an explosion of research on forgiveness in close relationships over the last decade.

Because it is a complex construct, considerable effort has been expended on conceptualizing forgiveness and how it might best be studied. Although a consensus has yet to emerge, central to various approaches to forgiveness is the idea of a freely chosen motivational transformation in which the desire to seek revenge and to avoid contact with the transgressor is overcome. It is generally agreed that forgiveness is an intentional process initiated by a deliberate decision to forgive. This position is consistent with philosophical writings that define forgiveness as the forswearing of resentment toward the wrongdoer. This entry reviews what is known about forgiveness and its effects on close relationships.

Forgiveness Distinguished From Related Constructs

The reference to effort by the forgiver embodied in the definition of forgiveness just outlined distinguishes forgiveness from related constructs such as forgetting (passive removal of the offense from consciousness; to forgive is more than not thinking about the offense), condoning (no longer viewing the act as a wrong and thereby removing need for forgiveness), and pardon (which can be granted only by a representative of society, such as a judge). Thus, the common phrase, "forgive and forget," is misleading, as forgiveness is only possible in the face of a remembered wrong.

In the relationship context, forgiveness needs to be distinguished from reconciliation. Although an inherently interpersonal construct, forgiveness occurs primarily within the individual. Interpersonal events, such as expressions of remorse by the wrongdoer, influence forgiveness, but the motivational change it embodies occurs largely within the individual. Reconciliation, in contrast, restores a relationship between persons and is a dyadic process that requires appropriate participation by both parties: It involves the restoration of violated trust and requires the goodwill of both partners. Forgiveness increases the likelihood of reconciliation but is not synonymous with it. There is no contradiction involved in forgiving a wrongdoer and ending one's relationship with the person. Reconciliation can occur without forgiveness, further emphasizing the need to distinguish between them.

Forgiveness also needs to be distinguished from accommodation. Accommodation involves responding to potentially destructive partner behavior by inhibiting the natural tendency to react in kind and instead reacting in a constructive manner. Potentially destructive partner behavior may take many forms but only when it represents a wrong is forgiveness relevant. Wrongs give rise to moral anger, a form of anger that occurs when a moral principle (an ought) is abrogated. In addition, accommodation might occur because potentially destructive partner behavior is construed in such a way that its destructive nature is ignored, overlooked, or downplayed or, when fully recognized, is condoned or excused. Under these circumstances, forgiveness is not a relevant concern. Although under certain conditions accommodation and forgiveness overlap,

accommodation is a much broader construct than forgiveness.

Who Benefits From Forgiveness?

Considering this question highlights a further characteristic of forgiveness. One view is that release from negative affect, cognition, and behavior toward the offender makes the forgiver the primary beneficiary. Because research on forgiveness has focused primarily on the forgiver, forgiveness has been viewed from this perspective. Most of what is known about forgiveness therefore rests on inferences made from the absence of a negative motivational orientation toward the transgressor. A second viewpoint emphasizes the offender as the primary beneficiary because he or she receives an undeserved gift and is released from an obligation. This perspective tends to emphasize the positive dimension of forgiveness. At the empirical level, there is evidence of at least two underlying dimensions of forgiveness, a negative dimension and a positive or benevolence dimension. However, there is less agreement among researchers about whether forgiveness requires a benevolent or positive response (e.g., compassion, empathy, affection, approach behavior) to the offender or whether the absence of negative responses (e.g., hostility, anger, avoidance) is sufficient.

The negative dimension, known as unforgiveness, sometimes yields two sub-dimensions, retaliation directed at the partner and partner avoidance. In the context of close relationships, change regarding both positive and negative dimensions of forgiveness is necessary. It is difficult to imagine an optimal relational outcome without forgiveness restoring real goodwill toward the offending partner. Given ongoing interaction between intimates, the nature of the relationship (e.g., closeness, quality) was a natural starting point for the study of forgiveness in relationships.

Forgiveness Is Related to Central Relationship Characteristics

A number of studies have shown that forgiveness is robustly and positively related to core relationship constructs, specifically commitment, closeness, and

relationship satisfaction. In addition, forgiveness is positively associated with the ability to effectively resolve relationship conflict. Although important, the documentation of such associations raises questions about the direction of effects. It can be argued that following a relational transgression, forgiveness has to occur before damaged closeness and commitment can be restored: It is difficult for the hurt individual to feel close to his or her offending partner if he or she still harbors a grudge about the transgression. Conversely, it also has been argued that the forgiveness-commitment association is driven by commitment because highly committed individuals may be more motivated to forgive simply because they intend to remain in their current relationship. Consistent with this viewpoint is some experimental data suggesting that greater commitment facilitates interpersonal forgiveness. However, manipulation of constructs such as commitment and forgiveness raises practical and ethical difficulties making experimental research difficult. Recognition that psychological changes in forgiveness, closeness, and commitment following an interpersonal transgression necessarily have a temporal component points to longitudinal research as a potential means of determining direction of effects.

Longitudinal evidence indicates that forgiveness promotes increases in commitment, whether forgiveness is assessed in terms of decreased retaliation, decreased partner avoidance, or increased benevolence toward the partner. Limited evidence also shows effects from commitment to forgiveness in that greater commitment predicts decreases in partner avoidance. Regarding relationship satisfaction, the picture that emerges also supports bidirectional effects. For example, a spouse's marital satisfaction predicts his or her forgiveness 12 months later and vice versa. In a similar vein, husband marital quality predicts later wife forgiveness whereas wife forgiveness predicts husband's later marital satisfaction.

Relationship satisfaction also influences documented differences between victim and perpetrator perspectives of transgressions, which may explain why forgiveness and satisfaction are related. Specifically, victims tend to overlook details that facilitate forgiving and embellish their memories with details that make forgiving more difficult, whereas transgressors tend to embellish details, such as extenuating circumstances, that facilitate

forgiving. However, individuals in highly satisfying relationships are less likely to exhibit these self-serving biases than are individuals in less satisfying relationships. Existing data are consistent with a causal sequence in which positive relationship quality leads to more benign interpretations of a transgression, which in turn promote forgiveness. Relationship satisfaction may therefore help meet the challenge forgiveness poses whereby the victimized partner has to cancel a debt that is often perceived as bigger than the debt acknowledged by the transgressing partner.

More Than an Artifact?

The robust association between forgiveness and relationship satisfaction raises an important challenge. Because forgiveness is conceptualized and measured at the intrapersonal level, data pertaining to it rely exclusively on self-reports. It is thus possible that forgiveness serves merely as a proxy for relationship satisfaction. Research on marriage is replete with constructs and measures that unknowingly tap into the same domain. As a result, the marital literature is strewn with an unknown number of tautological findings resulting from content overlap in the operations used to assess purportedly different constructs. Is the study of forgiveness in relationships simply the latest instance of this phenomenon?

A few studies have addressed this challenge by statistically controlling relationship satisfaction scores when examining forgiveness and its correlates. This work suggests that forgiveness is not simply relationship satisfaction by another name. For example, a well documented correlate of relationship satisfaction is conflict behavior. Forgiveness accounts for variability in concurrent conflict resolution beyond that which can be attributed to the relationship satisfaction of the partners in the relationship. Moreover, over a 12-month period, wives' self-reported benevolence predicts husbands' reports of conflict resolution independently of each spouse's satisfaction and wives' reports of conflict resolution.

More Than a Trait?

Perhaps forgiveness in close relationships simply reflects the partners' traits. This seems like a

reasonable hypothesis given the finding that a substantial portion of the variability in willingness to forgive a transgression (between 22 percent and 44 percent) is attributable to stable individual differences in the tendency to forgive. This hypothesis embodies two notions, that forgiveness reflects a stable tendency of the forgiver, their dispositional forgivingness, or the forgivability of the offending partner. But there is also a third possibility in that forgiveness may reflect relationship-specific factors. When these possibilities were examined, reactions to spouse transgressions were found to be determined largely by relationship-specific factors rather than by individual characteristics of the forgiving spouse or the offending partner.

More Than an Act?

There is the temptation to identify forgiving with a specific statement of forgiveness or an overt act of forgiveness. However, the verb form *to forgive* is not performative but instead signals that a decision to forgive has occurred. The statement by itself does not constitute forgiveness but sets in motion a process with a presumed endpoint that unfolds over time.

This creates particular challenges in a relationship. Although the words "I forgive you" may signal the beginning of a process for the speaker (of trying to forgive the transgression), they tend to be seen as the end of the matter by the offending partner who is likely to be only too willing to put the transgression in the past and act as if it never happened. The offending partner may therefore be puzzled, annoyed, or angry when incompletely resolved feelings of resentment about the harm-doing intrude on subsequent discourse or behavior in the relationship.

The potential for misunderstanding also occurs when communications regarding forgiveness are poorly executed. The partner may see even forgiveness that is offered in a genuine manner as a put down, a form of retaliation, or a humiliation if it is unskillfully executed. Finally, statements of forgiveness may be intentionally abused. They can be used strategically to convey contempt, engage in one-upping, and the like. Likewise, verbal statements of forgiveness may not reflect true feelings. Such statements of forgiveness without accompanying internal changes have been labeled *hollow forgiveness*.

What Determines Forgiveness?

Researchers have repeatedly found that the more severe the transgression the harder it is to forgive. Forgiveness can be observed in exchanges between the offender and the victim, and how these exchanges unfold is likely to influence the forgiveness process. For example, it is well established that a sincere apology from the transgressor facilitates the forgiveness process.

Certain individual differences are related to forgiveness of relationship partners. Greater forgiveness is predicted by more agreeableness, conscientiousness, emotional stability, and extraversion and higher self-esteem and need for approval. However, as noted earlier, relationship level factors are relatively more important in predicting forgiveness, and these include the factors mentioned thus far, as well as the tendency to repeat offenses and the degree of dependent and anxious attachment that exists between partners.

Benign attributions for the offending partner's behavior (e.g., "He was late for our date because the traffic was heavier than usual") are related to greater levels of forgiveness than are nonbenign or conflict-promoting attributions (e.g., "He was late for our date because he doesn't value our time together"). Among married couples, benign attributions predict forgiveness both directly and indirectly through lessening negative emotional reactions to the transgression and increasing empathy toward the transgressing spouse. Evidence also suggests that, compared with husbands, wives' attributions are more predictive of their forgiveness, a finding that is consistent with a larger body of evidence that supports a strong association between attributions and behavior among women. The robust association between attributions and forgiveness has led practitioners to pay explicit attention to attributions in interventions designed to facilitate forgiveness.

Finally, empathy plays an important role in the forgiveness process. Empathy has been shown to weaken motivations to avoid and seek revenge against the transgressor and to foster benevolent motivations regarding him or her. These motivational changes are assumed to occur because empathy causes the victim to resume caring for the transgressing partner on the basis of (a) the transgressor's imagined guilt or distress over his or her

behavior, (b) the transgressor's imagined longing for a restored relationship, or (c) a desire to repair the breached relationship. Empathy may also help restore the perceived overlap between one's own identity and the identity of the transgressing relationship partner. This perceived overlap might cause the victim to view forgiveness as being in his or her own best interests as well as in the best interests of the transgressor. However, the precise mechanism whereby empathy influences forgiveness remains unclear.

Can Forgiveness Be Taught?

Several interventions have been shown to increase forgiveness in romantic relationships, and various theoretical models of forgiveness have been used to develop these interventions. Most often, these are delivered in the context of psychoeducational groups or relationship enrichment interventions. An initial meta-analysis of 14 studies showed that there is a linear relationship between the length of an intervention and its efficacy: Clinically relevant interventions (defined as those of 6 or more hours duration) produced a change in forgiveness that is reliably different from zero, with nonclinically relevant interventions (defined as 1 or 2 hours duration) yielding a small but measurable change in forgiveness.

A more recent meta-analysis of 27 studies yielded a similar result and demonstrated that interventions were more effective in promoting forgiveness of partners than were attention placebo and no treatment control groups. In this analysis, however, intervention status predicted intervention effectiveness beyond the amount of time spent in the intervention. Most of the interventions included attention to helping couples understand what forgiveness is and is not (87 percent), encouraged them to recall the hurt (95 percent), and helped victims empathize with the offending partner (89 percent).

Although these findings demonstrate that we have made good progress in devising interventions to induce forgiveness, they refer only to self-reported forgiveness. This raises the question, "Does induced forgiveness produce positive individual or relationship outcomes?" Few studies address this question, and those that do have provided mixed results. This reflects, in part, the

fact that interventions tend to have been delivered to samples that are asymptomatic with regard to individual and relationship health. It is therefore noteworthy that participants screened for psychological distress before a forgiveness intervention showed improved mental health (less depression and anxiety) post intervention and at a 12-month follow-up. The analogous investigation to document impact on relationship outcomes remains to be conducted.

Cautionary Note

Research on forgiveness interventions and on forgiveness more generally has paid insufficient attention to an important element of the relationship context. Specifically, by focusing on forgiveness of isolated transgressions, patterns of offenses and forgiveness within a relationship have been overlooked. Given the rich history of transgressions that most couples experience, it is important to move beyond single offenses because each transgression is embedded in a complex relational story. For example, one cannot help a wife move toward forgiveness of her husband's onetime infidelity in the same manner that one would treat a couple in which the husband had a history of multiple transgressions of this kind. Thus, there is the need to consider how the pattern of transgressions over time influences the forgiveness of subsequent offenses within the relationship.

Conclusion

Recognition that forgiveness can be conceptualized and studied in secular terms has led to a marked increase of research on the topic, including its role in close relations. Forgiveness is related to core relationship constructs such as commitment and relationship satisfaction, though the mechanisms that account for the relationship are not yet fully understood. Evidence also indicates that psychoeducational interventions can facilitate forgiveness, but the impact of such interventions on individual and relational well-being remains to be determined. Promising findings from basic research on forgiveness in relationships suggests that facilitating forgiveness will prove to be salutary.

FOSTER CARE, RELATIONSHIPS IN

In 2005, Child Protective Services (CPS) found that almost 1 million children in the United States were substantiated victims of child abuse and neglect. Importantly, more than one third of these children were placed in foster care because they were at “imminent risk” for danger. Based on federal statistics, children enter foster care for several reasons: neglect (64.4 percent), physical abuse (9.1 percent), sexual abuse (3.3 percent), or multiple abuses (16.0 percent). Family-based foster care is the most common placement for children removed from their biological families, with 70 percent of

youth being placed in a nonrelative (46 percent) or kinship (24 percent) foster home. The average age of children entering care in the United States is 8.2 years old, and their mean length of stay is 28.6 months, although the range can vary from days to years. Half of those children entering foster care are expected to return to their biological parents.

Although practices vary, there is usually little preparation for children entering foster care. Children often move straight from their biological family into a foster home. The child and birth parent are given little or no information about the family with whom the child will live. The same is true for foster parents. They receive a call from a social services agency with vague details about a child needing placement. Further, foster families have a range of parenting experiences and may never have had a child in their home before. Most states have training for foster parents that addresses common issues, but little is known about the effectiveness of these programs for increasing knowledge of children's needs and development. Relationships, although theoretically central to foster care, often take a back seat to the pressing demands of the system. This entry explores the historical factors that affect the relational quality of children in foster care, as well as those they develop with their foster-care givers.

Psychosocial Adjustment of Children in Foster Care

Research on the many risk factors in foster care includes maltreatment, prenatal substance exposure, parental mental health problems, exposure to chronic poverty, and a disrupted and chaotic home life. The trauma of separation from biological parents as children enter foster care may be another risk factor for development. Individually, each of these risk factors is associated with a host of negative outcomes. Cumulatively, they put this group of children at high risk for poor outcomes, including those (e.g., unemployment and incarceration) that are costly to communities and to society in general.

Given these risks, it is not surprising that children in foster care have social and emotional problems at rates 3 to 10 times higher than the general population, as well as developmental delays,

physical problems, and difficulties in academic functioning that far surpass those of other children in the community. During adolescence and adulthood, studies show that children in foster care are at increased risk for substance abuse, depression, post-traumatic stress disorder, school failure, incarceration, and suicide. Although these findings appear bleak, the consequences of remaining in an abusive home are even more dire. Scientifically, it is hard to show that foster care has improved children's lives, although research is beginning that suggests children who are removed from their birth families do better socially, emotionally, and academically than do their siblings living at home.

Relationships and Risk Factors in Foster Care

By definition, children entering foster care have suffered a disruption in their relationship with their primary caregiver, as well as with friends, teachers, classmates, neighbors, and pets. Children move from an unsafe home into a home with strangers. Importantly, evidence suggests that in addition to the actual placement disrupting the parent-child relationship, many of the risk factors that bring a child into care are also those that have been independently linked to disturbed emotional ties with caregivers.

Maltreatment

Many of the risk factors associated with foster care are also correlated with relational disturbances. Most children enter foster care having experienced child abuse or neglect. Research is clear that maltreatment has an adverse effect on children's social, emotional, and cognitive development. Childhood maltreatment has been linked to aggression, depression, anxiety, attentional deficits, cognitive delays, and academic difficulties. In adulthood, a history of maltreatment predicts a host of psychological, social, and health problems, which may include heart troubles, alcoholism, and suicide.

Problems begin early in the lives of maltreated children. Young children show difficulties in their relationships with primary caregivers. Research indicates that without intervention, most maltreated infants will form maladaptive relationships with

their foster-care givers. This is because the history and problems that children arrive with often require specialized parenting skills. For example, Mary Dozier's research has shown that foster parents often respond to their children's responses "in kind"; that is, if the child does not seek attention, then the parents will not go out of their way to attend to the child. However, research suggests that foster infants can form secure attachments with their caretakers, but it is more likely to occur if the child is placed before 12 months of age and the foster-care givers exhibit their own history of an early secure attachment. More is known about the attachment of maltreated children who remain home. Recent research by Sheree Toth and associates indicates that almost 90 percent of infants with a substantiated CPS report who remained at home exhibited a disorganized attachment, which remained relatively stable over time. Disorganized attachment status in childhood has been linked to a range of psychological symptoms across the life span and is likely a factor in the reported increase in the incidence of attachment disorders in maltreated youth.

Parental Substance Abuse

Although no well-defined method exists for assessing substance abuse for biological parents of children in foster care, research indicates that it is common, with rates ranging from 43 percent to 79 percent. Substance abuse interacts with child well-being and relationships. The literature on children of substance-abusing caregivers highlights difficulties in development, including biological, emotional, and behavioral functioning. The link between parental substance use and child development is not simple, and multiple pathways have been demonstrated. Past research has identified direct links between parental substance use and the development of similar problems in offspring, especially for same-sex parent-child pairs. The child's early primary relationships provide an indirect link through caregiver mental illness, stress in the parent-child relationship, and deficits in parenting and parental monitoring.

Parental Psychopathology

Although only limited data are available for children in foster care, research on families involved

with CPS indicates that parental mental health needs are common. Results from the only national study of families involved with CPS indicate that 23 percent of caretakers whose children stayed in home reported symptoms indicative of a depressive disorder. In addition, estimates of other mental health disorders include 13 percent with psychotic disorders and 7 percent with other unspecified mental health disorders. This is important because maternal depression is related with reduced attachment security, less parental monitoring, and increased parenting stress.

Family Poverty

Children in foster care are exposed to maltreatment, parental substance abuse, and other trauma and live in some of the poorest U.S. homes. Family finance data for birth families of children in foster care are not available, but the income of 52 percent of families involved with CPS was at or below the federal poverty level. This compares with 11 percent of the general population who reported living at this level in the 2000 census. Financial findings for foster homes were significantly better, with 42 percent of nonrelative and 32 percent of kinship foster parents reporting incomes greater than 200 percent of the poverty level.

Poverty is a social condition, as well as a factor associated with negative effects on child development. Contextual influences such as adverse conditions in the home environment, poor quality of parenting, and parental physical and mental health problems appear to exacerbate neighborhood influences. One prevailing conceptualization maintains that poverty may affect children through the disruption of interpersonal relationships and interactions. As poverty alone adversely affects child outcomes, the added hazards associated with maltreatment and other risk factors are particularly pernicious.

Placement Disruptions

Moving from one foster home to another is common in foster care. One study of children's moves during foster care in California found that the average child moves 4.2 times in an 18-month period (the range was 1–15). Repeated movement is likely to have a profound effect on children's

relationships with caretakers—foster, biological, or other. Although relationship status has not been assessed as a function of moves, Rae Newton and associates found that moves often occurred in response to children's disruptive behavior, but that these behaviors escalated with each move. Thus, the transient nature of foster care appears to be yet another factor impairing the relational quality of its youngest consumers.

Relationships in Foster Care

Foster care was originally designed to provide "normal" homes for "normal" children. This initial assumption is inaccurate because research shows that the children who enter foster care actually show above average rates of psychological and behavioral problems. The formation of positive, healthy relationships between children and their foster parents is theoretically important because, as researchers have noted, there is no greater influence on children while they are in foster care than those who directly care for them. The foster family potentially provides a healthy context for children to solidify competencies, modify maladaptive behaviors, and develop new skills that may not have been modeled or taught in their biological homes.

Little research has focused on the qualities of foster parents that are related to optimal child outcomes. A review of available work indicates that parental nurturance, consistent limit-setting, and commitment to the child over time—regardless of whether they return to the birth home or not—are important to children's adjustment and functioning in foster care. In fact, commitment has been shown to be a better predictor of children's adjustment than attachment. This is most likely because commitment is transportable, but attachment, which develops over time and may be terminated after the child moves, is built on constancy and the level of security. In addition, a safe and stimulating home environment and a stable placement all contribute to positive outcomes for children in foster care. Examining the necessary ingredients for a quality foster relationship from the children's perspective is an area of study that is in its infancy. A recent study found that most children in care were satisfied with the people with whom they lived,

with high levels of relatedness and closeness to caregivers.

Although questions about relationships in foster care are not limited to attachment, this has generally been the focus of child welfare and mental health. The attachment status of children in foster care is important because these relationships affect interactions with the primary caregiver, as well as how youth will approach and react to later relationships with adults and intimate partners. Thus, early caregiving deficits, paired with repeated rejections and movements in the foster-care system make it less likely for children to form healthy, secure relationships in the future.

Although attachment interventions for children in care are rare, recent studies shed light on the benefits of improved relationships with foster parents. Dozier and colleagues' attachment intervention aims to train foster parents to better provide nurturing care to infants. Similarly, Phil Fisher and colleagues' preschool intervention targets developmental and social needs through a range of treatments. These programs both have been shown to produce increases in attachment security, but also a change in the children's biological systems. More specifically, past research on children in foster care show that they have significantly higher rates of cortisol abnormalities than do their nonmaltreated peers. Cortisol is an important hormone because it moderates the body's physical response to stress. The production of cortisol is especially important during infancy and early childhood because it is socially regulated and is highly vulnerable to disturbance in the absence of sensitive, nurturing caregiving. Cortisol dysregulation has long-term implications and has been linked to a range of symptoms, such as aggression, anxiety, and depression. The research provided by Fisher, Dozier, and others indicates that interventions can enhance attachment status while children are in foster care, and that the relationships developed in these programs benefit children across the broad range of functioning.

FRIENDSHIP, CONFLICT AND DISSOLUTION

Conflicts occur when friends seek incompatible goals or outcomes or they favor incompatible means to the same ends. To prevent interpersonal conflicts from adversely affecting their relationship, friends need to effectively manage these conflicts. Much of what has been written about conflict and relationship dissolution pertains to courtship, marriage, and family. This entry focuses on those aspects of interpersonal conflict and relationship dissolution that pertain specifically to friendship. Although there may be many causes of friendship dissolution, such as separation (moving away), change in social or financial status, marriage, or change in interests, this entry focuses on conflicts over relationship rules, which may destroy the relationship.

Rules of Friendship

From a rules perspective, people are faced with choices. As mutual expectations regarding what is appropriate in a given situation, rules generally

function as criteria for choice among alternatives. As constraints on the availability of choices, rules are guides to action. These constraints are normative in that when people know the rules, they tend to conform to them.

Data collected from a variety of countries show that the following six rules are generally endorsed as important for friendship:

1. Volunteering help in time of need.
2. Trusting and confiding in each other.
3. Showing verbal and nonverbal emotional support.
4. Communicating in ways that make him or her happy while in each other's company.
5. Speaking up for the other in his or her absence.
6. Sharing news of success with him or her.

This list is not meant to be all-inclusive but, rather, to suggest that identifiable rules define and govern friendships. If one views all but the second rule as indicative of a helping orientation and the second rule as the trust-confidentiality dimension, then helping orientation, trust, and confidentiality are important in defining friendship.

Identifying rules that are essential to a relationship more clearly distinguishes that specific relationship from other types. For example, friendship may be distinguished from romantic relationships, especially marriage. For many people, marriage involves its own rules such as agreeing to express a long-term commitment in a public ritual or wedding, to no longer play the field, to engage in sex, to share property, and to have and care for children. In the United States, spouses also expect one another to be good friends, so they usually share two relationships, a marriage and a friendship.

Friendship Conflicts

Like people in other types of relationships, friends may engage in many conflicts that do not involve relationship rules. For example, they may disagree about a political candidate, movie, or type of food. These disagreements usually do not threaten the friendship. However, disagreements about the rules of friendship may dissolve it.

Friendship rules become issues in interpersonal conflicts when one of the friends breaks one or more relationship rules, such as failing to help in time of need or lying to the other. Another way occurs when friends misunderstand the friendship rules and take too much advantage of others. The friendship rules are the issues in the conflict because the people involved have tacitly or overtly agreed on them, and now one person has violated or misunderstood one or more of the relationship rules.

Conflict and Dissolution

How does conflict regarding a friendship rule lead to relationship dissolution? Imagine that a person runs out of gas outside of town and calls someone she considers a good friend to come get her. Suppose the other responds with "Why call me? Why don't you call a taxi?" If one fails to help in time of need, the friendship is in trouble. The same logic holds for the friendship trust rule. As we develop friendships with others, we tend to develop a truth-bias toward them: We assume that they tell us the truth. So, lying to an acquaintance about why one does not want to go shopping is different than lying to a good friend because friends are supposed to trust each other. Violating the friendship rules of helping when needed and telling the truth become conflict issues because the two people involved have tacitly or overtly agreed to be friends, which means abiding by the rules governing the relationship, and now one person has broken "the agreement." Rules theory would predict that a friendship is in trouble when one of the partners violates the rules of friendship.

Although one might break a friendship rule, others might misunderstand their application and try to take too much advantage of friends who want to help them. Some people have acute emotional needs that can turn a friendship into a pseudo therapist-client relationship. This is different from a confidential type of friendship where friends listen to each other, give advice, and occasionally vent their anger. In more extreme cases, it is difficult for the average person to help a friend who constantly dwells on his or her own emotional problems and cannot change the subject for long without returning to and dwelling on it.

In other cases, a friend's needs may be too great a financial burden. Such a friend can present real problems because he or she constantly asks to borrow money, or when a friend accepts that person's checks, they bounce. Some may move in and live off their friends, contributing nothing financially. According to relationship rules, there are other types of interpersonal relationships, where one may expect to receive a greater degree of financial help than from friends, such as one's spouse, parents, and adult children. Friends may be expected to help one another, but a dependent person may demand too much. In this case, the problem consists of a single "behavior," such as asking to borrow constantly or only talking about one's personal emotional problems.

Other problems occur when the problem pertains to more than a single behavior. Many friendships are based on similar interests, usually involving a particular activity, such as people who play golf, bar hop, square dance, play cards, fish, or hunt together. These friends see themselves as companions. They can trust their companions to meet with them, play fair, and keep discussions about their activity among them. One does not expect a friend to tell "outsiders" that he or she is a bad golfer, drinks too much, or performs any questionable acts. These friendships may comfortably be limited to particular shared interests. However, if one tries to expand the limited basis for the friendship to other activities or attempts to develop a more confidential type of friendship, where they disclose at great depth, they may push the friendship beyond the limits of trust or other friendship rules. People need to be sensitive to their friends, work with them on maintaining a comfortable level of involvement, and not push them beyond their capabilities. This problem differs from misunderstanding the helping orientation rule discussed earlier in that it consists of more than one behavior. The other person depends too much on a friend in a variety of ways. For example, Ernesto enjoys fishing two to three times a week and meets Marty, who agrees to fish with Ernesto. The problem is that Marty also wants Ernesto to fish every day, wants him to accompany him on other activities during the rest of the day, and calls frequently just to talk. When Ernesto declines to meet more often or says he can't talk right then, Marty gets angry at Ernesto. The

problem is that Marty is demanding a broader range of activities and more time and effort from Ernesto than he can give to the friendship.

Friendship Repair Ritual

The previous cases call attention to common conflicts that may dissolve a friendship. However, if the offending person follows a “repair ritual,” she or he may be able to repair or preserve the friendship. Of course, at many of the steps of the ritual, one person could elect to terminate the relationship. The repair ritual has four steps:

1. *An offending situation:* A person believes that the other has acted in an inappropriate way.
2. *A reproach:* The offended person calls attention to the offense and asks the offending person for an explanation. However, the offended person may decide to end the friendship by avoiding the other person.
3. *A remedy:* The other person takes action to rectify matters. However, an offender may refuse to take such actions, which in all likelihood ends the friendship. Refusals include turning the reproach around and questioning the right of the offended person to make a reproach. If, however, the offender is willing to take responsibility for his or her actions, there are three types of actions an offender can take to restore the friendship: offer an account (through excuses or justifications), make a concession, offer an apology, or combine any of these.

Accounts are explanations for behavior when questioned. Accounts serve an important function in that they explain how people interpret the situation at hand. Accounts may take the form of excuses or justifications. These types of accounts are not always concocted but, rather, may be legitimate extenuating circumstances unknown to the person offended. In such cases, one may simply explain his or her side of the matter, without admitting guilt or apologizing. In other cases, it may be necessary to apologize. *Excuses* admit that the offense occurred but deny responsibility for it. The offender can claim impairment, diminished responsibility, or overriding problems of his or her own.

Justifications diminish the meaning of the offense rather than diffuse responsibility for it. Here, the offender acknowledges that an act was committed while maybe claiming that it hurt no one, the offended person deserved it, or the offender had good intentions when committing the offense. *Concessions* admit the offender’s guilt and include apologies and offers of restitution. When an excuse or justification is not acceptable, some concession must be made or an apology given. *Apologies* allow a person to take responsibility for an action, but they also request a pardon for the action by attempting to convince the offended person that the incident is not representative of what the offender is really like.

4. *An acknowledgment:* An evaluation of the account is supplied by the one offended. The offended party may honor the account, signaling that the “score is even.” The offended party may retreat from the reproach, dropping his or her right to make it. The offended party may also simply drop or switch the topic, moving away from the reproach without resolving the issue. Most problematic for the friendship is a *rejection of the account*, either by taking issue with it or by simply restating the reproach as though no account was given. When the offender offers a remedy that is rejected, the friendship may be over.

The repair ritual provides friends with the means to restore a friendship following conflicts that range from embarrassing situations to relational transgressions. There may be other ways to restore or preserve a friendship without confronting the other and attempting to repair the friendship by resolving the conflict. People may choose to avoid the relationship issues raised in a conflict and act as though nothing happened. Or they may get back together after enough time passes. Based on the idea that it is better to be proactive than reactive, probably it is best to understand what it means to be a friend and abide by the rules of friendship.

FRIENDSHIP FORMATION AND DEVELOPMENT

In the classic film *Casablanca*, the saloon owner delivers a famous line: “Louis, I think this is the beginning of a beautiful friendship.” This entry addresses questions surrounding the beginnings of friendships. How do people “make” friends? What is the process by which an acquaintanceship is transformed into a friendship? Research reveals that friendship formation is a complex process in which a number of factors must converge. First, the *environment* must bring two people into contact with one another. Second, the *situation* must be “right” for a friendship to develop. For example, both people must be at a point in life where they have the time and resources to devote to a new friendship. The qualities that people possess also play a role in friendship formation; *individual* factors such as attractiveness and social skills matter. Finally, friendship is ultimately a *dyadic* process. In other words, it takes two to form a friendship. As will be seen, friendships are more likely to form when the two people share important similarities, when liking is mutual, and when self-disclosures are reciprocated.

The Environment

For a friendship to develop, two people must be brought into contact with one another. The role of

physical proximity in friendship formation is well documented. For example, in a classic study, married students living in a student housing complex were asked to name the three people in the complex with whom they socialized most. Two thirds of the people named lived in the same building, and two thirds of these people lived on the same floor. Other studies have shown that people are likely to form friendships with those who live nearby (i.e., residential proximity). Proximity effects also have been shown in the workplace, in college dormitories, and in classrooms.

What is it about neighborhood, workplace, and school settings that promotes friendship formation? The short answer is that these settings provide opportunities for contact. The greater the amount of contact between two people, the greater the likelihood that they will become friends. However, physical proximity is becoming less important than it was in the past. Many people are now relying on the Internet as a venue for meeting potential friends. Thus, it is possible that in the future, environmental factors will be less crucial for friendship formation, although the people with whom we rub shoulders on a day-to-day basis will probably continue to be candidates for friendship formation.

The Situation

A number of “chance” factors influence whether or not friendships develop. One such factor is whether the two individuals will have opportunities for ongoing interactions and whether they will be able to interact on frequent basis. Importantly, both people also must be “available” for this kind of relationship.

Opportunities for Interaction

When two people meet each other, they usually know whether this is likely to be a one-time occurrence (e.g., chatting with a fellow passenger on an airplane) or whether their interactions will be ongoing (e.g., chatting with a new coworker). We are more likely to pursue a friendship with a person when we believe that there will be future opportunities to interact with him or her. This was demonstrated in a classic study in which research

participants watched a videotape of three people having a discussion. Some participants were led to believe that they would not be meeting anyone on the videotape; others were told that they would have a one-time meeting with one of the people on the videotape; still others were told that they would be meeting with one of the people during the next 5-week. Those who expected to meet during a five-week period rated the person in the videotape the most positively, followed by those who expected a one-time meeting. Those who did not expect to meet at all provided the least positive ratings. Other studies have shown that when we expect to interact with someone over an extended period, we tend to emphasize the positives and downplay the negatives so that our future interactions with the person will be smooth and enjoyable.

Frequency of Interactions

As just discussed, if we anticipate future interactions with a person, we evaluate him or her more positively than if we do not. Does the frequency of those interactions matter? The answer is yes. Considerable research shows that the more often we see someone—or even a photograph of a person—the more we like him or her. This phenomenon is referred to as the *mere exposure effect*. There is one exception: If we initially dislike someone, repeated contact can cause us to like the person even less. In general, however, the more contact we have with a person, the more we will like him or her, and the greater the probability that a friendship will form.

Availability

We do not form a friendship with every person with whom we have ongoing interactions. Another factor must be considered, namely whether we have room in our lives for a new friendship. Friendships require a number of resources—time, energy, and even money. Other commitments in life, such as time-consuming studies, work demands, and existing relationships (romantic partner, family, friendships) can prevent us from pursuing a promising new friendship. A friendship can form only if each person is available for this kind of relationship.

Thus, circumstantial factors affect the development of friendships. Friendships are more likely to

form if two people expect that they will have ongoing interactions, that they will be able to see each other on a frequent basis, and when each person has the time and energy to devote to forming a new relationship.

The Individual

Even if the situation is “right” for the development of a friendship, there is no guarantee that a friendship will form. Another important class of variables comes into play, namely whether the other person has qualities that we want in a friend—and vice versa. A number of characteristics make a person a desirable friendship candidate, including physical attractiveness, social skills, and responsiveness.

Physical Attractiveness

It is well known that looks are important in determining attraction to potential romantic partners. However, physical attractiveness also matters in the friendship selection process. Research conducted with adults and children shows that physical attractiveness is correlated with popularity—the better looking someone is, the greater the likelihood that he or she will be sought out as a friend.

Why are good-looking people at an advantage when it comes to making friends? One reason is the tendency to assume that “what is beautiful is good.” In other words, when people are attractive on the outside, we assume that they also are attractive on the inside and attribute positive qualities to them. Research also has shown that we assume that people who are good looking are similar to us in personality and attitudes. (As is discussed later, it is well-established that we are attracted to similar others.) Finally, evidence also indicates that people who are physically attractive may have better social skills than do those who are less attractive. From childhood on, good-looking people experience positive reactions from others, which results in increased self-confidence and social competence. Thus, interactions with physically attractive people may actually be more enjoyable than are interactions with those who are less attractive. There are a number of reasons, then, why good-looking people are pursued as friends.

Social Skills

It has been said that making friends is a skilled performance, much like learning a new sport or learning to drive a car. Research conducted with adults and children confirms that people who have good social skills are liked more than are those who are less socially skilled. Social skills include being competent at initiating conversations, asking appropriate questions, and showing interest in what the other person is saying. Social skills also include nonverbal behaviors such as appropriate patterning of eye contact and gaze and following norms for interpersonal spacing (e.g., respecting the other's personal space). Social skills are crucial at the beginning stage of friendships; those who are socially skilled are better at getting friendships "off the ground." Once a friendship is established, however, it becomes less important to be socially skilled and more important to be competent in providing warmth and support.

Responsiveness

Another individual-level characteristic that is closely related to social skill competence is responsiveness. A responsive individual pays attention to questions he or she is asked and makes appropriate, relevant responses. These behaviors convey interest, liking, and concern. As a result, the interaction partner feels more comfortable opening up, which, as we shall see, is an important element of the friendship formation process (see section on Self-Disclosure). Indeed, several experiments have shown that when people are interacting with a responsive (versus a nonresponsive) interaction partner, they feel liked by him or her, they report greater liking for him or her, and they see the person as someone who potentially could become a friend.

Thus, several individual characteristics are associated with friendship formation. Those who are physically attractive, who have good social skills, and who are responsive are likely to be sought out as friends.

The Dyad

A friendship is a relationship between two people. Thus, analyses of friendship formation must consider the characteristics of each individual, as well

as the interplay or the "chemistry" between them. As discussed next, friendships are most likely to form when liking is reciprocal, when self-disclosure is mutual, and when the two people share similarities.

Reciprocal Liking

"How I like to be liked, and what I do to be liked!" These words, penned by the 19th-century English writer Charles Lamb, are as applicable today as they were 200 years ago. In a classic demonstration of this phenomenon, groups of same-sex strangers engaged in weekly discussions during a 6-week period. Before the first meeting, each participant was told that based on personality information gathered earlier, the researchers could predict which group members would like him or her. (The names of these group members were actually randomly selected.) As expected, participants expressed the greatest liking for those group members who they believed liked them.

Interestingly, the perception that another person likes us may cause us to behave in ways that confirm that expectation. In another landmark study, researchers led participants to believe that their interaction partner either liked or disliked them. Those who believed their partner liked them engaged in more intimate self-disclosure, were more pleasant, and demonstrated fewer distancing behaviors than did those who believed they were disliked. Importantly, these behaviors lead the interaction partner to like them. Thus, when another person likes us, we tend to like them in return. Even the belief that another person likes us creates liking because it puts in motion a self-fulfilling prophecy whereby we behave in ways that produce the liking that we initially expected.

Self-Disclosure

We are generally attracted to a person who self-discloses to us because revealing personal information sends a message that he or she likes us and desires a closer relationship with us. Indeed, many studies have demonstrated that we like people who engage in intimate self-disclosure more than we like those who engage in non-intimate disclosures. The one exception to this pattern is when another person reveals "too much too soon"—highly intimate

self-disclosures from a stranger can elicit dislike, rather than liking.

We also like those to whom we have self-disclosed. The effect of engaging in self-disclosure (rather than being on the receiving end) was examined in a study in which pairs of strangers participated in a 10-minute “get acquainted” discussion. The more a participant self-disclosed, the more he or she liked the other and saw the other person as a potential friend. Thus, in general, the greater another person’s self-disclosure, the more we like him or her. We also like those to whom we have self-disclosed.

At the early stages of relationships, it is important for disclosures to be reciprocal. If Person A reveals something intimate about himself or herself, Person B needs to reciprocate with an equally intimate disclosure. Indeed, considerable evidence indicates that reciprocity of disclosure is associated with greater liking for an interaction partner. Reciprocity is considered important in establishing trust in a relationship. When we first meet another person, we do not know whether he or she can be trusted to keep our self-disclosures in confidence, whether he or she might use the information we have disclosed to hurt us, or whether he or she might ultimately reject us. We are more willing to risk being vulnerable if the other person is also taking the same risk. Thus, self-disclosure generally takes the form of “turn taking” in which we reveal personal information and then assess whether the other person reciprocates and whether he or she can be trusted with the information that we have shared. If the other person seems trustworthy, we will gradually increase the intimacy of our self-disclosures, while monitoring whether the other person is also increasing the intimacy of his or her disclosures. Once trust is established, it is not necessary for each self-disclosure to be reciprocated in each specific interaction; rather, there is an assumption of reciprocity over the long term.

Similarity

One of the most widely researched predictors of friendship formation is similarity. A broad base of evidence indicates that people are likely to become friends with those who are similar to them in demographic characteristics (e.g., age, physical health, education, religion, family background),

residential proximity, social status, physical attractiveness, and so on. Although adult friendships are the focus of this literature, most of these effects have been obtained in studies with children and adolescents as well.

The classic domain in which similarity effects have been investigated is attitude similarity. In early investigations of the role of similarity in attraction, participants were asked to complete a questionnaire assessing their attitudes on a variety of issues (e.g., politics, religion, tuition increases). They were then shown the same questionnaire supposedly filled out by a person who would be their partner during an experiment. In actuality, the researchers completed the questionnaire so that it appeared either similar to that of the research participant or dissimilar. Participants then were asked to give their impression of this person, before meeting him or her. Those who believed that the partner held attitudes similar to their own reported greater attraction and liking than did those who believed that they and their partner held dissimilar attitudes. Subsequent research demonstrated that these findings also apply to real-world friendships, namely that people tend to form and maintain friendships with those who are similar to them in attitudes. People also tend to develop friendships with those who share their values.

Similarity effects also are pronounced for activity preferences. We are more likely to form friendships with people who enjoy the same hobbies, sports, and leisure preferences that we enjoy. Interestingly, there is little evidence that people become friends because of personality similarity, although similarity effects have been found for more relationally oriented characteristics such as social and communication skills.

There is one domain in which similarity effects are found for children’s and adolescents’ friendships, but not for adults’ friendships, namely similarity in prosocial and antisocial behaviors. These effects are strongest for antisocial behavior. For example, research has shown that aggressive children seek out other aggressive children as early as preschool and that this tendency becomes more pronounced with age. Research also shows that adolescents tend to seek out as friends those who are similar to them in drug and alcohol use and school delinquency (e.g., cutting classes, quitting school).

Overall, substantial evidence indicates that we are likely to become friends with those who are similar to us. The only area in which similarity effects seem to be weak or nonexistent is personality similarity. Thus, it seems to matter less that our friends share our characteristics, than that they share our attitudes, values, social competencies, and leisure preferences.

Why are we more likely to form friendships with similar, rather than dissimilar, others? The most common explanation is that our views are validated by interacting with someone who shares them. Put another way, we feel more confident that we are “right” in our thinking if we encounter someone else who thinks just like us. Another explanation focuses on the enjoyment of interactions. The idea is that interactions are smoother and more pleasant if we agree with another person on most things. Disagreement tends to make interactions tense and strained.

In summary, a number of dyadic factors promote the formation of friendships. The two people must like each other. They must engage in a process of mutual self-disclosure in which the intimacy of information revealed gradually increases over time. And, finally, potential friends should be similar in most ways.

FRIENDSHIPS, CROSS-SEX

A cross-sex friendship (also called opposite-sex friendship or cross-gender friendship) is a friendship between a genetic female and male in which both partners label the relationship as a friendship. Cross-sex friendships do not involve family members, are nonromantic, and are almost always devoid of sexual contact. However, teens and young adults will sometimes have what they call *friends with benefits*, which are nonromantic cross-sex friendships in which the friends have sexual relations with one another.

Most cross-sex friendship research has focused on the friendships of heterosexual individuals, with little attention given to friendships between men and women or girls and boys in which one or both individuals are gay, lesbian, bisexual, or post-operative transsexuals. Some studies suggest that the dynamics are different in cross-sex friendships in which one or both partners are not heterosexual. For example, the mutual sexual attraction that often exists in heterosexual cross-sex friendships becomes much less of an issue if one of the friends is gay or lesbian.

As suggested by the definition of cross-gender friendships, cross-sex friendships are a type of friendship, similar in many respects to other kinds of friendship such as same-sex friendships and interracial friendships. Friendships between females and

males have been documented from early toddlerhood through old age. This entry tracks cross-sex friendship initiation and development across the life span; that is, from early childhood through the twilight years of one's life. In particular, generic and unique advantages of these friendships are identified and described as well as challenges that members of cross-sex friendships sometimes contend with. The entry concludes with speculation about the future of cross-sex friendship research and theory.

Cross-Sex Friendships Across the Life Span

Cross-sex friendship scholars generally agree that friendships between females and males sometimes occur between individuals as young as one year of age. Once boys and girls reach the age of about 3 or 4, they have friendships with members of the other sex, and they recognize that their friend is of a different sex than they are, something they were not able to do if they had such friendships as early toddlers. Research indicates that friendships between young girls and boys, say between the ages of 1 and 5, are not unusual until they leave early childhood and enter into middle childhood and elementary school. This developmental transition is often accompanied by a process called gender or sex segregation. *Sex segregation* means separating the biological sexes simply on the basis of whether they are female or male, and it can be voluntary or involuntary. Voluntary gender segregation begins to occur around the age of 5 or 6 and involves the intentional separation of oneself from members of the other sex. Involuntary gender segregation occurs when adults separate children at schools and daycare centers, sometimes even at home and in their neighborhoods, according to their biological sex. For example, some of the readers might remember their elementary school teacher saying "Girls on this side of the room, boys on the other side."

When children leave middle school, most of them are in the process of entering puberty and adolescence. The biological, cognitive, and social changes that accompany puberty make it the single most important developmental stage for individuals regarding their desire to be around members of the other sex. Before the onset of puberty, children between the ages of about 6 to 10 typically do

everything in their power to avoid contact with children of the opposite sex. The hormonal and social changes that go hand-in-hand with the coming of adolescence often prompt children, who are now becoming teenagers, to break the gender barrier. Whereas cross-sex friendships were quite common in early childhood (approximately 1 to 5 years old), and nearly nonexistent in middle childhood (approximately 6 to 11 years old), once adolescence starts, the walls of gender segregation begin to crumble and individuals have more and closer cross-sex friends.

Adolescence ends and adulthood begins around the age of 18 to 20, although some researchers categorize individuals in their early twenties as still being in late adolescence. Regardless, young adults continue the pattern they started in high school in regards to the number and closeness of their cross-sex friendships. Probably more so than any other stage of the life cycle, young adults in their twenties and early thirties have a significant number of cross-sex friends, often as many as five or six. Research has demonstrated that individuals who attend college have more cross-sex friends than do those who do not, because of the increased opportunity for cross-sex interaction that college affords young people. Additionally, it is not unusual for some college students, typically females more than males, to prefer the company of cross-sex friends to that of their same-sex ones.

The number and closeness of cross-sex friends usually declines if individuals get married and even more if they have children. Investigations of marriage and its impact on cross-sex friendship shows that marriage often interferes with the formation of new cross-sex friendships because of jealousy issues. But if the cross-sex friendship existed before the marital partners met one another, the chances for its continued existence after the marriage are greatly enhanced. However, marriage sometimes will facilitate the formation of what are called *couple friendships*, which are cross-sex friendships that arise from two married couples doing things together. For example, if a woman and man are close cross-sex friends, they might introduce their respective spouses to the spouse of their friend so that they may continue to see each other and at the same time circumvent jealous suspicions from their spouse or unwanted temptations that might arise from within the friendship.

Just as cross-sex friendships have been somewhat marginalized and given less research attention than same-sex friendships and romantic relationships, older U.S. residents are also a marginalized group. This double marginalization has resulted in an embarrassingly small number of studies done on the cross-sex friendships of what gerontologists call the young-old (ages 60 to 74), the old-old (ages 75 to 84), and the very old (ages 85 and older). The scant research that has been done is dated, not allowing for the possibility that baby-boomers who are now entering old age might have a different view of the viability of cross-sex friendships than does the generation that preceded them.

Advantages of and the Challenges in Cross-Sex Friendships

Cross-sex friends across the life cycle provide both generic and unique advantages, but they also face what are sometimes formidable challenges to their initiation and maintenance. A generic advantage is an advantage that can be provided by any kind of friendship. For example, similar to all other kinds of friendships, cross-sex friends throughout the life span give one another social support in the form of affect, aid, and affirmation. Whether it is a friendship between two young children or two elderly individuals, all cross-friendships offer social support by giving help (aid) in time of need, by supplying companionship and emotional support (affect), and by making one another feel good about themselves (affirmation).

Unique advantages are benefits that are unique to cross-sex friendship and do not occur in the main type of friendship with which it is often compared, that is, same-sex friendships. For example, research has shown that men and women and girls and boys enjoy their cross-sex friendships because those friendships provide them with an insider's perspective on how members of the other sex think, feel, and behave. For instance, a woman may tell her cross-sex friend what it is like to be moody because she is on her period. This insider's perspective allows the male to better understand other females in his life who may be going through the same thing. In a similar fashion, a young teen boy may explain to his adolescent cross-sex friend

why so many teenage boys are obsessed with video games. However, researchers do not know with certainty when the recognition of an insider's perspective first arises, and it arises for different individuals at different times. Scholars speculate that the cognitive realization that one is receiving an insider's perspective and what that means becomes apparent as soon as the friends know the difference between males and females, which usually occurs around the age of 3.

The second commonly reported unique advantage of cross-sex friendship is the provision of opposite-sex companionship for the participating members. From early childhood through adulthood, females and males report that one of the intangible benefits of cross-sex friendship is enjoyment of the company of a member of the other sex. The provision of other-sex companionship is clearly linked to the first unique advantage because part of the reason why friends enjoy opposite-sex companionship is the insider's perspective that is sometimes communicated during those interactions.

Unfortunately, U.S. society often makes it difficult for men and women and boys and girls to form friendships with one another. Mass media such as television and movies do not help with their portrayals of relationships that start out as friendships, but then change into romantic or sexual relationships. For example, in the TV program *The X-Files*, which ran for 9 years, the female and male FBI partners started out as enemies, then became good friends, then lovers. Females and males who want to be friends must sometimes overcome a host of challenges. One of the main challenges of heterosexual cross-sex friendships is dealing with the romantic and sexual tensions in the friendship. Consider the case where one member of the friendship wants to redefine the relationship into a romantic or sexual association, whereas the other wants the friendship to remain platonic. This kind of challenge comes from within the friendship itself, and often the one wanting to change the nature of the relationship will attempt to do so in a less than straightforward way. Some challenges originate from outside the relationship, such as jealous romantic partners, gossipers at work, and parents who prevent their child, especially their female child, from spending time with members of the other sex. Additionally, because of

gender segregation that begins early in life and often continues into the work environment and other social settings, the opportunity for cross-sex interaction and thus friendship formation is seriously curtailed.

The Future of Cross-Sex Friendship Research

Cross-sex friendships in each stage of the life cycle are complex relationships. That complexity requires broad, focused, and imaginative research designs. Although cross-sex friendship researchers have repeatedly requested that more research be conducted on these relationships, friendships between females and males are still understudied. Explorations of cross-sex friendships are usually limited because of the atheoretical approach taken and the lack of longitudinal research. An *atheoretical orientation* means researchers collect data on cross-sex friendships without an articulated theoretical framework within which to analyze that data. Theories about cross-sex friendships could be complemented with utilization of longitudinal research designs, which are designs that allow investigators to study the same cross-sex friendships over an extended period. For example, almost no research focuses on individuals and their cross-sex friendships as they transition from one stage of the life cycle to the next, such as transitioning from middle and late childhood through the first few years of puberty.

FRIENDSHIPS, SEX DIFFERENCES AND SIMILARITIES

Attempting to capture the essential differences between women's and men's same-sex friendships, Paul Wright described them respectively as "face-to-face" and "side-by-side." Although the observation that women, compared with men, describe their same-sex friendships as more intimate, emotionally expressive, and supportive has been repeatedly verified, exploration of what this means and why it occurs continues. Too much attention to gender differences can also obscure important similarities between women's and men's friendships. This entry focuses on same-sex friendships, but cross-sex friendships will also be discussed.

Friendships are nonkin, nonromantic, voluntary, and reciprocal personal relationships. Reciprocal relationships and frequent use of the word "friend" emerge by the time a child is 4 years old. Friendships are often cross-sex in preschool, become increasingly same-sex (as much as 95 percent) during middle childhood, and then less exclusively gender concordant in adolescence and adulthood. Friends are expected to be equals, to confide in one another, to do things together, to be comfortable being one's self with one another, and to be supportive, trustworthy and accepting. Not having friends has been linked to depression, lower feelings of self-worth, and less social competence throughout the life span.

Gender Differences

Children, adolescents, and adults have been asked in many ways what they do with their friends, how they perceive their friends and their friendships, what they give to and receive from their friends and how they feel about their friends and

their friendships. A sampling of results from these studies of friendship shows that in childhood girls, compared with boys, have fewer friends but more exclusive, intimate, and expressive relationships with their same-sex friends; girls rate their best friends higher for companionship, help, security, and closeness; both pre-adolescent girls and college women report greater communion with their best friend (i.e., support, nurturance, intimacy, validation, love, loyalty, and companionship); women rate their best friends higher than men rate their best friends on supportiveness, security, concern, and desire to spend free time together; in describing providing help to a same-sex friend, women report spending more time helping; women engage in more intimate self-disclosure to a same-sex friend; women report talking to their same-sex friends more about relationships, personal problems, and secrets; women express more affection, verbally and nonverbally, toward their same-sex friends; and women use more supportiveness, openness, and interaction in maintaining their same-sex friendships.

Conversely, boys are somewhat more likely than girls are to describe their same-sex best friend as someone who fulfills instrumental needs, such as competition, status, guidance, favors, and praise for accomplishments; young men are more likely than are women to describe their same-sex closest friend as someone with whom they compete, quarrel, and tease; and men talk more with same-sex friends about sports, hobbies, work, and shared activities. Although some researchers have found that women are more satisfied with their same-sex friends, others have found no sex differences in satisfaction. Even in a sample where women reported more personal self-disclosure and involvement in their interactions with same-sex friends, women and men gave similar ratings for meaningfulness, pleasantness, and satisfaction.

Although sex differences in same-sex friendships are reliably found, they tend to be small to moderate in size, meaning that being male or female accounts for a relatively modest portion of the overall variance in same-sex friendships. A further caveat is that most data on friendships are collected from self-reports, where participants are asked to describe their relationships with friends, rather than through direct observation, making it probable that what men and women think their

friendships should be like, as well as what their friendships really are like, influence participants' responses.

Gender Similarities

Despite these many differences, women and men generally share similar views of same-sex friendships, valuing intimacy, trust, emotional closeness, and self-disclosure. Also, when researchers focus on within-gender differences rather than between-gender differences, similarities emerge. Although women may give higher ratings than do men on some measures, the rankings for what women and men value in friendships tend to be similar. For example, when describing ideal and real same-sex best friends, women and men rate communal characteristics, such as support, intimacy, and loyalty, higher than instrumental ones, such as competition, status, and network access. Both women and men agree that self-disclosing interactions create more intimacy in friendships than activity-based interaction does. Both women and men recognize connection as the most important goal in same-sex friendship and trust as the most valued quality of a friend. These friendship characteristics have also been found to predict friendship quality for both women and men. Finally, data from diary techniques indicate that friends spend most of their time together talking and that women and men do not differ in this regard.

Understanding Differences

If women and men value similar friendship qualities, then why are women's same-sex friendships consistently rated as higher in intimacy and closeness? Beverley Fehr asked women and men to generate descriptions of behaviors that contribute to intimacy in friendships. Frequent responses involved self-disclosure and emotional support, and these were generated equally by women and men. On the other hand, women were more likely than men to regard these behaviors as central to friendship intimacy. Violations of these intimacy patterns were perceived by women as more damaging to friendship intimacy and by both men and women as more damaging if they occurred in a female same-sex friendship compared with a male

same-sex friendship. Thus, women have both a stronger belief in the importance of self-disclosure and emotional support to intimacy in friendships and, as many studies have shown, are more likely to engage in these behaviors. Researchers studying these patterns have generally concluded that men simply prefer not to engage in these behaviors that lead to closer and more intimate friendships.

If men and women agree on the path to friendship intimacy but women choose to travel further down this path than men, are there barriers to intimacy in men's same-sex friendships? Barbara Bank and Suzanne Hansford found that emotional restraint and wanting to maintain distance from gay men were most helpful in explaining gender differences in intimacy and support in a same-sex best friendship. Having no role model (a same-sex parent with close friends) reduced the effect of gender on supportiveness, and masculine self-identity reduced the effect of gender on intimacy. The authors concluded that men's tendency to be emotionally cautious and reserved with their male friends may account to some extent for their failure to establish more intimate and supportive same-sex friendships. Although these barriers to male friendship contributed to explaining sex differences in friendship intimacy and supportiveness, these barriers did not eliminate the differences, suggesting that although characteristics of the male role do help us understand these gender differences, they do not fully account for them.

Although men have been described as not preferring behaviors that promote closeness and intimacy, it may be that they choose these behaviors without necessarily preferring them. Evidence indicates that men would like more openness in their same-sex interactions and that given the proper context, they are willing to express affection toward same-sex friends. Men may also suffer more from these choices; failure to meet communal needs in friendships was found to predict loneliness for men but not for women.

Recent research has included a focus on the instrumental aspects of same-sex relationships in addition to the more frequently studied communal aspects. Results for sex differences are mixed. Lynne Zarbatany and her colleagues found that boys and men prefer friends who provide competition, encouragement, and status and who are

influenced by their actions and opinions, but Bank and Hansford, measuring status orientation toward friendship, found that women were more likely than men to want friends who respect and depend on them and who are influenced by them. These noncommunal characteristics of friendship also appear to contribute positively to friendship quality. Researchers might also pay more attention to the ways in which friendship interactions provide fun, relaxation, and relief from boredom. Integrating both instrumental and communal aspects of relationships may be critical for establishing effective friendships. That Joyce Benenson and Athena Cristakos found that adolescent females have same-sex best friendships of shorter duration and more former best friends, suggesting in their words "greater fragility," indicates that there is more to know about friendships than just how close and intimate they are. Rather than focusing on men's problems with friendships, the field might better address the multifaceted benefits of friendships, the strategies that women and men use to accrue these benefits, and the barriers they each experience in meeting their friendship goals.

Cross-Sex Friendships

Less research has addressed the experience of cross-sex friendships. Cross-sex friendships are common in preschool children, become rare in middle childhood and reemerge in adolescence and young adulthood, becoming less frequent again as adults enter marriage and parenthood. Romantic partners and spouses are often viewed as close, or even best, friends. For research purposes, however, cross-sex (and same-sex) friendships are defined as nonromantic relationships. There is less research on cross-sex friendships, and results may be affected by the age of the sample and the nature of the measures. In general, results suggest that females receive fewer benefits from cross-sex friends than males. Men rate their cross-sex friendships higher on enjoyment, nurturance, and overall quality than women rate their cross-sex friendships. Men have also been found to rate their cross-sex (female) friends as more accepting, intimate, and emotionally supportive than are their same-sex friends.

Guys, Lesbians, and Friendships

Same-sex and cross-sex friendships are generally assumed to occur between individuals with a heterosexual orientation. But sometimes this is not the case. In studies of teenagers and young adults with homosexual orientations, Lisa Diamond and Eric Dube found that lesbians had particularly strong connections to other females, as friends, best friends, and attachment figures; whereas gay men were the least likely, compared with lesbians and heterosexual youth, to have same-gender best friends and more likely than others to form cross-gender friendships. Conversely, Peter Nardi and Drury Sherrod, with an older sample, found no differences between lesbians and gay men in their ratings of same-sex friends on satisfaction, social support, self-disclosure, or activities. Nardi and Sherrod did find, however, that many lesbians and gay men reported having had sexual relationships with their friends.

Structural Factors in Friendships

Friendships, being voluntary and nonobligatory, are often studied as if they were context-free. One context that has received some attention is culture. Although most studies of friendship, including those previously mentioned, are based largely on North American samples, researchers have studied the influence of collectivistic and individualistic cultures on perceptions of same-sex friends in childhood and adulthood. Although there were differences based on culture, these were not affected by gender; in other words, culture influenced both sexes equally. Virgil Sheets and Robyn Lugar, comparing friendship in Russia and in the United States, found stable gender differences across countries, but Russian men were particularly unlikely to have cross-sex friends. Culturally defined gender roles may have a particularly strong effect on cross-sex friends.

Other contextual factors may also affect gender and friendships. In the workplace, for example, gender similarities were found on measures of quality of same-sex friendships. Social settings—such as school, work, neighborhoods, churches, interest groups, and sport teams—also provide

opportunities for friendships. They may play differential roles in the formation and maintenance of friendship. Might one be more likely to share activities with a friend made at work or through team sports but self-disclose and provide support with a friend from the neighborhood or an interest group? The structural factors that influence friendships and perhaps help account for the gender differences described here are just beginning to be defined and explored.

FRIENDSHIPS IN ADOLESCENCE

This entry addresses conceptual views and research findings pertaining to friendships during the second decade of life. In many respects, friendship sits at the frontier of adolescent social development. Friendships provide the formative context for learning the complex close relationship skills needed to establish close emotional bonds with people outside the family. These bonds help teens move beyond childish dependencies on parents toward autonomous independent lives as young adults, thus serving as a bridge between childhood attachments to parents and adult attachments to spouses and children. Friends also shape adolescent character and personality development. As teens begin to make their own choices, they gravitate toward the social niches they find most appealing and comfortable. Their chosen friends often share similar preferences and identities that reinforce and amplify their own emerging characters. Friends also “co-socialize” each other when they test limits together and encourage conformity to peer-group norms. Thus, it is not surprising that friendships exert heavy sway over teenagers’ emotional well-being. The challenge of making and keeping friends is the source of considerable stress and anxiety, and youth who are excluded or without friends suffer painful loneliness and depression. At the same time, friendship is the source of immense excitement and camaraderie. Adolescent friends serve as vital allies and supporters in times of need and may afford experiences of intimacy and affection remembered for a lifetime.

Transition From Childhood to Adolescent Friendship

Considerable research documents changes in the features of friendship from childhood through adolescence. Preschool playmate preferences are transformed during the grade-school years into true dyadic friendships in which children reciprocally identify themselves as friends, spend time doing things together inside and outside school, and are able to cooperatively play together. These friendships unfold within the broader context of

classroom peer-group status; most everyone likes popular children, most everyone dislikes rejected children, and neglected children are neither liked nor disliked by classmates. Rejected children are most likely to be friendless, often because of some combination of their own aggressiveness, poor social skills, or other “misfit” characteristics. Overall, about 85 percent of all children have at least one reciprocated friendship, with most children having two to four good friends.

Whereas childhood friendships are based on propinquity (proximity) and similarity of objective characteristics, children are especially drawn to peers who share their interests in particular activities, be it competitive sports, computer games, social conversation, or academic subjects. Dyads tend to be highly segregated by age and gender, with opposite-sex friendships viewed as atypical. Theorists have argued that the self-imposed isolation of boys’ and girls’ friendships creates different socialization cultures, with girls’ friendships fostering a more connection-oriented focus on talk and close relationships, whereas boys’ friendships foster a more agency-oriented focus on activities and competition. As children approach the teenage years, these gender barriers collapse as sexual and romantic interests erupt.

Early Adolescence

Abilities for thinking abstractly and idealistically emerge during early adolescence. This cognitive transition coincides with pubertal maturation, which happens about 2 years earlier among girls (9–12 years) than among boys (11–14 years). Paralleling these maturational changes, friendship becomes more talk focused and emotionally intimate in quality. Gossip about peers is a mainstay of conversation. A good deal of gossip is malicious in nature, with teenage friends sharing the latest news about so-and-so and critiquing the appearance, behaviors, and motives of fellow peers. At times, this type of gossip is used as a form of social aggression. Youth insult, criticize, and spread disparaging rumors about enemies and rivalries in attempts to get back at, or gain social advantage over, them. Researchers originally thought that such relational regression was the province of girls, but more recent research shows that boys also engage in aggressive gossip. Boys, however, engage

in substantially more physical aggression than do girls, and thus girls engage in more social aggression relative to physical aggression.

But not all gossip is motivated by cruel intentions. One psychological benefit of gossip is enabling collaborative construction of opinions and values. Through hours of conversation, friends explore and arrive at their conceptions of others and themselves. Gossip also builds intimacy and closeness between friends. Self-disclosure requires that friends be trusted to keep secrets and remain loyal when other peers entice them to disparage teens behind their backs. Friends show their trust by disclosing risky opinions, which enhances felt intimacy when opinions are mutually shared. Thus, intimate self-disclosure, trust, and loyalty all intertwine to become the key features of early adolescent friendship.

This talk-focused feature of friendship is more characteristic of female than of male friendship and begins earlier for girls than boys. The growth of gossip and intimate talk roughly parallels the timing of pubertal development. For girls, there is rapid increase in the frequency and depth of intimate disclosure among friends between 9 to 14 years of age, whereas for boys what growth occurs takes place between 12 to 17 years of age. Indeed, only when boys establish romantic attachments in later adolescence do they manifest the same levels of conversational intimacy that girls generally achieve in early adolescent friendship.

The broader world of peer relations also grows more complex in early adolescence as teens move into large middle schools with rotating class periods. Crowd identifications (jocks, nerds, skaters, or druggies) heavily influence friend selection, with teens gravitating toward peers who are “like me” and away from members of crowds “not like me.” Interactions with friends take place within smaller cliques of friends rather than in large-crowd activities. Friendship cliques typically have 2 to 12 members, with an average of 5 friends, who often do things together such as sleeping-over, hanging out at malls, or going to movies as a group. Some cliques, such as the popular jocks and cheerleaders, have generally higher status than other cliques do, but most cliques differ more in qualitative characteristics than in status.

Life within friendship cliques has its highs and lows. Doing things with a group of friends is

exciting and fun and sometimes pushes the limits of risky activities. Inclusion by the group creates a genuine sense of belonging; being excluded or relegated to marginal status is painful. Jealousies among clique members are not uncommon. These inter- and intra-group dynamics can involve relational aggression where some teens engage in disparaging gossip intended to sabotage others’ standings in cliques for personal gain or to retaliate for perceived slights. Being without a friendship clique, however, is associated with loneliness, boredom, and depression. Having just one close friend tends to mitigate feelings of loneliness and alienation. Although exclusive “best friends” are more the exception than the rule, research has found that such alliances can buffer even chronically victimized teens from adverse mental health outcomes.

Middle Adolescence

During middle adolescence, close friendships become even more talk-focused and intimate. Honest and intimate self-disclosure becomes a prominent dyadic process. Gossip, humor, social comparison, and mind reading are frequent in friends’ conversations, and these social processes often work in the service of revealing oneself to friends. Besides building solidarity between friends, self-disclosure also provides a forum for exploring self-worth and personal identity. Adolescents’ growing cognitive abilities foster introspection and evaluating self and others in terms of abstract psychological traits and dynamics. Middle adolescents are also better able to consider things idealistically and analyze how things are relative to how they could be. Conversations with friends contribute to the growth of socio-moral reasoning and the elaboration of self-concept.

Friends further come to depend on one another for emotional support. Providing support effectively is a challenging, but important role to master because it plays a key role in later romance and parenthood. Styles of support giving and support seeking in adolescent friendships are predicted by styles originating in earlier parent-child attachment relationships. Teens with histories of relationships in which they felt secure are more likely to seek emotional support from, and sensitively provide support to, their friends. In contrast, teens

who developed avoidant patterns with parents feel uncomfortable seeking support from, or providing support to, friends and therefore are likely to avoid supportive exchanges with friends. Teens who manifest heightened dependence and preoccupation with problems can overwhelm friends with excessive self-disclosure and frustrate them because the friend is unable to help relieve the teen's preoccupation with distress. As givers of support, teens showing this latter pattern tend to become overly involved in their friends' problems, alternating between becoming mired in the friend's problems or intrusively giving advice.

Two of the most common topics friends share involve emergent problems with parents and romance. Research shows that as an outgrowth of teens' desires for increased autonomy from parents, family relations can become conflicted and distant during middle adolescence. Teens often turn to friends as confidants with whom they discuss and compare family pressures. This is an important shift because, before adolescence, parents were the chief source of emotional support. Teens also typically turn first to friends to discuss romantic interests and heartaches. This is only natural because initial forays in dating and romance commonly happen in the context of mixed-gender friendship cliques. Not all disclosure and support attempts between friends, however, work out for the best. Recent research reveals an unhealthy form of "co-rumination" among friends where pairs incessantly talk their problems to death. Although such talk tends to make friends feel especially close to each other, it also seems to contribute to more, rather than fewer, depressive symptoms. This is more common among girls' than among boys' friendships.

The influence of friends seems to reach its zenith during middle adolescence. Parents and researchers have long been interested in the influence of teenage friends on tastes, attitudes, and behaviors. In the mid-20th century, adolescents' peers were seen as corrupting influences that pressured teens to conform to values and behaviors that were at odds with those of parents and the broader society. Initial research seemed to confirm this view. When surveys forced teens to choose whether to conform to parent versus friend values and tastes, teens more often sided with friends. Developmentally, conforming to peer norms rose from childhood

and peaked during middle adolescence. But subsequent research revealed a more complex picture: teens are influenced by both parents and peers, their relative influences varying by domain. In core moral, religious, and political attitudes and values, parents usually hold more sway than friends do. But in matters of fashion, tastes, and activity choices, friends usually exert more influence than parents do.

Friend influence on activity choice—especially smoking, drinking, drug use, sexual activity, and delinquency—has been of great interest to researchers. Friends are usually quite similar in their involvement in these activities. These correlations have led some to conclude that deviant friends are responsible for exerting corrupting influence on teenagers. But these correlations can also reflect the way friends are selected. Research shows that teenagers are attracted to others who share similar interests and activity preferences, as in the adage "birds of a feather flock together." In careful research studies trying to tease apart whether similarity between friends is the result of selection factors or influence factors, teenagers' levels of involvement in substance use, sexuality, and delinquency are tracked across time along with the involvement of peers who are potential friends. The findings reveal that similarity of friends is mostly because teenagers gravitate toward making friends with peers who share their interest (or disinterest) in substance use, sexual activity, and delinquency.

At the same time, evidence indicates that friends become more similar to each other across time, indicating that some influence is also taking place. This is especially true for smoking and drinking. This is because friends often take part in these activities together and thus support and implicitly encourage (or discourage) involvement. One interesting study discovered that some friends engage in "deviance training" together. Young teenage friends who intentionally misbehaved during an observational session (e.g., cursed and made obscene gestures to the camera) were more likely to commit serious crimes several years later compared with pairs of friends who behaved themselves during the session. Thus, the friends rewarded and encouraged each other for being defiant and disruptive, which led to increasing deviance in the future.

Late Adolescence

As youth look forward to leaving high school and beginning adulthood, the greater permeability of boundaries between crowds affords opportunities to explore new spheres of possible friends. The search for identity becomes more personal as older teens strive to find career, religious, political, and romantic self-definitions that uniquely fit their own identities rather than the caricatures they had adopted during early adolescence by identifying with particular crowds. Not surprisingly, the conversations between friends become both more forward- and inward-looking. Friends explore with one another their emerging philosophies of life along with their fears and hopes for the future. Moreover, friendship continues to play central roles in helping older teens achieve mature autonomy from family, explore and settle on identities, and establish truly intimate romantic attachments.

Friendships play a particularly important role in romantic development. During late adolescence, friendship cliques become more heterosexual in composition, with most high school seniors averaging two opposite-sex friendships and four same-sex friendships. This is compared with sixth grade, where on average children report no or one opposite-sex friendship and five or more same-sex friendships. At one level, mixed-sex friendship cliques provide older teens access to potential romantic partners. By going places and doing things together as a mixed-sex group, teens form friendships that can progress into romantic relationships. Clique members also introduce each other to outside friends, which further broadens the field of potential romantic partners.

At another level, mixed-sex friendship groups provide an education in how to understand and relate to members of the opposite sex. Gender socialization and early segregation of peer groups led males and females to adopt different interpersonal styles and values. The male style is organized around the pursuit of common activities and individual status. Their conversational style is task focused and blunt and places value on "being right" and showing how individuals differ from one another. By contrast, the female style is organized around sharing feelings and building relationship connections. Their conversational style is supportive and nuanced, and it places value on

affirming the partner and down-playing differences. A major developmental task of adolescence for males and females is to learn how to relate effectively to one another given their different styles. Mixed-sex friendships are a forum in which these differences are often discussed and explored. Mixed-sex clique discussions often focus on differences between men and women and how they expect to be treated in romantic relationships.

At still another level, late adolescent friendships shape "mental models" that they carry into subsequent romantic relationships. Recent research shows that the attachment security that older teens experience in their serious romantic relationships is predicted more by experiences in same-sex friendship than by experiences in parent-child attachments. Again, this highlights the role that friendship plays as a bridge between childhood dependencies on family and adult relationships. This is not surprising because of the overlapping nature of friendship and mature romance. At the core of romantic relationships are the key features of friendships: companionship, disclosure, intimacy, support, trust, and loyalty. Thus, whereas early relationships with parents create a starting point for a basic sense of security or insecurity in close relationships, experiences in adolescent friendships broaden the range of relational features and concomitant interpersonal skills that will be called upon in adult romance and marriage.

FRIENDSHIPS IN CHILDHOOD

This entry describes friendships in childhood and examines their developmental significance. Most children succeed in forming these relationships, although about 10 percent fail to do so. Enormous differences exist in the number of these relationships that children have, the traits that characterize friends, and the texture of these relationships. Friendships also change in important ways from their earliest manifestations on through childhood and into adolescence even though certain features remain constant.

Social reciprocity and mutuality are central to the meaning of friendships for almost everyone. Sometimes these reciprocities consist of equivalence in resource exchanges; mostly, however, “giving-and-taking” in a broader sense undergirds the attraction that exists between friends both in childhood and adulthood. The most significant age changes observed in childhood occur in the individual's awareness and understanding of these reciprocities and their implications. Cognitive and affective representations of friendship change considerably, but the underlying meaning structure, based in reciprocity, remains constant.

Aspects of Friendship in Childhood

Incidence

Infants and toddlers sometimes show preferences for one another, seeking out other youngsters who have been more-or-less regularly responsive to them. These preferences are revealed in the time that children spend with particular playmates and are not especially nuanced linguistically or affectively. Young children are known to be less fearful of strange situations in the company of a familiar peer rather than an unfamiliar one, but familiarity is not equivalent to friendship.

The word *friend* usually appears in the third or fourth year, and sometimes preschool-aged children miss their friends when they are absent or talked about. Usually, friendship is defined by the young child in terms of concrete reciprocities (“We play”) and, during the preschool years, approximately 75 percent have preferred playmates. Play, indeed, is the main content of the interaction between friends at this age, and the proportion of the child's time spent with specific partners is a good index to use in identifying these relationships. The number of children possessing these relationships rises during middle childhood when about 85 percent have a best friend and several good friends.

Friendship networks consisting of children and their friends are relatively small during early childhood (approximately 1.7 and .9 for boys and girls, respectively) becoming somewhat larger in middle childhood (3.0 to 5.0, depending on whether unreprocated choices are included). Amount of time spent with friends increases until adolescence, when

about 30 percent of time awake is spent with these associates.

Gender

Children's friendships are gender concordant. About 30 percent of preschool children's friends are other-sex, but this percentage declines through middle childhood reaching 5 percent and rising again in adolescence when about 25 percent of teenagers' friendship networks become mixed-sex. Other-sex friends are likely to be "secondary" rather than "best friends" throughout childhood. Girls have a higher proportion of other-sex friends than boys do, and the other-sex friends of girls are likely to be older than themselves whereas the opposite is the case for boys.

Boys and girls do not differ in the proportion of children who have friends. Every observer knows, however, that the activities of boys with their friends are different from the activities of girls with theirs. During middle childhood, intimacy is a much greater concern in girls' talk about their friends than in boys' talk. Self-ratings of their friendships by girls are more intimate than are those of boys and self-disclosure is more common. At the same time, girls employ relational aggression (including threats to terminate these relationships) more frequently than boys do. Children of both sexes understand these differences. Little is known, however, about intimacy in friendship interaction that is based in camaraderie and shared mastery.

Friendship Expectations

Friendship expectations differ from expectations about other relationships: Preschool-aged children recognize differences in social power between themselves and their parents, for example, but do not expect power differences to exist between themselves and their friends. Friends are not expected to be the help-givers that parents are, or to provoke conflict as frequently as siblings do. Companionship and intimacy are expected of one's friends, rather than compliance and conflict. Refinements in these basic differentiations among relationships occur through middle childhood into adolescence.

Friendships are understood by children to be based in symmetric reciprocity at all ages although

differences emerge in the amount, complexity, and organization of information and ideas about these relationships. Among young children, friendship expectations emphasize common interests and concrete reciprocities that occur mostly in play. Older children describe friends as sharing values and rules about loyalty and trust; friends also expect to spend time with one another and to engage in constructive conflict resolution. Adolescent friends expect shared interests, understanding, empathy, and intimacy with friends; similarity between oneself and one's friends is increasingly important.

These changes in friendship expectations during childhood are correlated with certain aspects of cognitive development, including the number of constructs children can apply to a relationship and their complexity; some writers have also linked changes in friendship expectations to changes in perspective taking that occur during childhood. Whatever the case, older children and adolescents perceive and think about these relationships in nuanced ways even though symmetrical reciprocities remain their major basis.

Behavior With Friends

In most instances, children have to be in the same place at the same time to become friends. However, propinquity does not guarantee the formation of a relationship, and initial encounters between children are largely devoted to establishing common ground or its absence. "Hitting it off" may require short or longer periods, but once this happens, communication is more connected, conflicts are managed more successfully, attention is drawn to similarities between the nascent friends, and, especially among girls, self-disclosure increases. Should common interests not be maintained after this "build up" period, relevant information must be exchanged again, much as in first encounters. Continued consensual validation and commitment are required for friendships to be maintained over the long haul.

Both preschool- and school-aged children spend more time with their friends than with other associates. Social exchanges of friends and nonfriends differ in four ways: *positive engagement* (friends talk, smile, and laugh together more than nonfriends do); *task-related activity* (friends orient to

the task at hand more extensively and spend more time on-task than nonfriends); *mutuality* (friends affirm one another more and exhibit greater mutuality and attention to reciprocity in their partners than nonfriends); and *conflict management* (while exhibiting as many conflicts with one another as nonfriends do, friends use disengagement and negotiation more frequently and use power assertion to a lesser extent). The mutuality and symmetry existing in the social exchanges between friends are reasons for suggesting that reciprocity is the sine qua non for these relationships during the first two decades of life.

Similarities Between Friends

Given the common ground that brings friends together, one would expect friends to be similar to one another in a variety of ways. Not surprisingly, then, the probability that two young children will be attracted to one another has been shown to vary according to the number of behavioral attributes they share. Also, children who are strangers initially are attracted to one another when their cognitive and play styles are similar rather than different. Actually, children are likely to dislike other children who are different from themselves. Similarities, not “opposites,” attract.

Children and their friends resemble one another closely in age, gender, ethnicity, and sociometric status (how well other children like them). Behavioral concordances can be detected among preschool-aged friends, and these grow more extensive through middle childhood. School-aged friends, compared with nonfriends, are more like one another in prosocial behavior, antisocial behavior, shyness-dependency, depression, popularity, and achievement. Friends also share biases in their perceptions of people and relationships: For example, when friends rate their classmates on aggression or shyness, their ratings are more alike than classmate ratings made by nonfriends. Considerable variability occurs, however, in the similarities existing across these behavioral domains as well as within them.

Children are similar to their friends for a variety of reasons. First, children from the same neighborhood are likely to be more similar to one another than are children from different neighborhoods; socialization histories are also likely to be more

similar. Second, children are attracted to others like themselves because of the reinforcing properties that similarity seems to encompass. Children then sort themselves out by a somewhat disorganized process that is informally called “shopping” and formally called “selection.”

Friendship similarities also derive from mutual socialization; that is, children become more alike because of their interaction over time. The extent to which selection and socialization, respectively, contribute to friendship similarity depends, however, on characteristics of the children themselves (which derive from their genetic makeup as well as their social histories), their interaction with one another, and which behavioral characteristics are being measured. For example, the genetically mediated expression of physical aggression, but not social aggression, is stronger among children who have physically aggressive friends compared with children whose friends are not physically aggressive.

Friendship Variations

Having Friends

Correlational studies show that children who have friends, in contrast to those who are without friends, enjoy better psychosocial adjustment; they are more sociable, more cooperative, more altruistic, less aggressive and impulsive, and less lonely. In most studies, “having friends” means having “good” friends or “compatible” friends even though not all friendships are harmonious. It is thus somewhat difficult to argue that merely having a friend, disregarding the nature of the relationship, facilitates good adjustment. Nevertheless, merely having friends is an indicator in longitudinal studies of good later outcomes: having positive feelings about oneself and one’s family as well as having a romantic partner in adolescence and being relatively free of depression. Most investigators interpret these findings to mean that the complex reciprocities experienced with a friend during childhood promote the kinds of social competence that make one a desirable companion later on. Disharmony between friends attenuates these benefits but, overall, childhood friendships appear to facilitate good adjustment—both at the moment and later.

Friendship Stability

Children change friends with some regularity, although childhood friendships last longer than is commonly believed. Nursery school children often maintain friendships for many months and stability increases through adolescence, at which time about 70 percent of individuals report that their friendships last a year or more. By the end of middle childhood, it is not uncommon to find children reporting friendships that have lasted between 1 and 5 years. Friendship stability, however, depends on a number of conditions. For example, relationships between aggressive, antisocial children are more unstable than are relationships between nonaggressive children. Other psychosocial difficulties are associated with friendship instability, too, probably resulting from the children's limited capacities to regulate emotion and other deficits in social skill.

Friendship stability also has implications for the child's social adaptation. For example, school-age children who have friendships that last through a school year show greater improvement in attitudes toward school and greater improvement in other school-related behaviors than do children with less stable friendships. Other implications of friendship stability vary according to the children involved. Stable friendships among children who have conduct problems increases children's own behavior problems. In contrast, friendships with shy or withdrawn children seem not to affect a child's own social withdrawal. The developmental implications of friendship stability thus differ according to the behavior being measured and aspects of the children's relationships with one another.

Who the Partner Is

Childhood friends enhance social adaptation when one's partners are socially competent but are developmental risks when partners evince poor adaptation. Examples: When friends are aggressive and antisocial, children become more aggressive over time, especially those who are disposed toward aggression and who perceive themselves as socially rejected. When children have friends and these friends are socially well-adjusted, marital disruption has fewer effects than otherwise. Finally, social adjustment improves after school transitions when friends are well-adjusted, but otherwise not.

Partner effects are not well understood. Modeling and reinforcement during interaction with friends may be responsible for some of these effects; poorly adjusted partners do not model "competence" as consistently as do better adjusted ones and may not provide social rewards for competence behaviors as regularly. In many instances, conversations also seem to be powerful mechanisms for behavior change within friendships, especially when these conversations are persuasive. Aggressive children and their friends, for example, entice one another into "deviant talk," in which rule-breaking and other aggressive activities are discussed much more frequently than nonaggressive friends discuss them. Conversations between aggressive friends also contain more conflict and aggression than the conversations of less aggressive friends. Other observations show that increased depression is sometimes an outcome when childhood friends spend inordinate amounts of time "co-ruminating," that is, talking endlessly and intensely about issues rather than letting them drop after a reasonable period. Developmental contexts thus differ for children according to who their partners are, and these differences are related to behavior change.

Friendship Quality

Friendships in childhood vary in their structural and affective qualities, and these variations are significant for adaptation. Some friendships are warm, intimate, and supportive; others are rife with conflict, relational aggression, and other disharmonies. The outcomes of friendship experience are now known to vary according to these differences, not merely according to whether a child has friends. Supportive, intimate friendship relations—at least in middle childhood—are associated with sociability, good social reputations, popularity, and avoidance of aggression. "Prosocial friendships" are linked to school achievement as well as to popularity, whereas "antisocial friendships" are linked to peer rejection and delinquency, and "socially withdrawn" friendships are associated with low self-esteem, peer rejection, and depression.

Linkages such as these are moderated by other conditions—sometimes according to other aspects of the friendship experience and sometimes according to characteristics of the child himself or herself.

For example, the positive outcomes of supportive friendships (mentioned earlier) occur mainly when friendships are stable rather than unstable. In addition, disharmony in friendship relations increases aggression in children over time, but mainly when friendships are not harmonious to begin with. Although the affective and behavioral qualities of children's friendships may be clearly related to behavior changes over time, the magnitude of these effects is often moderated by other conditions.

Developmental Implications

Family relationships in earliest childhood set the stage and carry forward to relationships that children have with their peers. The sensitivity of early caregiving and the security of early attachments are both antecedents of harmony, responsiveness, and competence in peer interaction during childhood and beyond. Linkages between family relationships and friendship, however, are less direct: Good family relations in the earliest years do not ordinarily predict friendship functioning in either early or middle childhood. Rather, the peer competence that is linked to early family relationships predicts having friends and friendship functioning in childhood. Friendships, in turn, predict individual differences in romantic relations in adolescence. These mediated trajectories have been observed in several studies and illustrate the complexity with which family relationships, friendships, and even romantic relationships are intertwined in human development. The development of antisocial behavior in children shows a similar progression. Coercive mother-child relations lead to aggressive behavior during childhood, both at home and outside; aggressive children, in turn, affiliate with other aggressive children, including those who may be regarded as friends; having aggressive friends, in turn, predicts increases in aggression and antisocial behavior as well as delinquency in early adolescence.

One exception to these developmental scenarios concerns sibling relationships. Although these relationships are sometimes thought to presage peer functioning, the evidence suggests otherwise. Although "only" children are more likely to conjure imaginary friends than are those who have siblings (suggesting some strong need for companionship in

early childhood), no consistent pattern has been found in either social or cognitive development that differentiates children with siblings from those who do not have them. Sibling relationships and friendships are, rather, quite different social contexts—especially as related to conflict. Conflicts with siblings are more intense and aggressive than are those between friends and less likely to be resolved with negotiation and conciliation. Children themselves recognize these differences.

Finally, friendships in childhood "buffer" children from family vulnerabilities and stress. For example, well-functioning friendships, as contrasted to poorly functioning ones, are linked to better social outcomes for children from dysfunctional families; few benefits are evinced, however, for children from good family environments. Once again, the developmental significance of childhood friendships is revealed in interaction effects rather than direct linkages.

Conclusion

Friendships in childhood are commonplace, and what children think and expect of them, as well as certain social interactions that distinguish them, have been identified. Yet these relationships are not all alike; considerable variation exists in how many friends children have, what partners are like, and what social and affective qualities characterize the relationships themselves. Although general conclusions can be drawn about children's friendships and their dynamics, developmental significance can only be inferred by considering these variations as they occur over relatively long periods.

FRIENDSHIPS IN LATE ADULTHOOD

For many persons, both friends and family are important for fulfillment of social needs and maintenance of well-being throughout the life cycle. Yet, by late adulthood, people vary in the degree to which friends are available in their social networks as a result of personal choices in friendship as well as circumstances that support or inhibit the development and maintenance of friendship. This entry describes developments in friendship in later life, factors that influence continuity and change in friendship, the contribution of friends to well-being, and special challenges to friendship in late adulthood.

By definition, friendship involves a voluntary relationship: Friends choose one another and are free to determine what they will do together and how often they see one another. Often this mutual

choice is based on commonalities of interests and preferred activities, shared humor, and attitudes about important issues. Fundamental to friendship is reciprocity, that is, a balanced exchange of attention, affection, and support. Considerable social skills are necessary for development of friendship and achievement of reciprocity and for the maintenance of friendships during life transitions. For various reasons friendships may end; when interactions are no longer positive, a friendship may be discontinued intentionally or may be allowed to fade away. Those that developed within specific contexts such as a neighborhood or work may end when involvement in that setting ends. Thus, a combination of personal choice and situational opportunities and constraints influence continuities and discontinuities in friendship in later life.

Relational Functions of Friendship and Well-Being

To understand why having friends is advantageous in later life, consider the functions that friendship fulfills. One of the main functions of friendship is the provision of pleasurable companionship; engaging in favorite activities and sharing stories and social rituals make being with friends especially stimulating and enjoyable. Older adults are happier in the company of friends than when they are alone or with family only, as are younger adults and adolescents. For older adults, spending time with friends helps them remain socially integrated when other roles and relationships have been lost. New friends as well as old friends may provide this kind of companionship.

Another function of friendship is the provision of support. When faced with challenging situations or transitions related to aging, friends listen to one another, show affection and concern, and offer useful information. Support from friends can be especially effective when they have been through the same transition themselves, by describing their own experience, giving advice, or suggesting alternative ways of understanding and dealing with the situation. Therefore, those facing retirement benefit from contact with friends who are already retired whereas widows and widowers seek the company of others who understand what it means to lose a partner. In the new situation, friends

support one another with the task of reorganizing their lives, whether this is because of widowhood, retirement, or other changes. Friends even socialize one another to old age, by serving as examples and exchanging information on important transitions.

When family members fail to provide sufficient practical help or are unavailable during challenging situations, friends may step in to provide the necessary aid. Usually this help is offered on a short-term basis. Friends in need of such help may be wary of asking for it or even accepting help when it is offered because this disturbs the balance of reciprocity that is fundamental to friendship. However, some circumstances promote the exchange of practical help, such as the proximity of friends in the neighborhood or special practical skills or expertise that friends are willing to share.

Although forms of support offered by friends vary, a more general function of friendship is reassurance of worth. This is because of the awareness that each party is chosen as a friend and that friends make the effort to maintain the friendship. Long-time friends are especially valuable for mutual confirmation of identity in later life, reminding one another that each is the same person despite various changes in appearance, health, and life circumstances. Thus, it is not surprising that older adults often describe old friends as their closest friendships.

Another more general feature of friendship involves sharing the process of attributing meaning to experiences as friends age together. Because of the similarities and commonalities on which friendship is based, as well as shared life history, values, and historical perspective, friends are useful as companions for interpreting and understanding new experiences. When talking with friends, people usually feel free to express their opinions or doubts, whether this involves understanding changes in childrearing practices, relationships between the sexes, politics, or personal events.

Social control involves regulating or influencing one another's behavior, thereby encouraging compliance with social norms. Although social control is not a function usually associated with friendship, when one regularly interacts with friends, a certain degree of social control is likely to develop. For example, friends often exchange information about their current health situation and develop shared norms about when to see a doctor, change

medication, or adopt a calmer life style in late adulthood. They also provide one another direct feedback and advice on such matters.

This review of the functions that friendship may fulfill in later life shows that friendship is a multifaceted relationship that contributes to well-being in various ways. The pleasure and stimulation of companionship with friends and reassurance of worth that they provide have a direct effect on happiness and life satisfaction. Because friends contribute to fulfillment of a variety of social needs, they are important in preventing or reducing loneliness in later adulthood. During stressful life events or transitions requiring adaptation, support from friends often has a buffering effect, reducing stress and other negative emotional consequences and contributing to positive adaptation. Furthermore, friends also contribute to social integration; involvement in regular social activities with friends is associated with better physical and mental health, as well as lower mortality than is found among those who are socially isolated in later life.

Who Is Likely to Have Friends Available?

Throughout adulthood, individuals demonstrate considerable variation in the tendency to maintain existing friendships and to develop new friendships under changing circumstances. In a study on older persons' life histories with respect to friendship, Sara Matthews identified three friendship styles. Those with an *acquisitive style* had continued to accumulate friends throughout their lives. Some had friends from various life periods (childhood, adolescence, early and middle adulthood), whereas others with this style made new friends as their circumstances changed without necessarily maintaining their oldest friendships. A second style, called *discerning*, involved development of one or two close friendships that were maintained from youth through late adulthood. These friends are irreplaceable, should they be lost. The third approach to friendship, the *independent style*, involves a preference for friendly relations rather than close friendships. Those persons who are available for friendly interactions are considered one's friends; they are replaceable when circumstances change and social contacts are disrupted.

One's style in friendship influences the degree of vulnerability to loneliness in later life. Those persons with an acquisitive or independent style are less vulnerable to loneliness because of possibilities for compensating for social losses through friendship, whereas the discerning are more vulnerable because their friends are few and irreplaceable when lost. Matthews suggests that those persons who are discerning in friendship earlier on may change their orientation to friendship in late old age, leaning more toward an independent style or even becoming more acquisitive. In general, the oldest tend to broaden their definition of friendship so that "friends" remain available despite losses of friends of similar age. Neighbors, home helpers, and those one meets regularly at local activities for older adults are more readily considered to be friends in this phase of life. As a result of this process, friendships become more heterogeneous: there are greater age differences between the oldest old and their current friends and even more cross-sex friendships in late old age.

In addition to personal dispositions that influence the availability of friends, there are other social structural influences such as gender and marital status. Gender differences in friendship found earlier in adulthood continue in later life. Men tend to develop friendships based on shared, structured activities; during their working lives, friendships often develop from work-related contacts. Upon retirement, men are likely to lose contact with work-related friends. Whether or not these are replaced depends on their participation in other associations following retirement. One study found that after age 75, men were less interested in individual friendships. This may be because of the death of male friends and a desire to avoid further loss of friends.

Women's friendships involve more confiding and exchange of emotional support in addition to the companionship that characterizes men's friendship. Thus, women tend to develop more personal, multifaceted friendships. When involvement in active parenting ends, women have more time available for contact with friends; at this point, they may intensify existing friendships or develop new ones, depending on their personal disposition in friendship. Women continue their interest in maintaining and developing new friendships in late old age. Friends serve as especially valuable

resources in adaptation to widowhood because of the companionship and emotional support they provide one another. Widows have a larger pool of potential friends because more women are widowed than are men. For both men and women, personal cross-sex friendship, outside of friendship between couples, is relatively rare in late adulthood, at least until late old age.

Marital status influences availability of friends in late adulthood in several ways. Married couples often have more friends in their social networks because of the inclusion of couple-companionate friends. Married couples represent the largest social group in society so more people of similar status are available for friendship. However, married persons tend to spend less time with friends in late adulthood compared with widowed, divorced, or never-married older adults. Those living alone need to seek companionship and reassurance of worth outside the home and thus tend to have more frequent contact with friends. Men who are no longer married are at a disadvantage because they have smaller networks and fewer friends in later life. When widowed or divorced, they tend to develop new partner relationships to meet their social needs and rely less on friends than do older widows.

Developments in Friendship in Late Adulthood

By late adulthood, various transitions have taken place that affect the availability of friends in social networks. These include the end of active parenting; becoming a caregiver for older parents, the partner, or (grand)children; retirement from the workforce; relocation; changes in health; and widowhood. These transitions affect social needs and the time and energy available for friendship, as well as proximity to friends and the commonalities which friends share. All parties involved in friendship undergo such transitions in the course of late adulthood, so they represent a challenge to the durability of friendships.

Two theories on adaptation in late adulthood are relevant to developments in friendship in this phase of life. According to the social compensation model, individuals strive for continuity in their social involvements and activities. When a particular relationship is no longer available or particular

social activities cease, people tend to develop new relationships or social activities to maintain their customary social life style. If friendships are lost, then older adults will be motivated to develop new friendships, according to this model. When social activities are lost, adults will tend to seek out other social activities that can serve as contexts for the development of new social contacts. This model predicts continuity in the availability of friendships in social networks, partly because of the development of new friendships in late adulthood.

Socioemotional Selectivity Theory focuses on changes in goals that individuals strive to achieve during the life course. Acquisition of information and emotional regulation are considered as two of the main goals in social relationships. As individuals realize that the time they have left to live is limited, they become increasingly oriented toward maximizing benefits in the present. Therefore, engaging in interactions with persons with whom positive emotional experiences are more likely and avoiding interactions with those with whom the quality of interactions is uncertain or likely to be negative become increasingly important. As a result of the change in time perspective, older adults become increasingly selective in their social relationships. They prefer to interact with close family members and their closest friends and spend less time and energy on maintaining more distant relationships, including less close friendships. This is presumably a universal process that affects most persons in late adulthood and will thus influence the mutual selection process involved in maintaining friendships. Thus, this model predicts decline in the number of friendships that are maintained in late adulthood compared with those in earlier phases of life.

Longitudinal studies on large representative samples of persons in late adulthood tend to find a decrease in the number of friends in personal networks as individuals age. This is due to loss because of death, illness, or relocation of friends, as well as the process of selection. However, studies that focus on adaptation to important life events or transitions, such as becoming widowed or relocation to retirement community, report increases in the number of friends or in the time spent with friends within the first few years following the transition. Following retirement, women also tend to increase involvement with friends. It appears

that women are more inclined to seek the support and company of friends while adjusting to a major transition in late adulthood. This effect does not seem to be apparent for men following retirement or loss of the partner. These findings suggest that during transitions that disrupt social involvements, friendships may be intensified and friendship networks may be expanded, which supports the notion of social compensation (at least for women). The two processes of selection and compensation in social relationships are not necessarily contradictory, but can be seen as complementary. Whether or not they are influential in a particular phase of life depends on the circumstances of individuals in that phase and the personal disposition or inclination to seek compensation for loss of activities and relations through friendship.

Challenges to Friendship in Later Life

The general decline in friendship with age has been mentioned, as well as a variety of factors contributing to its impermanence. An important factor is the voluntary nature of friendship; the two persons who are involved in a friendship need to be committed to the continuation of the relationship. As individuals develop with age, they may no longer share the commonalities in interests and activities that form the basis of a friendship. Changes in health status may interfere with the ability to engage in preferred activities with friends; furthermore, it may become difficult to maintain reciprocity in the friendship as a result of differences in health status. As mentioned earlier, the process of socioemotional selectivity affects friendship as individuals age; an increasing preference for interaction with one's closest relations, including friends, means that less close friendships will be dropped or allowed to fade away. The arrival of grandchildren may cause some older adults to focus more time and energy on children and grandchildren and less on friends. Thus, preferences for particular friends (or relatives) are influenced by developments in the lives of all parties involved.

Changes in circumstances with age also influence whether or not friendships are continued. Relocations of friends that reduces proximity will have a stronger effect on casual friendships than

on close friends, who are more likely to use the available communication channels such as telephone and Internet to maintain contact. Changes in marital status or occupational status also influence commonalities that older adult friends share, which in turn influence the likelihood that friendship will be continued or the intensity with which they are continued. It is often a challenge for a member of a new couple or a newly single older adult to maintain contact with older friends who shared one's former partner status but not the new one.

Another reason for discontinuing friendship arises when overt problems develop in friendship. These may be because of violations of the implicit rules that govern friendship, such as the discovery that a friend is not trustworthy, does not respect one's privacy, or has become overly critical. A conflict of loyalties may arise between one's partner and a friend or between two different friends. Those who have more friendships tend to have more problematic friendships in late adulthood. Unfortunately, little is known about the reasons for maintaining a problematic friendship, rather than ending it actively or passively.

Some friends are discontinued or lost in later adulthood, but long-term friendships that have faded into the background of social lives during middle adulthood because of preoccupations with career and family life may be revived. Retirement, widowhood, and relocation are transitions that lead to reassessment of social needs and opportunities. Naturally occurring reminiscence may increase one's longing for contact with old friends, as well as curiosity about them in later adulthood. Reunions of various sorts provide contexts for getting back in touch with former friends; the Internet also enables people to find one another many years after losing touch. Renewed contact may lead to rejuvenation of old friendships, when those involved discover that they still have much in common and that one another's company is still stimulating and a source of pleasure.

Friendship is a dynamic type of relationship during the life cycle, subject to many personal and situational influences. When asked about the importance of friendship in their lives, most older adults describe this type of relationship as (very) important. The efforts that are made to maintain or revive old

friendships, and to develop new ones, attest to the significance of friendship in late adulthood.

FRIENDSHIPS IN MIDDLE ADULTHOOD

In midlife, generally defined as the period between young adulthood and old age, friendships provide affection, companionship, understanding, and social support and therefore contribute to well-being.

Friends can also affect the status, power, wealth, attitudes, behaviors, and values of middle-aged people. In addition to these consequences for individuals, midlife friendship patterns can affect society, such as by reinforcing the class structure and upholding the institution of marriage. Friendship is thus an important type of human relationship during this stage of life. This entry synthesizes what is known about the interactive processes exchanged between friends during midlife, the internal structure of midlife friendships, and how these friendships vary across contexts and individual demographic characteristics.

In Western societies, friends are not determined by blood ties, as relatives are, or by residence, as neighbors are. This absence of a structural definition of friendship results in a lack of clear consensus about which relationships are considered friendships and about the normative expectations relevant to this type of relationship. Although scholars have generally conceptualized friendship as a voluntary relationship between equals, research shows that individuals use the term to refer to relationships that do not meet these criteria, sometimes applying it to mere acquaintances and sometimes reserving it for intimates. Despite this variation in the use of the term, however, most people define *friendship* social psychologically and, more specifically, affectively, as a close relationship with nonkin.

With age, opportunities for and constraints on friendships change and people approach friendship with different attitudes, skills, and dispositions. Although people experience the middle years in different ways, midlife is the stage of the life course with the potential for the most responsibilities. Not all middle-aged people are committed to partners, have children, are employed, or care for older adults in their families, but these circumstances are expected of middle-aged people in Western society and can affect friendship. For example, involvement in a committed romantic partnership sometimes means dropping some friendships, adding new ones, and spending more social time with couples. Children absorb a great deal of time, which can interfere with friendship, but they also provide new sources of friends for their parents—the parents of their friends. Caring for an aging parent can limit the amount of time available to spend with friends, but can also widen a social

circle, for example by adding acquaintances from the parent's neighborhood or from a caregiver's support group. Similarly, work both uses time that could be spent socializing and provides new opportunities for friendships with coworkers.

Friendships of midlife adults are also likely to differ from those of younger or older persons because of the developmental maturity often characteristic of this stage of life, such as an ability to handle a highly complex environment, the emergence of a highly differentiated self, and an achieved balance between productivity and stagnation. Midlife friendship patterns are thus different than those of younger and older people. Furthermore, concurrent sociological and developmental forces affect midlife friendships, as do prior experiences. Given that the longer people have lived, the more time they have had to follow different paths, friendship patterns are more varied across individuals during midlife than they are during earlier periods of life.

Unfortunately, given the importance of friendships during middle age, few studies define *midlife* theoretically. Most of what is known about midlife friendship is derived from general samples of adults, which sometimes include participants as young as 18 years and as old as or older than 65 years. Even those studies that focus on midlife adults often impose arbitrary age boundaries on the category rather than using theoretically derived definitions of stage of life course or level of developmental maturity to determine which adults should be included as participants. In a sense, midlife is the residual age category and sometimes represents the norm against which people of other ages are implicitly compared. The literature on children, college student, and older adult friendship is thus larger than the literature on midlife friendship.

Although scholars from many disciplines have contributed to the study of friendship, collaborations among scholars from these different disciplines are rare. For this reason, the literature on friendship in general and on midlife friendship specifically is somewhat fragmented. Psychologists and communication scholars tend to study dyadic processes using experimental methods on convenience samples of volunteers. Sociologists (and some anthropologists) study network structure, usually conducting small-scale surveys of

specialized populations. Finally, some historians, anthropologists, and sociologists study midlife friendship qualitatively in context, describing case studies in detail without comparing friendships across contexts.

Interactive Processes in Friendship Dyads

Interactive processes are the action components of friendships or what is exchanged between friends, including what they do with their friends and how they think and feel about them. Perhaps because researchers have assumed all friends feel close to each other, they have concentrated on studying friendship behaviors and cognitions rather than focusing on the feelings involved in friendship.

Recent studies of midlife friendship behavior focus mainly on communication patterns, social support, and conflict. Friends communicate better than acquaintances do because they share more mutual knowledge, display greater levels of self-disclosure, are more relaxed with each other, exchange more information, and communicate more positively in ways that build morale. In midlife, women are more likely to emphasize the importance of self-disclosure in their friendships than men are, and women tend to discuss different topics with their friends than men do. Women friends tend to discuss intimate relationships, reveal their fears and doubts, and talk in depth about personal problems. In contrast, men friends are inclined to talk about sports, business, and politics.

Research on social support by friends in midlife is concentrated on studies of women. A particularly important feature of women's closest friendships at this stage of life is the emotional support they provide. This research also shows that women rely more heavily on friends than on family members in the aftermath of difficult events (e.g., an abortion or a diagnosis with a chronic illness). One possible explanation for this finding is that midlife women's friends tend to be other midlife women who, by virtue of their age and sex, are more likely than partners and other family members to have experienced the same problems or to have thought through how they would handle them.

Scholars have also examined relational conflict during midlife, including disagreements over beliefs

and values and those regarding habits and lifestyles. Men's friendships involve more conflict than do women's, possibly because women who are currently middle-aged or older have been taught to suppress or avoid conflict. Conflict is also less common in same-sex friendships than in opposite-sex friendships, and middle-aged and older people work harder at resolving conflicts with their friends than younger people do.

Researchers have also studied cognitive, processes in midlife friendships. Research shows that, like in younger and older people's friendships, similarity of values, interests, and background is important in middle-aged people's friendships. These similarities contribute to the ease of communication and the likelihood of shared experiences. Midlife friends also evaluate each other on the basis of politeness and friendliness.

The way people describe their friends and the meaning they attribute to friendship do not vary much across ages, but the discrepancy between how people describe real friends and how they describe ideal friends differs across age groups. Differences in descriptions of real and ideal friends are smallest among middle-aged people. This might reflect middle-aged people's greater selectivity compared with younger people regarding their choice in friends and the fewer physical and social constraints on their friendships compared with older adults.

Internal Structure of Friendship Networks

Scholars have studied the *internal network structure* of friendship (i.e., the form of ties linking an individual's friends) less exhaustively than they have studied their internal processes, perhaps because the network literature tends to focus on social networks in general, without distinguishing family, neighbors, coworkers, and friends from each other and from other types of associates or because interviewing people about their networks is expensive and time-consuming.

One of the most basic structural characteristics of friendship networks is their *size*. Although some researchers have reported that the frequency of interaction with friends decreases with age or even that friendship networks are larger in midlife than in old age, the number of friends does not vary

much during the life course. A national study of U.S. residents conducted by Gallup in 2004 reported that the number of *close* friends does vary by age, at least somewhat, with middle-aged people (30–49 years, 7.0 friends; 50–64 years, 8.7) reporting fewer close friends than younger (8.9 close friends) and older adults (12.5). The variation in the average number of friendships and close friendships reported by midlife subgroups is substantial enough that reporting an overall average is somewhat misleading, however.

Even studies of friendships in a particular subgroup often have yielded different results. For example, findings on gender differences in the number of friends during midlife are mixed. Some studies show that adult men have more friends than adult women have, and other studies show the opposite depending on other characteristics of the samples. For example, some data indicate that among white-collar adults, men have more friends than women do and that among blue-collar adults, women have more friends than men do. Although the average number of friends in midlife and how this number varies across subgroups is not clear, research has shown that the size of friendship network and global measures of number of friends are associated positively with access to resources, social support, and various indicators of well-being.

Studies of midlife friendship *network density* (i.e., the percentage of all possible links among friends in a network that do in fact exist) are rare. Perhaps the two most well-known studies of adult network density are Edward Laumann's analysis of Detroit Area Study data and Claude Fischer's report on the Northern California Study. Laumann, who only examined density among his respondents' three closest friends, found that 27 percent of them had networks that were completely interlocking (100 percent dense), 42 percent had partially interlocking networks, and the rest had radial networks (0 percent dense). Fischer reported that the average density of the network of associates was 44 percent and that the more kin and the fewer nonkin in the network, the denser it was. This suggests that friendship network density, if he had reported it, would have been lower.

The density of networks is related to the processes that take place within them. For example, dense networks make it possible for information to

be transmitted quickly and therefore are easy to mobilize during crises. In contrast, confidences are less likely to be kept in high density networks and so self-disclosure is risky in them.

One of the most robust findings regarding friendship network structure is that they tend to be *homogeneous* (i.e., friends tend to occupy similar social structural positions). Studies have shown that midlife friendships are homogeneous in occupational status, ethnicity, age, marital status, income, education, gender, and religion. In general, higher status middle-aged people tend to have more homogeneous networks than do lower status people. Although sociologists generally posit a structural explanation for these findings (i.e., people, especially higher status ones, have more opportunities to meet others who are similar to themselves than do dissimilar others), preferences resulting from socialization may also contribute to the homogeneity of networks. Although findings vary across types of homogeneity, in midlife, homogeneous friendships tend to be closer than heterogeneous ones.

In most studies that include measures of friendship structure, the structural characteristics of friendship networks are used to predict outcome variables such as psychological well-being, occupational success, or educational achievement. The paucity of studies examining midlife friendship network structure is unfortunate because these are important outcomes. As the examples already provided demonstrate, some studies suggest that the internal structure of friendship networks and dyads affects the processes that are exchanged among participants. There are also fewer studies about how interactive processes sustain and modify friendship structure. For example, frequent contact with friends increases the chance that those friends know each other, so frequent positive contact increases the density of friendship networks over time.

Variations in Friendship Across Contexts

Friendships do not, of course, occur in a vacuum; they are embedded in societies, communities, and immediate social environments (e.g., neighborhoods, buildings, and organizations). Although few societal-level studies comparing midlife friendships

in different historical periods or in different countries have been conducted, since the founding of the field of sociology scholars have theorized about how the broader social context affects the friendships that take place within it. In the late 19th and early 20th centuries, for example, German scholars such as Max Weber and Ferdinand Tönnies argued that the importance of friendship had declined with industrialization and urbanization because of increasingly diverse social environments, residential mobility, and the development of impersonal bureaucracies, social forces that all are particularly salient in midlife. In a series of articles in the 1960s, Eugene Litwak rejected the notion that close relationships and bureaucratic organizations are incompatible and argued instead that they perform different, but complementary tasks. More recently, scholars have argued that in the process of industrialization and modernization, the more communal social life of the past has been replaced with a concern for the private world of home and family. Whereas in the past, social lives, including those of the middle aged, centered on relationships with coworkers and neighbors, now improvements in transportation and communications technologies have reduced the importance of local ties. Some scholars have argued that this has led to increased isolation, but others have argued that people are now free to develop a wider variety of friendships.

Only a few studies have been conducted comparing midlife friendships in across societies or periods of history in the same society, and few quantitative studies have compared midlife friendships in various communities or immediate social environments. Ethnographic studies (i.e., studies of specific settings that usually are qualitative and include observation), however, raise questions about whether findings can be generalized across contexts and suggest some connection between the characteristics of contexts and how friendship is enacted. For example, ethnographies of poor or marginal populations are more likely to discuss the closeness of relationships in a setting and to describe the social support friends provide to each other. In contrast, ethnographies of the middle class tend to describe friendships in terms of sociability rather than in terms of closeness and as focused on specific activities rather than being central to everyday survival. If the friendships in these same settings were systematically compared, quantitative researchers

would be able to document how friendship processes and structure varied across these two types of settings more precisely. Comparing these ethnographies also suggests certain characteristics of friendships are the same across contexts. For example, no matter what the setting, ethnographers tend to describe most friendships as homogeneous, probably because most immediate social environments and communities are themselves fairly homogeneous.

Individual Differences

Depending on the study, individual differences are conceptualized and examined differently. Although researchers who study dyadic processes and those who study network structure both tend to discuss individual variation in midlife friendship patterns across demographic characteristics, they use the same measures to indicate different concepts. For example, psychologists often use “sex” as a proxy measure of disposition (e.g., personality, motives, personal preferences, biologically based tendencies), and sociologists use it as a proxy measure of social structural location (i.e., external opportunities and constraints). Researchers who study midlife friendship processes tend to place more emphasis on the relationships among characteristics of friendship (e.g., such as closeness, self-disclosure, satisfaction, perceptions of equity) and less emphasis on studying individual variation within samples. In contrast, those who study midlife friendship structure tend to include many independent variables in their equations and focus on a limited number of friendship characteristics, each measured with a single item. Ethnographers do not often describe individual variation in midlife friendship patterns and when they do, interpretations of findings about how individual characteristics affect outcomes are often difficult to distinguish from contextual effects because contexts tend to be homogeneous.

However they conceptualize and interpret demographic variables, researchers study some effects more than others. Gender is by far the favorite demographic variable among midlife friendship researchers who use quantitative methods, whether they study interactive processes or internal structure. Researchers do not, however,

typically include race, ethnicity, or social class as independent or control variables in their analyses, so ethnographic case studies are the main source of information on the effects of these variables on midlife friendship patterns. Quantitative studies of friendship processes in minority populations are relatively uncommon as are those of noncollege-educated populations.

Not much is known about the effects of age on adult friendship. The information included on midlife friendship in this entry is derived from studies that are not focused on children, adolescents, young adults, or old adults. Often studies that incorporate theoretical definitions of midlife do not include people from other age groups and so explicit comparisons are not possible. When studies do include other age groups, they are typically cross-sectional and do not permit separation of age, period, and cohort effects. Much remains to be discovered about midlife friendship patterns, how they differ from friendship patterns during other stages of life, and how they vary across contexts and demographic groups.

FRIENDSHIPS IN YOUNG ADULTHOOD

Friendships are among the many personal relationships people engage in during their lifetimes. Most of what relationship scientists know about friendship stems from research on children or college students in Western cultures; however, the research that has been conducted has consistently shown that people value and enjoy their friendships, that people invest time and effort to maintain their friendships, and that people with established friendships fare better psychologically and even live longer than do those without. Benefits notwithstanding, friendships also entail costs and pose challenges. This entry discusses the importance of friendship in young adults' lives; describes the process of friendship initiation, the development of closeness, and precursors to friendship dissolution; and highlights differences between men's and women's friendships and between same-sex and cross-sex friendships during young adulthood.

Importance of Friendship in Young Adulthood

During young adulthood, a given individual is likely to be navigating myriad personal relationships, including sibling relationships, parent-child relationships, employee-employer relationships, friendships, romantic relationships, team relationships, and teacher-mentoring relationships. At this

point in life, however, friendships and romantic relationships take center stage. In one sample of unmarried college undergraduates, for example, almost half identified a romantic relationship as their “closest, deepest, most involved, and most intimate relationship” and more than a third identified a friendship. And, when young adults are asked about sources of joy and meaning in their lives, “friends” is among their most frequent responses.

A look at the quality of life during young adulthood (and in adolescence), particularly in Western cultures, might clarify the distinctive quality friendships have during young adulthood. During adolescence and young adulthood, individuals are likely to be romantically involved but not yet married or with children. Moreover, individuals generally spend a lot of time with others of their same age—in school and at play—at a time when they are exploring different relationship partners and developing their interpersonal skills and an understanding of their own enduring strengths, weaknesses, and desires and goals. Perhaps it is not surprising, then, that at this point in life, people rate companionship, emotional support, and personal disclosure as among the most important qualities of friendship. During adolescence and young adulthood, friends seem to play an integral role—through constant conversation, activity sharing, and emotional support—in each other’s understanding of self and others.

Defining Features of Friendship

Given the importance young adults attach to their friendships, one might expect to find clear definitions of friendship. However, *friendship* is difficult to pin down in a few concise words. That said, various studies consistently point to several defining features of young adults’ perceptions of friendship. First, friendships are characterized by interdependence: One person’s behavior both influences and is influenced by the other person’s behavior. Second, that interdependence is *voluntary*: Friends seek out each other’s company rather than interact by obligation (as is often the case in family relationships). Third, friends enjoy each other’s company, even if that company is not as frequent as they would like: Friends enjoy talking,

eating, and just “hanging out” with each other. Fourth, friends disclose: They reveal information about themselves to one another that they presumably would not share with just anybody. Although the degree of intimate self-disclosure varies from dyad to dyad and as a function of the sex composition of the dyad, friends tend to share their thoughts and feelings. Finally, young adults perceive friendships as involving a voluntary sense of mutual aid and loyalty. In other words, they perceive a friend as someone they can rely on and as someone who can rely on them when the going gets rough.

These defining features of friendship might also be thought of as “rules” of friendship. For example, consider a young man who is disappointed that others seem to “befriend” him only because he can help them with their math homework. One of the benefits of friendship is task support, but this young man has experienced a betrayal of the implicit notion that friendships are founded in mutual enjoyment more than task assistance. And when one woman borrows a few dollars from her friend, she might be disappointed if her friend talks incessantly of needing to be paid back so that their “score is even.” The aid and loyalty held in high regard in friendship involves not tit-for-tat exchange but, rather, the perception that the relationship has a long future—the score will even out in its own time—and that a friend will be there for them through thick and thin, regardless of the current score.

Becoming Friends

Several characteristics predict the formation of a friendship between two individuals. In young adulthood, people are more likely to become friends with frequent interaction partners, such as coworkers and individuals who live close by, than with infrequent interaction partners. As a general rule, people prefer friends (and other relationship partners) who are physically attractive and socially skilled. Related to social skill, people also tend to fall into friendships with people who they perceive as “responsive.” Responsive individuals answer questions about themselves, thus demonstrating a willingness to share a bit about themselves with others. Perhaps more importantly, responsive people also ask questions about other people,

listen to the answers, and respond supportively and sympathetically. In short, people become friends with those who display an interest in them.

People like those who are similar to themselves, and they perceive the people they like to be similar to themselves. Not surprisingly, then, individuals who are similar to each other, and who perceive themselves as similar to each other, are likely to become friends. For example, freshmen roommates in college who are placed together at random are more likely to like each other if they share similar values and attitudes. Friends are similar in many ways. They tend to be similar in age, level of education, family background, income, values, religion, political views, and the activities they enjoy. Limited research even suggests that same-sex friends may be similar in how physically attractive they are.

There are multiple, and not necessarily mutually exclusive, explanations for the similarity observed among friends (and other relationship partners). One suggestion is that humans are driven by a need for cognitive consistency, or *balance*. According to this perspective, we prefer to be around individuals who perceive other things and other people the same way we do. Another theory is that we are more likely to encounter similar others than dissimilar others, given that our interests and values guide the environments we select for ourselves. According to this perspective, it is not necessarily all that surprising when two previously unacquainted people who sign up for the same tai chi class (or any other specialized activity) realize they have much in common and quickly develop a satisfying friendship. Another prominent theory is that humans have evolved to select interaction partners who are genetically similar to themselves. In support of this theory, known as Genetic Similarity Theory, friends (and spouses) tend to be more similar to each other on characteristics that are under stronger genetic influence, such as anthropometric characteristics and highly heritable social attitudes.

Degrees of Friendship

If you ask young men and women to tell you about a friend of theirs, the first thing they will probably

do is attempt to clarify whether you want to know about a casual friend, a good friend, a close friend, or a best friend. This request for clarification demonstrates people's tendency to categorize their friendships along a continuum of closeness. Again, however, there are no concise, objective definitions of closeness but, rather, typical features. Generally, these features parallel those already mentioned earlier. In other words, each level of friendship (casual—good—close—best) is associated with increasing levels of similarity, interaction, disclosure, support, and enjoyment.

Some research suggests that people also have an intuitive perception of whether a given friend is a "true" friend or a "fair-weather" friend. A true friend seems to closely parallel people's perceptions of a "best" friend—this friend is genuinely happy for you when things go your way and would do just about anything for you when things do not go your way. Some researchers have speculated that true friendship forms under the conditions of *mutual irreplaceability*, that is, when each member perceives the other as offering him or her unique and desirable benefits that would be difficult to find in anyone else.

Types of Friendship

Young adulthood is one of the only stages in life, at least in many industrialized nations, that if you ask young men and women to tell you about a friend, they might also ask if you want to know about a *same-sex* friend or a *cross-sex* friend. During adolescence and young adulthood, most males and females report that they have one or more friends of the other sex (although they tend to have more same-sex friends than cross-sex friends). Thus, a thorough discussion of friendship must at least touch upon the complicated dynamics of cross-sex friendships and how they compare and contrast with same-sex friendships.

In the most fundamental ways, same-sex friendships and cross-sex friendships are similar. Both forms of friendship involve voluntary interdependence. And, when young adults report on their most common experiences with a close same-sex or cross-sex friend, nominations related to companionship, help, and support, and having someone to talk to are mentioned frequently for both

forms of friendship. Same-sex and cross-sex friendships do, however, differ in some of the rewards they offer and costs they entail. For example, in heterosexual samples, one of the most prominent benefits of cross-sex friendships for young adults is gaining an insider perspective about the opposite sex. Another common finding is that sexual attraction and sexual tension can operate—albeit frequently at low levels—in some cross-sex friendships. In one study, more than one-half of college students reported that they had had sex with a cross-sex friend at some point in their lives. Friends differ in the degree to which they perceive sexual undertones operating in their friendship, as well as in the degree to which they perceive it as adding spice to the relationship (for example, by affirming one's desirability as a romantic partner) or complicating it (for example, if sexual attraction is not mutual). Perhaps it is not surprising, then, that although individuals value intimate disclosure in both their same-sex and cross-sex friendships, they are more likely to avoid talking about certain topics, such as sexual and dating experiences, with their cross-sex friends than with their same-sex friends. Young adults also are more likely to deceive their cross-sex friends than their same-sex friends about their current romantic relationship involvement and whether or not they have feelings of romantic attraction toward their friend. Individuals who are simultaneously involved in a romantic relationship and cross-sex friendships report that their cross-sex friends and romantic partners alike may experience jealousy.

Same-sex friendships also provide unique benefits and pose unique challenges. Young adults devote substantial effort to maintaining their same-sex friendships, by offering the benefits that friendships should provide—such as companionship and emotional and task support. Some of the primary benefits of same-sex friendship, then, are also the primary costs. In other words, young adults perceive the time and effort they devote to their same-sex friendships as both a benefit and a cost.

Same-sex friendships, like cross-sex friendships, are linked with romance and mating. In adolescence as well as young adulthood, same-sex friends spend a lot of their time talking about the other sex. That is, young men talk about women and young women talk about men (and relationships).

It is not uncommon for young adults to perceive their same-sex friends as relationship advisers and mate-seeking partners. Yet, at the same time, they also perceive them as rivals. In one sample of young adults, more than half reported that they had competed with a same-sex friend to attract a member of the opposite sex. They perceived such competition as one of the most costly aspects of their same-sex friendship. Perhaps by befriending those who are similar to ourselves in values, activity preferences, and physical attractiveness, people fall into friendships with those who can both facilitate and interfere with their mating desires.

Gender Differences in Friendship

In many ways, men and women have similar perceptions of their friendships and similar friendship experiences. For example, both sexes value close friendships and intimacy in those friendships. Both sexes maintain close friendships that endure for many years. Men and women hold similarly high levels of trust in their friends, report similar unwillingness to confront their friends when something hurtful is said, and maintain similarly frequent contact with their friends. In young adulthood, men and women both spend a lot of time with their friends—in some cases, 10 to 25 hours per week. Despite the similarities, however, there also are some striking differences between men and women.

Gender differences in *same-sex* friendships are largest in the domains of activity and self-disclosure. More than anything else, women enjoy talking with their same-sex friends. Other activities—such as shopping, canoeing, or knitting—are preferred to the extent that they also allow for conversation. Men, in contrast, emphasize activities over talking. When men and women engage in conversation with their same-sex friends, women's self-disclosures include more personal and emotional information, and they tend to talk about their relationships and other people; men's conversations involve less personal information and more talk of sports and shared activities such as drinking. In essence, women's same-sex friendships tend to be more oriented toward personal sharing, and men's same-sex friendships tend to be more oriented toward joint activities.

Men's lower level of intimate self-disclosure in their same-sex friendships, relative to women's, does not necessarily imply that men are less capable of intimacy. In fact, men engage in more intimate self-disclosure in their cross-sex friendships than in their same-sex friendships (and more disclosure in their cross-sex friendships than women do). Thus, research suggests that men are capable of experiencing intimacy but either cannot or choose not to in their same-sex friendships. Men's intimacy needs appear to be met in their other relationships, including their cross-sex friendships and romantic relationships.

The most consistent sex differences in cross-sex friendship have been documented in the domain of sexual attraction. Although overall levels of sexual attraction to cross-sex friends are not high, men report greater sexual attraction to their cross-sex friends than do women. Men also overestimate the degree to which their friends are attracted to them and perceive sexual attractiveness as a more desirable characteristic for a cross-sex friend to possess. There are two primary, but nonmutually exclusive, explanations for this. One possibility is that men are socialized by the media, and pressured by their peers, to sexualize women. Conversely, evolutionary models of human behavior propose that men may have evolved to perceive reproductive-age women (who are not perceived as genetic kin) as potential sexual partners. It is likely that both causal forces are operating.

Friendship Conflict and Dissolution

Friendships are not without conflict. Sources of conflict are tied to the rules of friendship, characteristics involved in friendship formation and development of closeness, and the costs and benefits of friendship. For example, a primary benefit of friendship is self-disclosure, with increasing degrees of self-disclosure linked with increasing friendship closeness. One rule of friendship is that those disclosures are kept between friends; when that rule is broken, a friend has been betrayed and dissolution may result. A betrayal is one of several painful reasons for friendship dissolution, which also include nagging and criticizing, not confiding, jealousy, and not helping when needed. Young adults report that most of their friendships end

because of physical separation from a friend, acquisition of new friends, betrayal by a friend, or establishment by self or friend of a romantic relationship. Romantic relationships tend to interfere more with women's same-sex friendships than with men's same-sex friendships. Perhaps the lower level of emotional intimacy and greater level of specific shared activities in men's same-sex friendships allows them to more easily invest simultaneously in same-sex friendships and romantic relationships.

FRIENDS WITH BENEFITS

We all know that friendships between men and women differ from heterosexual romantic relationships. To give one example, sexual interaction typically occurs in close, intimate, romantic relationships whereas friends generally eschew these encounters. The boundaries between friendships and romantic relationships, however, are not as rigid as some may think. For example, one of the challenges facing some close cross-sex friends is sexual or physical attraction. Moreover, modern sexual interactions between heterosexual men and women differ dramatically from a half-century ago. One recent example of this change, noted primarily on college campuses, is the topic of this entry: *Friends With Benefits*. Put simply, friends with benefits relationships (FWBRs) represent a relational hybrid of friendships and sexual partnerships. More formally, FWBRs are platonic friendships (i.e., partners who are not dating and do not consider themselves to be romantically involved) in which individuals engage in some degree of sexual interaction. The sexual activity generally occurs on repeated occasions (in contrast to a one-night-stand or hookup), and can include behaviors ranging from kissing to sexual intercourse. This entry discusses the nature of FWBRs, how their ideal differs from their reality, and the variety of these relationship types.

Friends with benefits relationships attempt to combine the best of two relational worlds by fusing the communication and closeness of a friendship with the sexual intimacy of a romantic relationship. At the same time, however, partners try to avoid the commitments and responsibilities (the “strings”) typical of a romantic entanglement. In addition to lacking commitment, FWBRs typically lack exclusivity so that if partners wanted to date or engage in casual sex with other partners, they are generally free to do so.

Friends With Benefits: The Ideal Versus the Real

The ideal FWBR is simple: sex between friends. College students typically use the phrase “no strings attached” to describe this ideal FWBR form. Friends repeatedly engage in sexual behavior, but try to avoid anything that will make the partners feel tied down, such as commitment, exclusivity, and deeper emotional connections like romantic love or jealousy. Partners are free to have sex with each other, but can also investigate outside entanglements, romantic or otherwise.

In many cases, the reality of FWBRs is quite different from the ideal. It is relatively rare to find long-term FWBRs. There are several reasons why this might be the case. First, the FWBR label (though not necessarily the phenomenon) is relatively recent. (The FWBR label comes from the 1996 Alanis Morissette song titled *Head Over Feet*.) Given the relative rarity and recency of the relationship form, there are likely no cultural (or subcultural) scripts for FWBRs partners to follow. Second, managing a balance between a close sexual, but not romantic, friendship appears to be a difficult task. Contrary to the primary emotional commandment in FWBRs (i.e., “thou shalt not get attached”), it is typical that one partner develops feelings for the other. These feelings violate FWBRs’ primary emotional commandment and likely generate a fear, or actual instances, of unrequited love. Third, FWBR partners generally do not communicate about the relationship, its definition, or how to make it work. Friends with benefits relationships are likely difficult to maintain over time under the best of circumstances. A lack of explicit relational communication likely makes it nearly impossible.

Given the difference between the ideal and the real in FWBRs, it is not surprising that some partners maintain their FWBRs only so long as there is no other romantic option available to them. Some partners describe terminating their FWBR when they find a “real” romantic relationship that better serves their emotional needs. Despite the primary emotional commandment, finding a “real” relationship likely will not happen simultaneously for both partners, leading to hurt feelings by the “dumpee.” Another instance of hurt feelings might occur when one partner views the FWBR as

potentially romantic, a view that is not reciprocated by the other partner.

Variations in Friends With Benefits Relationships

Most discussions assume that FWBRs represent a single consistent relationship type. When college students were asked to describe their FWBR experience, however, a number of other relationship forms appeared under this label. The most popular FWBR form is the prototypical good friends who have sex with one another. At the opposite end of the spectrum, we see a second type involving serial hookups where partners appear to have relatively little interaction other than to arrange and engage in sexual encounters. Third, an intermediate position suggests that FWBRs are opportunistic. Partners who are members of the same social circle might not be particularly close, but can always rely on hooking up with each other if neither finds a different sexual partner by the end of the night.

The final two forms of FWBRs suggest that they are, in some cases, closely connected to romantic relationships. First, some partners meet, get to know each other, and form a FWBR as a means of testing the romantic waters. Conversely, in some cases, FWBRs represent the smoldering embers of a terminated relationship. That is, partners were previously romantically linked, terminated their relationship, however, miss (and, therefore, decided to continue) the sexual connection. Therefore, in some cases, FWBRs represent a transition *into* a romantic relationship, whereas in others, FWBRs represent a transition *out* of one.

In summary, it appears as though the term *friends with benefits* is used in a strategically ambiguous manner. The term communicates enough (i.e., two people are having sex but aren't dating or in a romantic relationship), without saying too much (i.e., doesn't communicate how close partners are, the frequency and nature of the sexual interaction, or the potential for a romantic relationship). Future research should investigate the various meanings associated with the FWBR label to gain a greater understanding of this difficult and complex relationship type. Future work could also explore the apparent disparity between

the ideal and the reality of FWBRs, and examine the ways that partners manage those dilemmas.

FUN IN RELATIONSHIPS

Having fun in relationships is an important motivation for individuals' entering into relationships and has consequences for closeness and attraction to partners. People establish and maintain relationships for a variety of reasons including security, companionship, and intimacy; relationships and romantic partners are also a source of fun and enjoyment. Actually, one of the primary goals of romantic interactions is to have fun, especially during early stages of relationship development. This entry discusses how partner and relationship characteristics, as well as the types of experiences couples have together, can increase the amount of fun in relationships.

Humor in Relationships

Fun is closely associated with humor in relationships. Humorous individuals are perceived as attractive, and sense of humor is an important

characteristic when selecting a romantic partner. Furthermore, in studies of preferences of partners' characteristics, sense of humor is rated as an increasingly important attribute as relationships become more serious (i.e., from friendships to short-term to long-term relationships). In particular, research on mate selection indicates that sense of humor is especially important for females when selecting a romantic partner, whereas males put less emphasis on humor relative to other characteristics, such as physical attractiveness. Humor has a significant function in relationships by promoting fun, enjoyable interactions, and intimacy. Furthermore, individuals in satisfying relationships report that humor occurs frequently and view humor as a central part of their relationships. Although humor is clearly a valued aspect of romantic relationships, it may be troublesome in cross-sex friendships because it can be interpreted as unwanted flirting or harassment.

Along with humor, other relationship characteristics may facilitate fun. For example, having fun in a relationship may be a function of the degree of similarity between partners. Research conducted by Brant Burleson and Wayne Denton indicates that people who are similar to their partners enjoy their interactions with partners more than do those who are dissimilar, and enjoyment of interactions is an important factor leading to attraction in relationships. In short, similarity promotes fun in relationships, and fun is associated with attraction.

Furthermore, relationship quality may be enhanced by playfulness between partners in more established relationships. People who engage in playful interactions in their relationships tend to experience more positive emotions, relationship satisfaction, and feel closer to their partners. Interestingly, playfulness can include mock aggression, or *play fighting*, between partners. Mock aggression occurs frequently in relationships and is generally reported as being associated with positivity in the relationship.

Fun and Self-Expansion

In the most general sense, people pursue relationships that are rewarding or that benefit them in some fashion. Fun and enjoyment are common rewards that relationships provide. Art and Elaine

Aron's *Self-Expansion Model* provides a theoretical basis for why fun would be particularly desirable in close relationships. According to the model, people are fundamentally motivated to enhance their capabilities through the accumulation of knowledge, experience, identities, and other resources. One way to accomplish this is through participation in self-expanding activities that involve novelty, challenge, fun, and enjoyment. The model further states that the primary way people satisfy this motivation is through close relationships. The Self-Expansion Model hypothesizes that initial romantic attraction is greatest for partners who provide the potential to maximize one's own expansion. Thus, engaging in novel activities with a partner should be experienced as fun and therefore enhance attraction for that partner and increase relationship satisfaction.

Research by Aron and colleagues has examined the association between fun activities and marital satisfaction. In their study, married couples initially rated a list of activities for how exciting or pleasant they found each activity. Couples were then randomly assigned to either engage in exciting and fun activities or pleasant activities, or did not engage in special activities over the following weeks. Exciting and fun activities included activities such as skiing, dancing, and hiking. In contrast, pleasant activities were generally less fun and included activities such as visiting friends, seeing a movie, and eating out. Those in the no special activity condition were from the waiting list. Results indicate that relationship satisfaction 10 weeks later was greater for those who engaged in the fun and exciting activities compared with the pleasant activities or those who did not engage in any special activities. These results suggest that having fun is important for marital satisfaction.

Other studies by Aron and colleagues investigated the role of novel, challenging, and arousing experiences on self-expansion. A series of laboratory experiments tested whether these types of fun experiences enhanced relationship quality. In these experiments, married couples first completed some questionnaires, participated together in a task, and then completed more questionnaires. The questionnaires before and after the task served as a pretest and posttest measures of experienced relationship quality. The task was experimentally manipulated so that couples in the experimental

condition engaged in an activity that was novel, challenging, and arousing and those in the control condition took part in a less novel, less challenging, and less arousing activity. In the experimental condition, the couple was tied together on one side at the wrists and ankles and then took part in a task in which they crawled together on mats for 12 meters, climbing over a barrier at one point, while carrying a foam cylinder with their heads and bodies. In the control condition, one partner slowly crawled to the middle of the mat and back, then the other partner did the same, then the first partner repeated this, and so on. The first study employing this paradigm found a significantly greater increase in experienced relationship quality for couples in the experimental (novel/challenging/arousing) condition compared with the control condition. Additional studies revealed parallel findings when a no-activity condition was included, and when relationship quality was measured based on videotaped interactions between members of the couple. These results suggest that engaging in fun activities (in this case, activity that is also novel, challenging, and arousing) leads to increases in relationship quality.

The Self-Expansion Model suggests that fun experiences would be beneficial because they add to one's self-concept and promote closeness. The influence of humorous experiences on closeness has been examined. Participants in this study were pairs of strangers randomly assigned to humorous tasks (e.g., blindfolded dance steps) or a no-humor

condition (e.g., dance steps without a blindfold). As predicted, participants completing the humorous tasks felt closer to one another, with these results being produced by the experience of self-expansion with the partner.

G

GAIN-LOSS THEORY OF ATTRACTION

The Gain-Loss Theory or model of interpersonal attraction is concerned with the effect that a sequence of positive, negative, or positive and negative evaluations about a person may have about that person's attraction to the person or persons making those evaluations. For example, when giving feedback to individuals on how they have performed on a task, is it better to start with what they have done well or what they need to improve? The model was first proposed in 1965 by Elliot Aronson and Darwyn Linder and was the subject of a relatively small number of studies carried out in the late 1960s and early 1970s. This entry defines the gain-loss effect in attraction and provides five explanations for its occurrence.

The model proposes that a change in evaluation (i.e., a gain or a loss) has a greater effect on a person's attraction toward the evaluator than does no change in evaluation (i.e., all positive or all negative). More specifically, the model states that a change in a sequence of evaluations of a person from negative to positive (i.e., a gain or $- +$) may be more rewarding to that person than a series of uniformly positive evaluations (i.e., all positive or $+ +$). Similarly, a change in a series of evaluations of a person from positive to negative (i.e., a loss or $+ -$) may be more punishing than a sequence of similarly negative evaluations (i.e., all negative or $- -$). Stated in this way, the model applies

primarily to the way a person feels toward the evaluator, although the gain-loss phenomenon is likely to also affect how the person feels about him or herself. The model itself does not explicitly say that the effect of these evaluations works through recipients' feelings about themselves. The most rewarding sequence is gain ($- +$), followed by all positive ($+ +$), all negative ($- -$) and loss ($+ -$). More support has been found for the gain effect than for the loss effect.

Five explanations have been put forward for gain-loss effects. Recipient anxiety or anxiety reduction is one of them. A negative evaluation is likely to bring about negative affect such as anxiety, hurt, and self-doubt. A subsequent positive evaluation is likely to reduce these negative feelings of anxiety. Consequently, recipients should feel more positively toward an evaluator who has reduced their anxiety than toward someone who has not made them anxious in the first place. Although it seems clear how this explanation may account for a gain effect, it is more difficult to see how it can be applied to a loss effect where a generally more negative evaluation should evoke greater anxiety.

A second explanation is an evaluation contrast one. Positive evaluations may seem more positive after negative evaluations than after positive ones. Similarly, negative evaluations may appear more negative after positive evaluations than after negative ones. This explanation implies that these effects should be less pronounced when a neutral evaluation is used because the contrast is less strong.

Evaluator discernment is a third explanation. Evaluators expressing uniformly positive or negative evaluations about another person are likely to be seen as being less discerning or discriminating by that person than will evaluators whose evaluations vary because the unvarying evaluations will be seen as being more a reflection of the evaluator than of the person being evaluated. A less discerning person may be seen as less attractive than a more discerning one. When evaluators change their evaluation, later evaluations are seen as being more carefully considered and accurate than earlier ones. Thus, later evaluations have greater effect.

A fourth explanation is a recipient competence one. The evaluation may affect how competent recipients feel and the way they subsequently behave. Recipients given a negative evaluation may feel less competent and may be motivated to make a more competent impression. Recipients receiving a positive evaluation after a negative one may feel that they have become more competent and that this increased competence has been recognized by the evaluator. Thus, they find the evaluator more attractive. Recipients obtaining a negative evaluation after a positive one may feel less competent than would those receiving a positive evaluation after a negative one because they have not had an opportunity to show how competent they are.

Evaluator flattery is a fifth explanation. Evaluators making all positive evaluations may be seen as trying more to flatter the recipient or to ingratiate themselves with the recipient than would evaluators who also make some negative evaluations that may be seen as trying to provide a more accurate evaluation. Evaluators who are seen as being flattering or ingratiating may be considered less attractive than are those who are seen as trying to be honest. This explanation has not been explicitly articulated to account for why a gain sequence may lead the recipient to see the evaluator as more attractive than a loss sequence. Presumably, the positive evaluations that follow negative ones may be perceived as a less strong attempt to flatter the recipient than all positive evaluations. It is not clear how this explanation could apply to accounting for a loss effect. Evaluators making negative evaluations after positive ones may be seen as trying to be more accurate than evaluators making positive evaluations followed by negative ones. Consequently, loss evaluators should be viewed as more positive

than gain evaluators but this effect has not been found. This explanation has not been considered a viable one for studies in which recipients were led to believe that the evaluator was not aware that her or his evaluations were being received by the recipients. In other words, in this situation there was little reason for recipients to believe that the evaluator was trying to flatter them.

Despite the relatively limited research on Gain-Loss Theory, this topic remains an important one particularly in everyday situations where positive feedback needs to be tempered with negative feedback.

GAY, LESBIAN, AND BISexual RELATIONSHIPS

Intimate same-sex relationships have existed throughout history and in places across the globe. This entry presents scientific knowledge about gay and lesbian relationships in contemporary society. Although the relationships of bisexuals are not well understood, key findings are highlighted. A notable limitation of current knowledge is that most research has been conducted in the United States with primarily White, middle-class people.

About 1 percent of adult women self-identify as lesbian and 2 percent of adult men self-identify as gay. Many of these individuals have an intimate relationship. In an illustrative project, demographers Christopher Carpenter and Gary J. Gates analyzed representative surveys and census data from California. They estimated that about 40 percent of gay men and more than 50 percent of lesbians age 18 to 59 are currently living with a same-sex partner. In comparison, about 60 percent of heterosexuals age 18 to 59 are currently living with an other-sex partner. At the time of this study, same-sex couples in California could register as domestic partners with rights and responsibilities similar to those of married heterosexuals. Carpenter and Gates found that almost half of cohabiting lesbians are registered as domestic partners, compared with less than a quarter of cohabiting gay men. U.S. Census data show that gay and lesbian couples can be found in all parts of the country.

The experiences of same-sex couples in the United States are influenced by the social stigma of homosexuality. Although social attitudes are becoming more tolerant, many gay and lesbian individuals and couples report incidents of social rejection, prejudice, and discrimination. In national polls, only half of Americans say that same-sex couples should be allowed to form legally recognized civil unions or domestic partnerships. The topic of same-sex marriage continues to be a source of heated controversy.

Despite the differing social contexts for same-sex and heterosexual relationships, there are many commonalities in the close romantic relationships of lesbian, gay, bisexual, and heterosexual individuals. Human needs for intimacy and the capacity to form strong emotional attachments affect all of us. Most adults want to have a committed love relationship, and lesbians and gay men are no exception. In one national survey, three of four lesbians and gay men said that if same-sex marriage were legal, they would like to get married at some time in their lives. Whatever their sexual orientation, most individuals seek similar qualities in a romantic partner, including affection, dependability, shared interests, and similarity of religious beliefs.

Relationship Satisfaction

Researchers have compared gay, lesbian, and heterosexual couples using standard measures of

love, intimacy, and relationship satisfaction. The consistent finding is that same-sex couples do not differ significantly from heterosexual couples on these measures. This does not mean, of course, that all same-sex couples have satisfying relationships but, rather, that lesbian and gay couples are no more likely to have good—or bad—relationships than are their heterosexual peers.

Further, the factors that enhance or detract from satisfaction in same-sex and heterosexual relationships are similar. For example, regardless of sexual orientation, relationship quality is greater when partners trust each other and have effective communication skills. On average, same-sex and heterosexual couples do not differ on these predictors of relationship quality. Relationships also benefit when partners receive support from people in their social network. The support experiences of same-sex and heterosexual couples do sometimes differ. When asked to name the individuals who provide them with help, advice, and emotional support, lesbians and gay men are more likely than heterosexuals to name friends and less likely to mention family members as support providers. On balance, however, same-sex and heterosexual couples usually receive comparable levels of social support, but from different sources.

No relationship escapes at least occasional disagreement or conflict. Lesbian, gay, and heterosexual couples generally report disagreeing about similar topics, with finances, affection, sex, criticism, and household tasks heading the list. They also report arguing with similar frequency. Same-sex couples face some unique problems, however, such as whether to disclose their sexual orientation or the intimate nature of their relationship to other people. Another central issue is how successfully partners are able to solve problems that arise in their relationship. Both self-report surveys and studies observing couples in laboratory settings indicate that lesbians and gay men are at least as good as heterosexuals in solving relationship problems.

Sexuality

In general, gay and lesbian partners report levels of sexual satisfaction comparable with those of heterosexuals. Greater sexual satisfaction is usually associated with greater overall relationship satisfaction. There is wide variability in sexual

frequency and a general decline in frequency the longer a couple is together. On average, lesbian couples report having sex less often than either heterosexual or gay male couples. Early in a relationship, gay male couples have sex more often than other couples do. The reasons for these differences in reports of sexual frequency are not well understood. Some speculate that gender socialization leads women to repress sexual feelings, to have difficulty initiating sex with a partner, or to define sexuality differently than men do. Others suggest that men are generally more interested in sex than women, leading to more frequent sexual activity in a couple with at least one male partner.

A consistent finding is that gay men differ from both lesbian and heterosexual couples in their attitudes and behavior about sexual exclusiveness. Data from the large American Couples study conducted by Philip Blumstein and Pepper Schwartz are illustrative. Only 36 percent of gay men said it was important to them to have a sexually monogamous relationship, compared with 71 percent of lesbians, 75 percent of heterosexual husbands, and 84 percent of wives. In actual behavior, only a minority of lesbians (28 percent), husbands (26 percent), and wives (21 percent) had engaged in sex outside their primary relationship, compared with 82 percent of gay men. Sexual fidelity is positively related to relationship satisfaction for lesbian and heterosexual couples, but not for gay male couples. One reason is that some gay male couples have agreements permitting sex outside their primary relationship.

Gender Roles

Western societies have traditionally defined heterosexual marriage as having distinct gender roles: the husband is the head of household, economic provider, and chief decision maker, and the wife is the homemaker and follower. It is often assumed that same-sex couples adopt similar husband-wife roles as a model for their relationships. Actually, most contemporary lesbians and gay men reject these roles.

Most gay men and lesbians are in dual-earner relationships. Both partners are employed, and neither is the exclusive breadwinner. When same-sex

couples live together, the most common division of household work involves flexibility, with partners sharing domestic activities or dividing tasks according to personal preferences. Although the equal sharing of household labor is not inevitable in same-sex couples, it is more common than among heterosexuals. Lesbians and gay men generally favor power equality in their relationships. Not all couples achieve this ideal, however. In summary, research shows that most contemporary lesbians and gay men avoid husband and wife roles, instead constructing a more egalitarian pattern of shared responsibilities and decision making.

Creating Enduring Relationships

Many same-sex couples desire long-lasting relationships. How successful are lesbians and gay men in attaining this goal? This question is difficult to answer with precision. Public records of heterosexual marriage and divorce provide standard estimates about marital stability over time. For same-sex couples, comparable records do not exist. Several studies have documented the experiences of gay and lesbian couples who have been together for 20 years or longer. The recent analyses of representative data from California by Carpenter and Gates found that gay men currently living with a same-sex partner had been together for an average of 10 years; gay men who had registered as domestic partners had been together for 12 years. Lesbians' relationships were slightly shorter: 8 years for women living with a partner and 9 years for women who had registered as domestic partners. On average, these gay men and lesbians were in their early 40s, indicating that they had spent a substantial proportion of their adult lives with their current partner.

Another approach to understanding the longevity of same-sex relationships is to conduct studies that follow couples over time. Lawrence A. Kurdek compared gay and lesbian couples with married heterosexual couples with and without children. During more than 10 years, the breakup rates for same-sex and heterosexual couples without children were similar: about 1 in 5 couples ended their relationship. In contrast, married heterosexuals with children had a substantially lower breakup rate of only 3 percent. In these comparisons,

relationship stability was affected by the presence of children, rather than by the partners' sexual orientation.

To understand why there may be differences in the longevity of same-sex and heterosexual relationships, it is helpful to consider factors affecting partners' commitment to their relationship. First, positive attractions such as love and intimacy make individuals want to maintain a relationship. Second, the availability of attractive alternatives to the current relationship, including other possible partners or the prospect of being alone, reduces commitment. Third, barriers to leaving a relationship are important. Barriers include investments that increase the emotional or financial costs of ending a relationship, as well as moral or religious feelings of obligation to one's partner. Research shows that these same factors affect commitment in both same-sex and heterosexual relationships. One difference is noteworthy, however. Gay and lesbian couples consistently report fewer barriers to ending a relationship than do heterosexual married couples. Same-sex couples are less likely to own joint property or have children together. In contrast to married heterosexuals who must pay for and go through a legal divorce, most gay and lesbian couples do not need legal proceedings to end their relationship. It is possible that as legal and social recognition for same-sex relationships increases and more same-sex couples become parents, the barriers to ending same-sex relationships will become more similar to those of married couples.

Couples' Counseling

When relationship problems arise, couples sometimes seek the aid of a counselor. Although many issues are common among all types of romantic relationships, therapists who work with lesbian, gay, and bisexual clients should be knowledgeable about the unique issues these clients may face. In 2000, the American Psychological Association adopted "Guidelines for Psychotherapy with Lesbian, Gay, and Bisexual Clients," designed to improve the education of mental health professionals and the quality of the services they provide.

Some therapists adopt approaches to therapy that affirm the value and legitimacy of gay, lesbian, and bisexual lifestyles. These affirmative therapies

emphasize the potential impact of societal prejudice and acknowledge the importance of same-sex relationships. Although many gay affirmative therapists are themselves gay or lesbian, an affirmative approach can be used by therapists regardless of their own sexual orientation.

Relationship Dissolution

When people are asked why a recent romantic relationship ended, gay, lesbian, and heterosexual partners mention similar problems. These include a partner's frequent absence, sexual incompatibility, mental cruelty, and lack of love. Other common reasons are a partner's nonresponsiveness (e.g., poor communication or lack of support from the partner), a partner's personal problems (e.g., an alcohol problem), or sexual issues (e.g., the partner had an affair).

The ending of a serious romantic relationship is often difficult. When asked to describe their emotional reactions to ending a recent same-sex relationship, lesbians and gay men describe similar emotions. Emotional reactions to a breakup differ for the partner who initiated the breakup (who may feel guilt but also relief and happiness) and the partner who was left behind (who may feel lonely, angry, and helpless). The reasons for the breakup may also make a difference.

After a relationship ends, former partners may experience such problems as financial stress, deciding on the nature of their continuing relationship with the ex-partner, and difficulties finding a new partner. Although partners' reactions to the ending of same-sex and heterosexual relationships are generally similar, there may also be distinctive issues for lesbians and gay men. For example, because gay male and lesbian communities are often small, there may be pressure for same-sex ex-lovers to handle breakups tactfully and to remain friends.

The death of a loved partner is often traumatic, and the emotional aftermath of bereavement appears to be similar for surviving partners whatever their sexual orientation. However, the social context of bereavement often differs for same-sex and heterosexual partners. Gay and lesbian survivors may receive less social support for their loss, especially if they have concealed the nature of their

relationship from family or friends. The lack of legal protection of the rights of same-sex couples can also pose problems. Under U.S. federal law, a gay or lesbian surviving partner is not eligible for spousal benefits from Social Security or the Veterans' Administration. Without wills or other legal documents, the survivor may have no claim to the estate of a long-term partner that they contributed to building. If children are involved, there may also be issues about child custody. For gay men, the effects of the AIDS epidemic have been devastating. The social stigma surrounding AIDS can heighten the difficulties of bereavement for the survivor.

Relationships of Bisexual Men and Women

Some individuals are attracted to both men and women. What are their romantic relationships like? A problem in answering this question is that the term *bisexual* is used in several distinct ways. One approach focuses on individuals who self-identify as bisexual, in contrast with those who identify as gay, lesbian, or heterosexual. Another approach characterizes a person as bisexual if his or her lifetime history of sexual behavior includes partners of both sexes. In a recent U.S. national survey, only 0.8 percent of adult men self-identified as bisexual, although 4 percent said they had had sex with both male and female partners since age 18. Similarly, only 0.5 percent of women identified as bisexual, but 3.7 percent had had sex with both male and female partners since age 18. Personal identity and behavior do not always correspond. Consequently, understanding the relationships of bisexuals requires studies that focus on specific subgroups of individuals who differ in their patterns of bisexual identity and behavior. Although there are many anecdotal accounts about the relationships of bisexuals, scientific research is extremely limited.

In the 1980s, Martin S. Weinberg and his colleagues interviewed self-identified bisexuals in San Francisco. Most of these White, college-educated individuals were permissive in their sexual attitudes. This and other studies permit a few generalizations about the relationships of self-identified bisexuals. Most bisexuals who are in a primary relationship have a partner of the other sex, and

some are legally married. Most bisexuals have partners identify as heterosexual, lesbian, or gay, rather than as bisexual. This can create relationship problems. Some heterosexual partners may view bisexuality as a sign of immaturity, indecisiveness, or promiscuity. Lesbians and gay men may also have negative stereotypes about bisexuals, believing that they are denying their true homosexual orientation or that bisexuals are likely to desert a same-sex partner for a heterosexual one. The extent to which bisexuals' experiences of satisfaction, conflict, and commitment differ depending on the gender and sexual identity of their partner is not known.

Another focus of research has been the experiences of teenagers and young adults who are developing their sexual identity and relationship preferences. A large-scale survey of more than 20,000 U.S. adolescents found that 3.9 percent of girls and 6.3 percent of boys reported romantic attractions to both males and females. Longitudinal studies have documented that some young people change their sexual identity and behavior over time, a pattern that has been termed *sexual fluidity*. Research by Lisa M. Diamond is illustrative. She interviewed women age 18 to 25, all of whom identified as not being heterosexual. Some women initially identified as lesbian or bisexual; others said they were questioning their sexual identity or rejected labeling themselves. During a 10-year period, more than two-thirds of these women changed their sexual identity, for instance, shifting from questioning to lesbian or from bisexual to heterosexual. The reasons for identity change were varied and included changes in whom the women were dating and pressure from friends or partners about their sexual identity. Research suggests that sexual fluidity is found among both women and men, but is more common for women.

Other patterns of bisexual behavior have also been studied. Many adults who currently identify as gay or lesbian have had heterosexual relationships in the past. Indeed, some individuals now in same-sex relationships were formerly in a heterosexual marriage and have children from that relationship. These individuals are typically included in research on same-sex relationships. In addition, some adults, typically men, identify strongly as heterosexual yet have casual sex with men. Public health researchers concerned with

sexually transmitted diseases often include these individuals in studies of men who have sex with men. Some social settings such as prison can lead individuals who view themselves as heterosexual to form romantic or sexual relationships with same-sex prison mates.

Conclusion

Scientific research on the relationships of lesbians, gay men, and bisexuals is growing. Many lesbians and gay men create satisfying, long-lasting relationships, even in the face of societal prejudice and discrimination. Although the social contexts for same-sex and heterosexual relationships differ, the internal processes affecting same-sex and heterosexual couples are remarkably similar. Limitations of available studies should be noted. Most research on the relationships of contemporary lesbians, gay men, and bisexuals has investigated the lives of White, middle-class Americans. Much less is known about the experiences of working-class or ethnic-minority couples in the United States or the experiences of individuals from other cultures.

GENDER-ROLE ATTITUDES

Gender-role attitudes are people's beliefs about the appropriate role-related behaviors for women and men and girls and boys. This entry focuses on the definition and measurement of gender-role attitudes. Research on correlates of gender-role attitudes are reviewed along with findings about how these attitudes relate directly to romantic and other relationships.

People described as having "traditional" gender-role attitudes believe that women should focus on being housewives and mothers, but men should have a job that supports their wives and children. Traditional gender-role attitudes are also associated with the idea that men, not women, should make important decisions and that men should behave in "masculine" ways whereas women should behave in "feminine" ways. Such attitudes are different from stereotypes. Gender stereotypes are beliefs about the *characteristics or nature* of men and women and boys and girls. Thus, the

belief that men are aggressive is a stereotype, but the belief that men *should* act aggressively would be a gender-role attitude. Related concepts include femininity and masculinity, which are based on stereotypes, but relate to one gender or the other. Femininity is a set of ideas about the nature of women and girls, whereas masculinity is a set of ideas about the nature of men and boys, based partly on stereotypes. Self-labels, that is, viewing the self as having masculine or feminine characteristics, are often a focus of gender-related research.

Measuring Gender-Role Attitudes

Several widely used scales assess gender-role attitudes. Each of these scales measures slightly different aspects of gender-role attitudes. The scale most often used by researchers is the Attitudes Toward Women Scale (AWS), originally published by Janet Spence and Robert Helmreich in 1972. This scale measures agreement with the traditional division of labor, with women being housewives (sample items: “It is ridiculous for a woman to drive a truck and for a man to dust furniture” or “Women should worry less about their rights and more about becoming good wives and mothers”) and men being supported in their roles as workers (a sample reverse coded item is, “There should be a strict merit system in job appointment and promotion without regard to sex”). Other items include these: Telling dirty jokes should be mostly a masculine prerogative, the initiative in dating should come from a man, and the husband has in general no obligation to inform his wife of his financial plans. Other items include that a woman should not expect to go to exactly the same places or to have quite the same freedom of action as a man. Thus, the emphasis is on male dominance in relationships. A person who agrees with these traditional attitudes is labeled as “sexist” by researchers using this scale. Those who disagree with these ideas and prefer that women and men be treated equally in the workplace and believe that women should have equal rights with men in the home are labeled as egalitarian or nonsexist. Although the original version had 55 items, most researchers prefer to use a briefer 15-item version of the AWS.

Many newer scales have been published, but none has been widely used. In selecting an appropriate

scale for measuring gender-role attitudes, it is important to assess exactly what the scale is measuring. The AWS focuses on views of equality for women and men in the workplace and of division of household labor. A few items assess interpersonal communication or other aspects of relationships. Issues such as the acceptability of men engaging in nontraditional activities outside the workplace are not addressed, nor is general positivity toward women or men.

In the mid-1990s, Peter Glick and Susan Fiske argued for a reconceptualization of sexism, or gender-role attitudes. As they pointed out, traditional gender-role attitudes contain two different components. First, there is a hostility toward nontraditional women. Second, there is what Glick and Fiske labeled as *benevolent sexism*, where men are seen as appropriately dominant over weaker women and where men are expected to take care of women. These two dimensions are included in their Ambivalent Sexism Inventory (ASI). This scale is more explicitly concerned with relations between women and men and largely ignores ideas about roles and rights of women (which is the primary focus of the AWS). The 11-item Hostile Sexism Scale includes items such as, “Most women interpret innocent remarks or acts as being sexist,” and “Women seek to gain power by getting control over men.” The 11-item Benevolent Sexism Scale includes items such as, “Women should be cherished and protected by men,” and “Women, compared with men, tend to have a superior moral sensitivity.” The ASI measures something different than the AWS, but the scores tend to be highly correlated. The ASI is widely used by researchers today. Extensions of the ASI have included scales measuring hostility and benevolence toward traditional men.

A question of much interest to researchers is how gender-role attitudes differ among groups and whether they have changed over time. Because of its continuing popularity, it is possible to compare AWS scores obtained in the United States during the different decades in the latter part of the 20th century and into the 21st century. Such studies have shown a continuing trend for U.S. adults and college students to be *less* in favor of strong role divisions for women and men over time. Recent studies of college students using the AWS show high levels of egalitarianism. Despite this floor effect of low traditionality, AWS scores still show

some variability and show consistent relationships with other variables, as discussed later.

Unfortunately, these scales measuring gender-role attitudes are focused on the United States. Researchers have used scales such as the AWS or ASI in other cultures, but generally find that at least some of the items have to be omitted because of their lack of applicability in other cultures. Because of language differences as well as cultural differences, it is difficult to compare scores directly across cultures. However, attempts to do this generally show gender-role attitudes in the United States as less traditional than are those from other cultures. Others have attempted to develop parallel scales for other cultures, such as the Islamic Attitudes Toward Women Scale developed for Muslim cultures. This scale builds on the AWS and incorporates some of its items. New items include beliefs about the acceptability of women consenting to marriage, negotiating marriage contracts, clothing covering the body, veiling, and seclusion of women—issues of direct relevance to Muslim societies today. A study comparing scores on this scale of Pakistani immigrants in the United States indicated that those who had been in the United States longer were less traditional than were newer immigrants.

Correlates of Gender-Role Attitudes

Studies using scales such as the AWS have indicated that men support traditional gender roles more than women do. This can be seen in studies using the AWS, as well as in other measures, in college student samples, and in other samples. However, this pattern of men being more in support of traditional gender roles is not always seen in other cultures. For example, recent work indicates that women may be more supportive of benevolent sexism than are men in countries with high levels of gender inequality. Consistent with the finding of changes toward more egalitarian attitudes during the last half of the 20th century in the United States, data also show that younger and more educated samples tend to have less traditional attitudes and fewer gender stereotypes.

What makes some people more traditional than others? Researchers have only a partial answer to this question. First, those more strongly identified

with traditional religions tend to hold less egalitarian attitudes, being more in support of the traditional division of labor between women and men. Judaism, Christianity and Islam all place a strong emphasis on women's roles as mothers, so it is not surprising that those who attend religious services and receive more exposure to these ideas tend to be more traditional in their gender-role attitudes.

In addition, there is an effect of role modeling. Children growing up in families where their mother is employed outside the home tend to have less traditional attitudes.

The authors of the ASI suggest that high scores on the Hostile Sexism Scale are found in men who desire power over women and who may be likely to sexually harass women.

Relationship Issues and Gender-Role Attitudes

Beliefs about appropriate gender-role behaviors for women and men affect relationships in various ways. For example, people who believe in gender equality might have different expectations than might people with traditional gender-role attitudes about whether or not household labor should be shared. Expectations about childcare may also be directly affected. That women generally are more favorable toward gender equity but men have more traditional gender-role attitudes may create disagreements as couples develop their lives together and make basic decisions about employment and taking care of the home. Although in most households, women still perform most of the household labor, research has shown that husbands and wives who divide household labor more equally tend to be more satisfied with their marriages than are those who adhere to a strict traditional division of labor.

Acceptance of traditional gender-role attitudes may result in other strains to relationships as well. Traditional men and women experience more jealousy in their romantic relationships than do egalitarian men and women. Men who hold traditional gender-role attitudes are also more likely to engage in coercive sexual activities and are more accepting of a husband assaulting his wife than are egalitarian men. Thus, rather than complementing one another, traditional attitudes may put men and women at odds with each other, reducing relationship satisfaction, and creating strains on the

relationship. Another consistent finding is that gender-role attitudes affect choices of activities, especially in children. Those with the most traditional attitudes interact primarily with those of the same gender in their leisure activities.

GENDER ROLES IN RELATIONSHIPS

Gender roles are sex-specific, reciprocal claims and obligations. Because women and men move in many contexts and kinds of relationships, they occupy many roles. Understanding how gender roles shape behavior in relationships involves distinguishing between sex—biological differences between males and females—and gender—the cultural distinctions that people draw between masculinity and femininity. Gender is not a biological given, but is what people collectively agree that sex attributes mean. Men and women are expected to perform in ways consistent with these cultural ideals, and gender is taught and rehearsed daily throughout life. Though people may not always live up to the obligations specified by (or implicit in) gender roles, accountability to those ideals shapes behavior nonetheless.

Gender roles are sets of connected behaviors that are expected of men and women in specific contexts (such as family homes or public places of work). These expectations are upheld by ideologies (collective systems of beliefs about right and wrong) that legitimate these roles. For instance, many Western societies assign women most care work within family homes (gender role), on the shared understanding that they are more nurturing by nature (ideology). People give little girls dolls and boys trucks; girls and boys then develop different skills appropriate for jobs of different status, which people take as signs of natural differences, thereby justifying their gender roles within families. These gender roles are associated, in turn, with relative advantages and disadvantages. For example, men’s abilities to work for pay relatively unfettered by family care allow them to acquire greater status and wealth; women’s positions and well-being are thus often dependent upon men’s. In this sense, men’s privileges are intimately tied to women’s disadvantages, and none of this depends on individuals’ intentions. People reproduce gender inequality without necessarily meaning to do so.

Drawing on this understanding of gender and institutional contexts, this entry explores gender roles within three common relationships: romantic, family, and friendships.

Romantic Relationships

Women’s roles typically involve labor performed in the service of others, including care work and attending to the emotions of others. Researchers find that women prioritize the sexual and other needs of male dates more than vice versa, a finding that dovetails with research on communicative exchange that documents men’s conversational dominance and women’s greater deference. Further, men are more likely to decode women’s nonverbal cues as being sexual in nature and to interpret women’s friendliness as sexual interest.

Men, more than women, use physical attractiveness to select dating partners. Although traditional roles specify that men initiate dates, research indicates that, at least in Western society, women are more likely to ask men out than in the past and are more likely to want to share the expenses of the

date. Studies also show that men are more likely to view these women as more sexually interested than women who follow traditional dating protocols.

Whereas research suggests that men and women hold certain different attitudes and beliefs about romantic relationships, such differences are often exaggerated in the popular press and do not hold across cultures. Thus, research comparing men and women in the United States and China finds that culture explained more variation in beliefs about love and romantic relationships than did gender. And within the United States, race, ethnicity, and class differences are often as predictive of differences as is gender. That said, within the United States, most recent studies on romantic ideology find little or no gender differences. Large numbers of both men and women are likely to insist that love be the basis for marriage; not quite as high a proportion believe love is necessary for marriage maintenance. Despite these similarities, compared with women, men are more likely to say that they would be willing to marry without love, and they are less likely to view emotional satisfaction as important to marriage maintenance.

Sexual satisfaction is related to overall relationship satisfaction, whether among married, heterosexual couples or among gay men and lesbians in committed relationships, and gender roles play a role in shaping sexual intimacy. For instance, among single persons, wishing to nurture a partner, emotionally valuing a partner, and experiencing pleasure motivates coitus among men and women alike, but valuing a partner emotionally motivates women to engage in intercourse more so than it does men; women remain less accepting of casual sex. Similarly, research on “hooking up” among college students reveals that the prevalence of such activity does not signal gender equality in relationships. Men still initiate such activity, men’s sexual pleasure appears to be prioritized (as they are far more likely than are women to reach orgasm), and women remain more likely to gain bad reputations for having multiple sexual partners.

Despite their different gender roles, men and women have some similar expectations of intimate relationships. A sense of equity is important for both, and greater equality between men and women fosters healthier relationships for women and greater relationship stability and sexual satisfaction for men. Men who hold traditional masculine

ideologies report lower relationship quality, whether they are engaged in heterosexual or gay relationships; women who hold traditional feminine ideologies also report lower relationship quality.

Family and the Division of Labor

Historical and cross-cultural evidence suggest that there are no universals in the tasks that fathers and mothers perform apart from the earliest infant care and breastfeeding. Economic and structural changes have had enormous impact on both men’s and women’s access to social resources and subsequent gender relations within families. For instance, in the United States, industrialization and the 19th-century transition away from an agricultural, family-based economy changed the ways that men and women related to social institutions and to one another. Within the family-based economy, women, men, and children had worked together; both parents took responsibility for childrearing. The change to a market economy pulled men into paid employment outside the home; women were relegated to the domestic realm of unpaid work, which became devalued, given the premium placed on money in the new economy. Gender-role expectations altered such that middle-class fathers shifted from interacting with and teaching children, to providing financially for families (the “good provider”), and the home became a child-centered haven of mothers’ (the “homemaker”) responsibility, even though race and class relations precluded many men and women from living up to these idealized gender roles.

This “separate spheres” mentality of paid work for men and the domestic realm for women has been disrupted by economic changes from the 1970s on that created both a greater need and wider opportunities for women’s paid labor. Dual-earner households have become more prevalent, and men and women, married and single, are expressing more egalitarian gender-role expectations than in the past. Married men and women express desires to share equal responsibility for decision making, childrearing, and household chores, although for the most part, men’s behavior has lagged behind these expectations. Further, the ability to balance work and family varies by race and class.

According to the current construction of gender roles in U.S. families, women are expected to provide the bulk of caregiving at all stages of the life course. For instance, the motherhood role demands that women be the primary caregiver to children, even women who work full time, and the less-involved style of parenting for fathers has persisted well past the demise of the normative marital combination of breadwinner and homemaker. However, recent research finds that fathers within two-parent households have increased their interaction with and responsibility for children, though they still lag behind mothers' labor, and their contribution rises in relation to increases in education, income, number of hours worked by their wives, and propensity toward egalitarian attitudes. Fathers who spend more time with their children express greater satisfaction with their marriages, community, and family ties and report overall higher life satisfaction. The degree of involvement, however, varies by race; Hispanic fathers spend more time with their children on the weekends than White fathers do, followed by African-American fathers.

Change in gender roles concerning household labor has lagged even further, giving rise to the notion that women experience a "second shift," including primary responsibility for domestic labor; this unpaid work commences when they conclude their paid work. Gender relations are apparent in the consistent finding that husbands, but not wives, gender-role attitudes influence the distribution of household labor. Further, these ideologies vary by race and class. For instance, White men with higher levels of education are more likely to have attitudes that support women who deviate from traditional gender roles, such as working full-time. African-American men, who are more likely to have been raised in families wherein mothers worked for pay, also hold more liberal role attitudes toward their working wives. Thus, until recently, most of the decline in White women's domestic labor could be attributed to women simply doing less, or paying others to do the work for them, including housecleaning or purchasing services outside the home.

Recent evidence from U.S. time diaries shows some shift by husbands, and the ratio of women's to men's time in all unpaid work (housework, childcare, and shopping) has declined substantially

since 1965. This is both because of a decrease in women's housework and an increase in men's housework and childcare. Still, on average women do 1.6 times as much unpaid work as men. This situation is even less equitable when multitasking (doing two or more paid or unpaid work tasks simultaneously, such as doing laundry and preparing dinner, or doing laundry and clerical work) and all work time is considered. Because mothers do more paid work than in 1975 *in addition to* their unpaid work, and mothers do more multitasking, the ratio of mother's time to father's time spent in all work has *increased* since 1975.

Further, although in 1975 women and men had comparable amounts of free time, women now have less free time than men because women's time allocations to paid work increased more than their allocations to housework declined. Thus, access to free time is an emerging dimension of gender-related time use, and housework may be less important today in the symbolic production of gender.

The power relations underlying gender roles are perhaps most obvious in gay and lesbian families. Such families tend to be more egalitarian than heterosexual couples; partners have been raised with the same gender expectations, so the gender-related labor that is taken for granted in heterosexual households must be negotiated. In this regard, research finds that the perception of equity in housework is more egalitarian among lesbian couples than heterosexual couples. Same-sex couples, who have both grown up in a world of gender roles that devalue women's work in the home, tend to rate their relationship as inequitable if either has to perform more "women's work."

Friendships

Friendships provide emotional intimacy and are important to both men and women. Men's friendships tend to focus on shared activities whereas women are more likely to emphasize talking and emotional sharing. Further, women are more likely than men are to seek social support from friends when they have problems. And although men report more same-sex friends than women do, men are more likely to be intimate with women than with other men. Men report that

friendships with women are more satisfying than friendships with men.

The biggest gender differences in friendship appear in relation to self-disclosure. Even though both men and women report that they value intimacy, research finds that women share more about themselves and their feelings with same-sex friends than do men. Although some researchers point to socialization as an explanation for the observed differences, gender inequality, such as differential access to various social resources, plays an additional role. For instance, in the United States, the 19th-century transition to the market-based industrial economy changed the ways that men and women related to social institutions and to one another. Men's interactions in the public sphere allowed them little privacy and hence restricted their ability to engage in self-disclosure. In contrast, White, middle-class women, excluded from paid work and suffrage and confined to the domestic sphere, adopted new home-based responsibilities, including emotional responsibility for children and husbands and hence, self-disclosing intimacy with similar women nearby, such as neighbors, as well as with family.

This brief overview of gender roles in relationships points to the ways in which the expected behaviors of men and women are tied to gender relations and the power differentials therein. Women's gender roles tend to be tied to work for others, which gives them stronger support networks over the life course, whereas men's lend them greater autonomy and status.

GENDER STEREOTYPES

Gender-associated beliefs influence how people respond to us from the cradle to the grave. From birth, our parents shape our world based, in part, on their beliefs about what boys and girls are and should be like. As we develop, we learn how to interact with members of the same and the other sex, both in groups and as individuals. Friendships, family relationships, romantic partnerships, and workplace associations are affected by cultural beliefs about the sexes. This entry focuses on gender stereotypes, defined as organized, consensual beliefs and opinions about the characteristics of women and men and about the purported qualities of masculinity and femininity. As will be discussed, people hold gender-associated beliefs about the basic categories of “woman” and “man,” but usually recognize that men and women are also simultaneously members of other social groups, and they hold more fine-grained stereotypes about these subtypes. The extent to which gender stereotypes influence relationships depends on the social context of the relationship and on the power and status associated with the male and female gender role.

Gender-Associated Beliefs

Until recently, most research on gender stereotypes focused on the basic category level. Early work from the late 1960s and early 1970s identified two constellations of traits, one associated with women and one associated with men. Stereotypes about women are represented by a *communal* or *expressive* cluster that includes traits such as emotional,

kind, and understanding. Stereotypes about men are represented by an *agentic* or *instrumental* cluster that includes traits such as active, competitive, and self-confident. These characteristics are the core of two well-known measures of gender stereotyping, the Bem Sex Role Inventory and the Personal Attributes Questionnaire. These measures are used to assess people's perceptions about their own traits and their beliefs about others' traits. In an average sense, women's and men's self-assessments correspond to the gender stereotypes they apply to others.

More recent work has demonstrated that gender-associated beliefs are multidimensional; to capture the full picture of gender-based stereotypes, one must consider the roles women and men occupy, their physical characteristics, their cognitive abilities, and their emotions. Women's roles, for example, are stereotypically assumed to include cooking the meals and caregiving, whereas men's roles are assumed to include being the breadwinner and being a leader. Men are stereotypically described as tall and rugged whereas women are described as pretty and petite. Women's cognitive skills are believed to include an artistic bent and strong verbal skills; beliefs about men's cognitive abilities center around their strong mathematical skills and their ability to reason. Finally, people hold stereotypic expectations about appropriate emotions for the sexes. In general, women are seen as both experiencing and expressing more emotion than men do; emotions associated with women include happiness, embarrassment, love, fear, and distress. Only two emotions, anger and pride, are stereotypically associated with men.

Characteristics of Gender Stereotypes

Gender stereotypes have several characteristics that merit attention. First, as with most stereotypes, there is both a descriptive component, representing the content of people's beliefs, and a prescriptive component, representing what people believe others *should* be like. In the context of a heterosexual partnership, for example, beliefs about gender roles often lead to the assumption that women ought to have greater responsibility for the children and that men should naturally assume the role of breadwinner. A second characteristic of gender stereotypes is that they are

remarkably stable. Respondents in the United States have beliefs about gender that are similar to those held by Germans or Koreans; John Williams and Deborah Best, for example, found that respondents in 30 countries held similar gender stereotypes. Respondents in the new millennium hold beliefs similar to respondents in 1970, and older adults hold views similar to younger people. There is an exception to the general finding that gender stereotypes are stable, however; Amanda Diekmann and Alice Eagly found that today's women are viewed as more agentic than women in the 1950s and that people expect that women and men will become more similar in agency in the future. Men's agency, however, is not viewed as changing over time, nor is either women's or men's communion. Such perceptions are consistent with the power and status women are gaining in a variety of roles.

One question that often arises is whether gender stereotypes are accurate and, at the group level, they appear to be. Judith Hall and Jason Carter, for example, studied 77 traits and behaviors and found that people's stereotypic beliefs correspond to women's and men's self-reported characteristics. This correspondence, however, does not tell us what individual women and men are like. Although men are generally more aggressive than women, for example, there are certainly aggressive women. At best, stereotypes provide global cues about group members' characteristics; that people can readily identify gender stereotypes does not mean that they should endorse them.

Gender Polarization

Another important characteristic of gender stereotypes is reflected in people's assumption that gender-associated characteristics are bipolar. That is, people believe that what is masculine is not feminine and vice versa. This perceived gender polarization leads people to view gender-associated characteristics as a package: a person with feminine traits, for example, is believed to occupy feminine roles and to have feminine physical characteristics. Similarly, a person who occupies a masculine role is believed to also have masculine traits and a masculine appearance. People also make predictions about a person's sexual orientation, based on their perceived gender-associated characteristics. Men with feminine characteristics,

then, are often assumed to be gay and, to a lesser extent, women with masculine characteristics are often assumed to be lesbian. Finally, gender stereotypes are strongly associated with judgments of power and status; the more powerful, higher status roles are associated with men and masculinity and the less powerful, lower status roles are associated with women and femininity. Yet men's greater perceived power does not mean men are preferred; instead, research suggests women are liked better than men, a finding Alice Eagly and Antonio Mladinic have dubbed the *women are wonderful effect*.

Subtypes of Women and Men

The research discussed so far addresses beliefs about the basic social categories of woman and man. However, research has identified more than 200 gender-associated subtypes. These subtypes capture the reality that women and men also are of a particular age and ethnicity and that they occupy many different social roles. These subtypes can be grouped into major categories including occupations (manager, secretary), family roles (housewife, family man), ideologies (punk, libber), physical features (jock, athletic woman), and sexuality (macho man, sexy woman). When classifying others into subtypes, people appear to first create separate subtypes for women and men. However, people also use a traditional (e.g., housewife) or modern (eternal bachelor) dimension in their groupings and make distinctions between younger (adolescent, prissy girl) and older (granddad, old maid) gender-based subtypes.

Susan Fiske and her colleagues have shown that stereotypes can be classified along two global dimensions: a warmth dimension, related to the communal stereotype associated with women, and a competence dimension, related to the agentic stereotype associated with men. These dimensions are applied independently when judging subtypes of women and men. People may view managers as competent, for example, but also see them as cold. Similarly, people may see housewives as warm but may not respect them. Echoing the research on basic social categories, subtypes that are viewed as competent are seen as having higher status than are subtypes that are viewed as warm.

Influence of Context

People need to process stereotypic information quickly to make sense of their social world; otherwise, they would be overwhelmed by the amount of information they face. Because of this, at first pass, people often automatically rely on gender stereotypes. Mahzarin Banaji and her colleagues, for example, have shown that when people are primed for (or subconsciously made aware of) gender stereotypic traits, they subsequently judge others in gender stereotypic terms and are faster at making gender-related judgments such as identifying which names are associated with women or men.

Despite the ubiquity of gender-based stereotyping, however, in actual interactions, perceivers may eschew these stereotypes, turning instead to a more fine-grained assessment of women and men. Kay Deaux and Brenda Major have proposed a comprehensive model of how, when, and why gender influences behavior. In their model, the context sets the stage for the interaction; if this context is highly gendered, such as a romantic setting, people are more likely to rely on gender stereotypes. In contrast, during a business meeting, people are likely to rely on workplace-related cues and, accordingly, may be less likely to use gender-associated beliefs as a guide. This model also assumes that perceivers and their interaction partners are not passive players; that is, both parties in an interaction work in tandem and how their interaction progresses determines the extent to which gender stereotypes influence that interaction.

Even so, gender-associated beliefs can create a double bind for people who step outside gender roles. Women who fulfill a traditional male leadership role, for example, can experience prejudice as a result of stereotypic expectations. Madeline Heilman has proposed the stereotype-fit hypothesis to explain why women are less likely to occupy the manager role than are men. Her model postulates that the characteristics associated with effective manager are similar to the characteristics associated with men (and quite different from the characteristics associated with women). Hence, people see congruence between "man" and "manager" and a disconnect between "woman" and "manager." The perceived fit for men and the perceived lack of fit for women results in more men being selected as managers. And, even when

women are chosen to be managers, the belief that their characteristics do not fit the role can result in more negative performance evaluations and, ultimately, can affect their opportunities for further advancement.

Although the stereotype-fit hypothesis addresses gender stereotyping in the workplace, research suggests that these processes apply in a variety of settings; men, for example, who assume primary care for their children often experience negative reactions from family and friends, presumably because of the perceived lack of fit between male and caregiver. More generally, passive men and aggressive women are viewed less favorably than are men and women who behave consistently with their gender roles. However, individuals who endorse a blend of gender-associated characteristics are liked more than are those who are one-dimensional, even if that one dimension is completely gender congruent.

A limitation of the research described here is that researchers, either implicitly or explicitly, assess stereotypes associated with White women and men from the middle class. The relatively few studies that have examined stereotypes of other groups show that this presents an incomplete picture. Gender-related beliefs about Black men and White men are similar, for example, but Black women and lower-class women are seen as less feminine than are White and middle-class women. Similarly, research suggests that stereotypes of other social categories, such as age and sexual orientation, are linked to gender stereotypic beliefs. Another limitation is that the people who are reporting their stereotypic beliefs are themselves usually White and middle class; the views of other social groups are largely unrepresented. Research addressing this shortcoming is long overdue.

GOAL PURSUIT, RELATIONSHIP INFLUENCES

Goal pursuit (also called goals, motivation, self-regulation) is a common part of the everyday experience. People place great importance on their personal aims, whether they be career goals (e.g., finish a project by noon, impress a new client), health goals (make it to the gym every day), or financial goals (save money for retirement), to name a few common types of goals. Although people don't tend to think about how their personal goals might affect their relationships with friends, family members, romantic partners, and colleagues, research suggests that the impact of personal goals on interpersonal relationships can be strong. Similarly, although people aren't necessarily aware of it, interpersonal relationships with friends and family can affect the kinds of personal goals pursued and how they are pursued.

Imagine that Annie has a goal of becoming a successful lawyer. She knows that this goal will determine much about her professional and academic life—her path through school, where she considers moving, her financial plans, and her study hours will all be affected by her goal to

become a lawyer. Less obviously, this goal will determine much about Annie's social life as well—her friendships, family relationships, and romantic relationships will also be affected.

Now imagine that Annie starts a new romantic relationship. She knows that her new partner will determine much about her romantic and social life—the way she spends her weekends, her social activities, and her sex life. Less obviously, this new relationship will determine much about her professional and academic life as well—her academic goals, career goals, and financial goals will also be affected.

This entry discusses how people's personal goals shape their thoughts, feelings, and behavior in their most intimate relationships and how people's intimate relationships can shape their personal goal pursuits.

Interdependence of Goals and Relationship Partners

Relationship partners have many opportunities to facilitate or obstruct each other's goal pursuits within everyday interactions: For example, a husband can make breakfast for his wife, saving her time in the morning and giving her energy for a day at work, or he can forget to take out the garbage, costing her time and increasing her stress level before a day at work. As a more serious example, a husband can stay home with a new baby so that his wife can pursue her career, or he can accept a new job in a new city, disrupting his wife's career. Dozens of times throughout the day, in both tiny and consequential ways, people have opportunities to either help their partners pursue goals or (whether intentionally or accidentally) to stand in the way of goal pursuit.

Interdependence Theory describes goal pursuit as woven into the very fabric of social relationships. Indeed, few people could achieve their goals without facilitation by family, friends, colleagues, and romantic partners—if they were obstructionary, intentionally or unintentionally, goal pursuit would be exceedingly challenging. This is one way that researchers have thought about the interplay between goals and relationship partners—by suggesting that relationship partners can influence one's ability to achieve goals, and shape which

goals people choose to pursue. For example, people are likelier to pursue goals they feel their romantic partner will support and facilitate; they are also likelier to pursue goals that are compatible with their partner's goals. If Annie's husband hates exercise and enjoys spending his evenings relaxing with Annie, she is less likely to pursue a goal of training for a triathlon, knowing her husband wouldn't be supportive and that she would be interfering with his own goal to relax together at night. Ellen Berscheid's Emotions in Relationships Model emphasizes how the interplay of goals and relationships has important consequences for goal pursuit and for relationships: Feelings about relationship partners are thought to be determined by how those partners obstruct or facilitate one's goals, such that people feel closer to partners who help their goals, and less close to partners who hinder them. Both theories predict that when romantic partners' goals are compatible—Annie hopes to lose weight and Aidan wants to start cooking more healthfully—the couple will be more successful in their goals and feel more positive emotion toward each other. When romantic partners' goals conflict—Annie hopes to lose weight and Aidan wants to become an expert baker—the couple will be less successful at their goals and feel more negatively about each other.

Effects of Relationship Partners on Goals

How do friends, family members, and romantic partners influence people's ability to successfully pursue their goals? One answer comes from the literature on *social support*. Although there are many definitions of social support, most of the psychological research on the topic focuses on the benefits of helping relationship partners cope with stressful life events and challenges. For example, researchers have studied how relationship partners support individuals as they struggle through trying circumstances, such as preparing for the bar exam. A large body of research has established that social support of this type—helping partners cope with stress—leads to more satisfying relationships, as well as greater emotional and physical health and well-being. Of course, by providing support (or failing to provide support) in times of strife and challenge, relationship partners also

affect individuals' ability to successfully manage these challenges and succeed at their goals.

Social support can also consist, however, of more directly helping partners enhance their personal development and successfully pursue their goals. Brooke Feeney has shown that having a supportive partner frees people to pursue their goals more confidently, much as having a reliable parent nearby can free children to explore a playground more confidently. Thus, by openly offering support to each other, relationship partners can paradoxically increase each other's independence; this is one more route via which relationship partners can shape the self's goals.

Relationship partners can also have a more subtle impact on the goals that people pursue. Recent research has shown that individuals create—and over time, ultimately automate—mental links between relationship partners and the goals that individuals commonly pursue in the presence of these partners. In a long-term relationship, such as with a romantic partner or close friend, individuals slowly develop strong mental associations between their goals and these important relationship partners, links that can have important consequences for goal pursuit. That is, just being around a particular partner may automatically trigger the “linked” goals, which then may shape behavior.

Indeed, studies have shown that for students who have a goal to make their parents proud by achieving at university, subtle reminders of their parents can lead them to work harder and be more successful. These results suggest, for example, that if Annie often spends time with a certain friend when training for a triathlon, just being around that friend may trigger Annie's health and fitness goals. However, these findings have an important qualification: People don't always act in line with these triggered goals. Subtle reminders of overly controlling or manipulative relationship partners can actually produce the opposite effect. For example, when students are reminded of a controlling partner who wants them to work hard, they react by working *less* hard—to defy the controlling other's wishes. Thus, although in most situations people go along with their partner's goals for them, they are unlikely to do so when they feel their freedom is being threatened, as with a domineering partner.

Interpersonal goal conflicts are another route through which relationship partners can influence

each other's goals. For example, when people's personal goals (e.g., to eat healthfully to lose weight) conflict with their social or relational goals (e.g., to have fun with their friends at a barbecue), recent research has shown that relationship partners can lead people to temporarily abandon their personal goals. Of course, people will not always abandon their personal goals in favor of their social goals; indeed, recent research suggests that striking a balance between the pursuit of personal and social goals is important for life satisfaction and well-being.

Effects of Goals on Relationship Partners

Thus, research has suggested that relationship partners can influence goal pursuit. But what about the reverse? How do goals influence relationships? For example, if a romantic partner helps or hinders someone's ability to achieve a desired goal, how does this influence that person's feelings about the romantic partner?

Recent research has addressed this question by looking at how friends' and romantic partners' *instrumentality* (i.e., usefulness) for students' achievement goals affects how the students feel about their relationships. For example, in one study, students nominated relationship partners who were instrumental or non-instrumental for their academic achievement goals, and were subsequently reminded of their achievement goals by a technique known as “goal activation,” in which goal-related words are presented in a subtle fashion to activate the mental representation of the goal. Next, students evaluated their feelings of closeness to the relationship partner, as well as rated the importance of the relationship compared with other relationships.

When an academic achievement goal was activated, students felt closer to instrumental relationship partners, wanted to spend more time with them, and had greater motivation to approach those others. They also felt less closeness to relationship partners who weren't instrumental for active goals, wanted to spend less time with them, and had greater motivation to avoid those others. This research suggests, for example, that if Annie wants to lose weight, she would feel closer to her husband Aidan if he learned to cook healthfully

and feel less close to Aidan if he learned to become an expert baker of cakes and cookies.

Importantly, then, being instrumental for the achievement of a partner's goals can be beneficial for the relationship, and failing to be instrumental can have relational costs. Just as research has shown that being supportive for a partner's goals helps the partner achieve goals and be more independent, this research shows that being supportive for a partner's goals can reap benefits for the relationship.

Interplay of Personal and Relationship Goals

Of course, people don't just have personal goals—goals to lose weight, save money for a new car, or earn a new promotion. People also have important interpersonal goals—goals to make new friends, get along better with in-laws, or become closer to a new romantic partner. These kinds of relationship goals may surpass personal goals in their importance and influence; most people name their close relationships as their most important value in life. In many cases, personal goals (achievement, health, career goals) may ultimately serve more fundamental relationship goals (finding a romantic partner, building a happy family, belonging to a social group). If so, it would be counterproductive to promote personal goals at the expense of relationship goals: It certainly would not be wise to derogate your partner for not helping you lose weight if your reason for losing weight is to stay attractive for your partner.

GOALS IN RELATIONSHIPS

Goals may be defined as the events, outcomes, and feeling states that we desire. Most of the things we want in life occur in the context of our relationships with other people. If you can imagine what your life would be like alone on a desert island (like Robinson Crusoe), you can appreciate how achieving most of your goals would be impossible without other people. This entry will first consider some core social goals or motives that characterize all of our social interactions. Next, the special goals people seek in close, romantic relationships will be considered. The last sections will examine some of the factors that determine the relative importance of different goals, with a special focus on the different goals men and women may have for close relationships.

General Social Interaction Goals

Starting with William James, psychologists have long believed that goal seeking is a fundamental aspect of human behavior. One early social

psychologist named William McDougall proposed a list of instincts—such as fleeing because of fear and seeking because of curiosity—that guided all behavior. More recently, Susan Fiske drew attention to the interconnected goals of belonging, understanding, controlling, enhancing self, and trusting others in her BUCET (or bucket) framework. The goal of *belonging* leads people to seek out others to bond as dyads or become part of a groups. Our moods typically benefit from these associations, and our health, adjustment, and well-being may suffer if we are deprived of these social connections. The goal of *understanding* is instrumental to achieving a sense of belonging because we need to perceive others accurately to predict their actions and coordinate with them. In addition, a sense of understanding and certainty allows people to feel in control and is beneficial to health. Other people can promote our sense of certainty by agreeing with our opinions, providing us with social validation. The goal of *controlling* is evident when people strive for competence in their social interactions, often with the goal of assuming leadership or directing the behavior of others. When people feel that their sense of control is threatened, the need appears to grow stronger. For example, people with an ambivalent attachment style often feel suspicious of their partners, clinging to them in a jealous and controlling manner.

The goal of *enhancing the self* manifests itself in our efforts to keep our self-esteem at a high level and in our constant quest for self-improvement. Our interactions with other people are, of course, crucial to accomplishing this goal. For example, people seek out others who will provide social support by validating their opinions and complimenting them on their accomplishments. Just knowing that one is in a committed romantic relationship, in itself, can be a source of self-esteem for many people. One explanation for this increase in self-esteem is that the self “expands” when we form a close relationship, and this expansion increases our satisfaction with the relationship. Finally, the goal of *trusting others*, particularly those in our ingroup, allows us to maintain a sense of optimism and interact with others in a confident manner. When bad events do occur (such as interpersonal betrayal), they are typically unexpected and prompt a quick response to deal with them. People feel a sense of loyalty to their group that promotes cooperation

and prepares the group to compete more effectively with outgroups.

Although these five goals are believed to be a universal part of human nature, the strength of the goals may vary across different cultures. For instance, the goal of understanding seems to require greater social unanimity and harmony in a collectivist culture compared with an individualist or independent culture. Individualist cultures seem to be more accepting of diverse opinions and behavioral styles. As another example, compared with collectivist cultures, individualist cultures seem to promote a more trusting and optimistic view of others, particularly those in the outgroup.

Specific Goals Sought in Romantic Relationships

The five goals reviewed in the previous section are also relevant when people choose their romantic partners. For example, being married is likely to satisfy one’s need for belonging and provides opportunities for receiving social support and understanding from a partner. The marital link also carries with it a high degree of dependence and potential control over one’s family, especially when children are part of the relationship.

Marital partners are vulnerable to one another such that trust is central to the success of the relationship. The close, trusting bond of marriage can also enhance the self-esteem of the partners.

But when people consider entering into a romantic relationship, some unique goals come into play. The goal of finding sexual passion and excitement represents one such unique focus. Goals related to seeking social or economic status and preserving one’s independence may also become important as the relationship matures. Moreover, goals related to belonging and trust may take a different form in a romantic relationship. For example, people may desire a deeper level of commitment and intimacy from a romantic partner than from a casual friend or coworker.

Garth Fletcher and Jeff Simpson suggest that people have ideal standards (or goals) in mind when they evaluate intimate relationship partners and when they think about the relationship itself. These standards operate as knowledge structures or schema that allow us to evaluate the suitability

of prospective partners. For example, if our goal is to find a sexy, exciting lover, we may turn down the advances of someone who is rich, charming, but homely looking. Once the relationship is in progress, these goals also regulate the progress or changes that may take place. For instance, if one of the partners is primarily interested in social status, that partner may consider exiting the relationship if couple is facing bankruptcy or home foreclosure. In general, people will be more satisfied with their partner and the relationship to the extent they feel their goals and ideals are being met.

Much of the work in this area is guided by theorizing about how evolutionary pressures guide mate selection. The underlying assumption is that individuals seek mates who will promote their own reproductive fitness. A prospective partner can signal his or her mate value in a variety of ways. Qualities associated with (a) being a good parent; (b) appearing young, healthy, and fertile; and (c) having the potential to achieve high social status may be particularly important. With this evolutionary focus in mind, researchers in the area of close relationships have focused most on the following goals. First, people seek *intimacy, trust, and commitment* from their romantic partners. These qualities signal that a partner is likely to be a good investment in terms of providing emotional support, cooperation, and care giving, especially for children. Second, people tend to seek *passion and excitement*. A partner who is young, attractive, healthy, and energetic will score high along this dimension. Cues of this sort signal high reproductive potential (fertility). Third, people seek *social and economic status*. By mating with a partner who is ambitious or appears able to climb social hierarchies, one increases the chances of having sufficient material resources to live comfortably and raise a family. Fourth, people may value their *freedom and independence*. Strong values of this sort may interfere with the formation of a mating bond. For instance, some people shy away from marriage for fear of being “tied down.” But even in successful relationships, partners often need to negotiate how time and money are spent to preserve a sense of individuality.

Finally, people may rely on the relationship to *raise self-esteem*. Close relationships can bolster self-esteem in a variety of ways. Simply being married, for example, may carry some prestige, perhaps

indicating that one is valued and accepted. In addition, by linking ourselves with a partner who possesses socially desirable qualities (e.g., beauty, intelligence, or social status), we indirectly signal our own value. After all, if we can attract such a desirable mate, we ourselves must possess many good qualities. Psychological processes related to self-expansion and social support also come into play. Accordingly, the bond with our partner broadens our world and offers opportunities for our partner to support us in good times and bad. Partners often idealize each other, seeing both their partner and the relationship through rose-colored glasses. This tendency may further increase self-esteem and is associated with greater relationship satisfaction. Given these considerations, the dissolution of a close relationship can be devastating to our self-esteem.

Factors That Influence the Importance of Different Relationship Goals

The relative importance of the five specific relationship goals just presented is not rigid and is influenced by both situational factors and individual differences among people. The following section considers how goal importance is influenced by male versus female differences, length of the relationship, cultural factors, and individual differences in attachment style and sociosexual orientation.

Male Versus Female Differences

When discussing our ancestral past, evolutionary models suggest that men and women faced different challenges in mate selection. Men were faced with the challenge of finding women who signaled their reproductive potential with youth and good looks. Men who had sex with many such women tended to succeed in the reproduction game by leaving many children behind. In contrast, the challenge for women was to find men who could provide material resources (e.g., food and shelter) to the family unit. As products of their ancestral pasts, therefore, modern males put greater stress on a partner's physical attractiveness, whereas modern females put greater stress on a partner's earning potential or social status. Indeed, many studies—including those that analyze personal want ads—suggest that men often seek beauty in their partners,

but women often seek financial stability. Although these differences are certainly consistent with evolutionary theorizing, sociocultural explanations may be equally plausible. For example, the different preferences of men and women are likely to be shaped by traditional sex role socialization and the fact that, in many cultures, women suffer from restricted economic opportunities.

Short-Term Versus Long-Term Relationships

The different mating preferences of men and women described earlier are most evident in choices concerning a short-term mating partner, compared with a long-term partner. That is, when short-term relationships are considered, men are much more likely than women to seek a large number of partners who are young and attractive. Still, the sexes are alike in some ways. When it comes to choosing a partner for a long-term relationship, most people emphasize the warmth and trustworthiness of the partner. But when choosing a partner for a short affair, most people will emphasize the physical attractiveness of the partner. In addition, both men and women people are more selective about a long-term partner than a short-term one. When considering marriage, for instance, prospective partners are likely to place strong emphasis on all of the goals discussed.

Cultural Factors

In many individualist cultures, such as the United States, people tend to believe in romantic love, including the notion that one is entitled to a partner who is physically attractive. In some collectivistic countries such as India, however, the idea of romantic love is less prevalent. Instead, parents often arrange the marriages of their children with practical goals such as achieving long-term stability in the marriage and forging family alliances. Consequently, the goals of finding a partner high on intimacy/trust and social status tend to rank higher under these circumstances.

Individual Differences in Attachment Style and Sociosexual Orientation

Individuals who vary in their attachment styles may stress different relationship goals. For

example, someone with an anxious style of attachment might be especially concerned with intimacy/trust and self-esteem issues, but little concerned with freedom and independence issues. In contrast, someone with an avoidant attachment style might put less emphasis on intimacy/trust and self-esteem, but be highly concerned about maintaining some degree of independence outside of the relationship.

Finally, individuals vary in their sociosexual orientation. Some people have a more “restricted” sociosexual orientation in the sense that they would have sex with someone only if they felt a close, committed, emotional bond to the person. In contrast, those with an “unrestricted” orientation are willing to engage in sex without such preconditions. Not surprisingly, research indicates that people with an unrestricted sociosexual orientation put less emphasis on intimacy/trust when choosing a partner.

GOD, RELATIONSHIPS WITH

People may perceive themselves as being in relationships with other people, as well as with God or some Higher Power. (In this entry, “God” is used for brevity.) Many people experience connections to God that include relational elements: communication, attachment bonds, and the potential for conflict. However, this particular relationship differs in important ways from interpersonal relationships. First, although many people report that they can sense God’s presence, most people do not report seeing or hearing God in a direct, physical way. Second, God is typically seen as being much more powerful than humans. For example, the monotheistic (“one God”) traditions of Judaism, Islam, and Christianity usually portray God as all-knowing, all-powerful, and capable of being everywhere at once. Third, many people see God as morally perfect and incapable of sin. Given these important differences, relationships with God cannot be reduced to simple interpersonal relationships, even though they share many features.

The idea of a relationship with God fits most easily within certain faith traditions: those focusing on a personal God who intervenes in people’s lives. Such beliefs are more likely in Protestantism than in Zen Buddhism, for example. Existing research has overemphasized Western, Christian samples, yielding a somewhat lopsided picture of how humans experience the sacred. Yet the concept of a relationship with God may apply to some who do not regard God as a personal, relational being. For instance, studies suggest that people can become angry at impersonal forces such as tornadoes or illnesses. People can also experience a profound sense of communion with nature, which is usually seen as an impersonal force. Thus, some relational concepts presented here may apply to

faiths that do not include a personal God. For simplicity, this entry emphasizes religions that include one God. The dynamics become more complex in religions that include more than one God.

Communication

One crucial ingredient of relationships is communication, and most religions do frame prayer as communication with God. Prayer, like conversation, takes many forms: petitions, complaints, expressions of gratitude, and simple sharing of thoughts or happenings. At one level, prayer could be seen as an internal dialogue or a one-way form of communication, and some people do see it this way. Some see prayer as two-way conversation, believing that God speaks to them through forms such as sacred texts, impressions or images, or external events.

Yet prayer is not the same as ordinary conversation. Prayer involves a “virtual” element, because people typically do not claim to see or hear God directly. (Given the myriad communication problems that characterize human relationships, one can only imagine the difficulties that can ensue when one’s partner is not visible or audible!) Also, because God is often seen as holy and all-powerful, prayer sometimes takes the form of worship or confession of sins; this clearly takes it out of the realm of everyday interpersonal conversation.

Attachment Bonds

People often hold internalized images of God that reflect both their male and female caregivers from early in life. Studies also suggest that many people respond to God as an attachment figure: They want to stay close, seeing God as a secure base and a haven of safety, and they experience anxiety when there is a threat of separation.

One controversy in the attachment-to-God literature centers on how perceived relationships with God differ based on attachment style. Some evidence supports a correspondence hypothesis, in which people’s relationships with God mirror their relationships with parents or romantic partners. For example, people who see their parents as harsh, distant, or cold often tend to have similarly negative images of God. Other evidence supports a

compensation hypothesis, in which people compensate for insecure attachments in other relationships by seeking greater closeness to God.

As noted by faith development researchers, attachment bonds do not need to remain in a passive, infantile form. Some people experience connection with God as a leader-follower relationship, a mutual partnership, or a romantic love relationship. They may see themselves as partners or as a part of God's team. However, because people often see God as being holy and all-powerful, even a close partnership is usually not seen as an equal-status relationship.

Relationship Conflict

As with human relationships, negative events can prompt negative feelings and conflict in people's relationships with God. When people believe that they have transgressed against God, they often feel guilt, shame, and a desire to seek forgiveness. In other cases, God is seen as the one who has caused harm. When facing death, accidents, natural disasters, or even everyday disappointments, people who attribute such events to God can become hurt and angry. They may feel abandoned or betrayed, and some will assume that God is punishing or rejecting them. In many ways, the resulting emotions are similar to those surrounding interpersonal conflicts.

Here again, though, there are some key differences from interpersonal relationships. Because people usually view God as extremely powerful, many fear retribution (e.g., the lightning bolt from heaven) if they acknowledge anger or negative feelings toward God. As a result, people may hide negative feelings from others and perhaps even from themselves. The topic of anger toward God is often considered taboo.

Because people typically do not see or hear God with their senses, they often use cognitive means to resolve conflicts regarding God. For example, some people revise their God images, envisioning God as less powerful, benevolent, or protective than previously believed. Others conclude that God does not exist or that God's ways are ultimately unknowable.

Another difference from human relationships is that many people see God as incapable of error or wrongdoing. Thus, when negative events occur,

many people seek explanations that do not imply transgression on God's part. Some shift responsibility elsewhere, pointing the finger at themselves, another person, or the devil. Others reframe God's actions in a positive light, finding benefit in them or trusting that they are part of greater plans that are meaningful but mysterious.

GOSSIP

Gossip is ubiquitous. Anthropological literature suggests it is virtually universal in human societies, and ethnographic data often reveal a high percentage of gossip in common conversation. Most people encounter gossip in one form or another in the course of a day, either in conversation or from the media. It can be entertaining or dull, useful or destructive. Some researchers have argued persuasively that gossip provided evolutionary advantage to the human species. Modern societies have institutionalized the activity in mass media. This entry focuses on the social functions of gossip, in the context of interpersonal exchanges and at the level of larger social groups.

Gossip may be defined as the exchange, in a context of congeniality, of personal information (positive or negative) in an evaluative way (positive or negative) about absent third parties. Interpersonal gossip is typically traded among (and about) people who have a common history or shared interests. Thus, the evaluative elements in

gossip arise from implicit comparisons to social norms to which the conversationalists tacitly subscribe. That is, if people share a social history, remarks exchanged about others in their circle will frequently express or imply comparisons to norms based on known elements of that history.

In defining gossip, the context, setting, and tone of a conversational exchange must be considered. Congenial informality is perhaps the key situational factor that differentiates gossip from other kinds of evaluative exchanges about someone not present. That is, a mood of familiarity, novelty, and a certain “thrill” are essential to the expression of gossip. Parents discussing their child’s performance in school with a teacher, for instance, although conforming to the letter of the definition given, would therefore not be considered gossip because the spirit of the conversation lacks the kind of spontaneity and excitement we usually associate with this form of communication.

Although researchers often include positive gossip in the domain, the behavior commonly elicits disapproval and opprobrium colloquially, primarily because the popular assumption is that it disseminates only negative content whose truth value is frequently in question. How much effort gossipers or gossipees take to validate the content of gossip may depend on the individual and the milieu (e.g., workplaces, Internet chat rooms, neighborhoods, dormitories, etc.). In gossipy conversation, phrases such as, “I’ve heard that . . .,” “It seems to me that . . .,” “An inside source said . . .,” “I saw him doing . . .,” “. . . or so I’m told,” and so on each convey a slightly different truth value on the accompanying information. Verification of gossip by the gossipee is typically cursory. People seem more likely to rely on casual and indirect confirmatory indicators, such as the status or expertise of the source, than to seek direct access to information when evaluating the truth of gossip.

Researchers have delineated numerous social functions of gossip. It is frequently described, for example, as an efficient and, occasionally, even exclusive means of gathering and disseminating social information. Along these lines, and as developed in social exchange theory, gossip can be seen as a kind of currency, traded like any other, and assessed for its value by the taker on the basis of timeliness, usefulness, and, especially, rarity. This accounts for how an individual may boost his or

her social status—temporarily, at least—by being the first to pass a piece of gossip.

Another important function of gossip is to help form and solidify friendships or intimacy. Between friends, sharing gossip is a way to telegraph confidence in the “dyadic boundary” and thereby cement the relationship and distinguish insider from outsider. Indeed, newcomers may find themselves struggling to stay up to speed in casual conversations among longtime friends, as meanings are firmly rooted in long and complicated histories of experience and information exchange. At the group level, what begins as trusted exchanges in private becomes the knowledge, norm, and trust margins of communities, cultures, and other bounded social identities. This phenomenon may be a means by which long-simmering ethnic tensions remain salient over decades or even centuries: Whispered gossip between members of one group perpetuates the inclusion of like members and the exclusion of members of another group, and the process is repeated innumerable times in innumerable private exchanges.

Perhaps the most evident social function of gossip is its simple entertainment value. As a form of immediate amusement and stimulation, gossip is readily available to everyone of almost any age in almost any situation for virtually no cost. The storytelling aspect of gossip can satisfy emotions in a quasi-literary way and may provide relief from the monotony of workplaces or from social isolation in any setting. Nearly everyone enjoys sharing gossip in one form or another (notwithstanding protestations to the contrary).

Finally, gossip is a means of social influence. As such, it may involve a different type of motivation than is generally encountered in its informative, friendship, or entertainment functions; the contrast hinges on influence being essentially a deliberate and meditated effort. In the workplace, for instance, sharing gossip with a new hire is a kind of informal initiation ritual that perpetuates norms, validates the status quo, or aligns political factions. More generally, with gossip, social cheats are criticized and paragons are praised. Norms are thus upheld, and group cohesion and boundaries are maintained. Culture in general depends on the repetition of norms and mores both formally and informally to enforce conformity on members. Gossip serves this social function well.

Learning what our fellow humans believe to be either praiseworthy or blameworthy is a serious task in life. To remove gossip from the behavioral repertoire would result in our learning important life lessons less early and less clearly. Therefore, gossip should not be reduced to a benign pastime, on the one hand, or to an evil instrument of indirect social aggression, on the other. It can mislead but it can also inform. It can fracture and mend. It can banish and welcome into the fold. Along with its ubiquity, this Janus-like character of gossip is why it has attracted more systematic attention and study recently.

GRANDPARENT–GRANDCHILD RELATIONSHIP

As a result of increased life expectancy, most adults spend a considerable portion of their lives as grandparents. Increased life expectancy also means that most children have long-term relationships with multiple grandparents. As such, the grandparent–grandchild relationship is a significant family bond. Although there is great variation within individual grandparent–grandchild relationships, the relationship is highly valued and

beneficial. This entry examines the nature of the grandparent–grandchild relationship, variations in this relationship, factors that influence grandparent–grandchild involvement and closeness, and consequences of a positive grandparent–grandchild relationship.

Although grandparents can be abusive toward their grandchildren or absent from their lives, most grandparents and grandchildren have long-term, loving relationships marked by high levels of affection, contact, and emotional closeness. Grandparent–grandchild relationships have been described as mutually satisfying, particularly when they are reciprocal (both parties actively participate) and symmetrical (both parties share similar feelings).

Grandparents interact with their grandchildren in a variety of ways. They give gifts, serve as playmates, provide cognitive and social stimulation, offer advice, and supply emotional support. They also provide instrumental support in the form of money, free babysitting, or other tangible goods. Depending on the quality of the relationship between their children and grandchildren, some grandparents may serve as buffers within the parent–child relationship. Grandparents also link past and future generations and assume responsibility for transmitting family history, culture, traditions, and values. Additionally, grandparents indirectly influence their grandchildren by providing emotional and material assistance, serving as role models, stabilizing or assisting the family in times of crisis, and preserving extended family ties.

Although some adults find their relationships with their grandchildren to be uncomfortable or disappointing, most enjoy being grandparents. Grandparents appreciate the sense of biological renewal, symbolic immortality, emotional self-fulfillment, and vicarious accomplishment they receive from participating in their grandchildren's lives. Many grandparents also enjoy the opportunity to indulge their grandchildren without the added responsibilities of parenting and discipline. They may derive satisfaction from the opportunity to teach their grandchildren or provide them with financial or material resources. For grandparents who felt that their work responsibilities kept them away from their own children more than they would have liked, interacting with grandchildren may represent a “second chance” at parenting.

Just as not all grandparents enjoy their grandchildren, not all grandchildren feel close to or appreciate their grandparents. However, many grandchildren enjoy positive relationships with their grandparents. Although younger grandchildren thrive on the attention they receive from grandparents, adolescent and adult grandchildren often appreciate their grandparents' wisdom, support, and guidance. Older grandchildren may also view grandparents as confidants and approach them with problems that they do not feel comfortable discussing with their parents. Grandparents are so important to grandchildren that many adult grandchildren express a desire to support and care for their grandparents, especially when their grandparents need assistance with household responsibilities and personal care.

Variations in Grandparent–Grandchild Relationships

There is significant variation in how grandparents and grandchildren enact their relationships. Numerous researchers have identified distinct styles of grandparent–grandchild interaction. For example, in their seminal research, Bernice Neugarten and Karol Weinstein identified five ways that grandparents interact with their grandchildren:

1. *Formal* grandparents are involved in their grandchildren's lives and activities. However, they do not assume any parental authority or responsibility with their grandchildren.
2. Grandparents who are *fun seekers* enjoy an informal, pleasurable relationship with their grandchildren. They view time with their grandchildren as a leisure activity.
3. Grandparents who are *surrogate parents* assume caregiving responsibilities for their grandchildren.
4. *Reservoir of family wisdom* grandparents, who are typically grandfathers, behave as authority figures and sources of knowledge. They tend to have emotionally distant relationships with their grandchildren.
5. *Distant* grandparents have limited contact with their grandchildren. They may only see their grandchildren on holidays and birthdays.

Although there have been several other classifications of grandparent–grandchild relationships, this example illustrates the broad range of relationships that exist between grandparents and their grandchildren.

Factors Associated With Involvement and Closeness

The frequency of contact between grandparents and grandchildren, as well as the degree of emotional closeness within the relationship, has been associated with numerous individual and family factors. When considering frequency of contact, there is little association between the amount of contact and relationship quality. Thus, it is possible for grandparents and grandchildren to have limited contact, yet still report a highly satisfying relationship.

Individual Factors

Individual factors refer to personal characteristics of the grandparent or grandchild. Although the grandparent role is important and satisfying to both grandmothers and grandfathers, grandmothers tend to be more involved with grandchildren than grandfathers do. Grandmothers also tend to be more expressive in their relationships with their grandchildren—displaying a high degree of warmth and affection, especially to their granddaughters. In contrast, grandfathers tend to be more instrumental with their grandchildren, especially their grandsons, in that they provide assistance with education, employment, or finances. Grandchildren report the closest ties with their same-sex grandparents, with grandmothers and granddaughters reporting the closest relationships.

Lineage also affects grandparent–grandchild relationships. Because women are traditionally responsible for maintaining extended family relationships, maternal (the mother's side of the family) grandparents tend to be more involved with and closer to their grandchildren than do paternal (the father's side of the family) grandparents. Grandchildren also describe greater emotional closeness with their maternal grandparents, particularly their maternal grandmothers. Grandchildren are especially close to their maternal grandparents

when their mothers are single or the grandchildren have experienced parental divorce.

The age of the grandparent and the grandchild may affect their relationship. Younger grandparents, who tend to be in better physical health, are usually more active with their grandchildren. Although physical and cognitive declines may force older grandparents to be less involved with their grandchildren, grandparents' affection for their grandchildren usually does not diminish with age. Younger grandchildren tend to be more involved with their grandparents. Involvement begins to decline as grandchildren reach adolescence and continues as grandchildren launch their own careers and families. Despite these normative declines in involvement, grandchildren do not report age-associated declines in the quality of their relationships with their grandparents. Moreover, evidence indicates that involvement with grandparents increases again once grandchildren establish their careers and have children. Thus, involvement between grandparents and grandchildren may be cyclical and influenced by the grandparent and grandchild's stages in the life course.

Finally, the ethnic background of the grandparent and grandchild may influence their relationship. When compared with White grandparents, the grandparent role has been observed to be more important to Native American, African-American, Hispanic, and Asian grandparents. Additionally, minority grandparents are more likely than are their White counterparts to live with their grandchildren and assume significant childrearing responsibilities. Although there is wide variation in the exact nature of the grandparent–grandchild relationship among various ethnic groups, influential cultural factors include the degree of grandparental authority, the grandchild's sense of filial piety (responsibility to love, respect, and care for older family members), whether the grandparent lives with the grandchild, language compatibility, and degree of acculturation (how much a person or family has adopted the beliefs and behaviors of the dominant culture).

Family Factors

Characteristics of the family also influence grandparent–grandchild relationships. When grandchildren are young, their parents dictate the

amount and type of contact they have with grandparents. For this reason, the quality of the parent–grandparent relationship has a significant impact on the quality of the grandparent–grandchild relationship. More specifically, a positive relationship between parents and grandparents is associated with better grandparent–grandchild relationships. However, as grandchildren age, they can negotiate relationships with their grandparents that are independent of their parents. Generally, the quality of the relationship between adult grandchildren and their grandparents is similar to the quality of the relationship when the grandchildren were young.

Family structure can also affect interaction between grandparents and grandchildren. Divorce and remarriage can facilitate or disrupt grandparents' relationships with their grandchildren. For example, following a divorce, maternal grandmothers increase the amount of childcare they provide for their grandchildren. Maternal grandparents may also increase their financial support of their grandchildren. Alternately, as a result of divorce, paternal grandparents may lose contact with their grandchildren. Although some states allow grandparents who have lost contact with their grandchildren to seek visitation rights, some states do not allow grandparents to seek visitation. Remarriage also poses challenges for the grandparent–grandchild relationship. Grandparents often have a difficult time knowing how they should relate to their stepgrandchildren. Children tend to have better relationships with their stepgrandparents when they enter the family at a young age and live full-time with their stepgrandparents' adult child.

In response to changing family structures and other demands on families, many grandparents provide care for their grandchildren. The degree of responsibility grandparents have for their grandchildren ranges from occasional babysitting to full-time parenting. During the last 30 years, there has been a significant increase in the number of grandparents raising grandchildren. Hispanic, African-American, and Native American grandparents are especially likely to be raising their grandchildren. When grandparents assume responsibility for their grandchildren, they often experience numerous stressors including poverty, legal problems, health concerns, social isolation, and psychological distress.

Grandparent caregiving also affects the grandparent–grandchild relationship. The more a grandparent

provides care for a grandchild, the more likely the grandchild is to view the grandparent as a parental figure. Among grandparents who are not responsible for raising their grandchildren, the greater the degree of grandparent caregiving, the more frequent the contact and the closer the emotional relationship between the grandparent and grandchild. When grandparents raise their grandchildren, there may be increased emotional closeness. However, increased conflict and ambivalence is also common.

A final family characteristic that has been associated with grandparent–grandchild relationships is geographic distance. In an increasingly mobile society, many grandparents live a significant distance from their grandchildren. Greater geographic distance between grandparents and grandchildren has been linked to less frequent contact, less support, and lower levels of emotional closeness. However, the influence of geographic distance on the grandparent–grandchild relationship is complex in that it also intersects with the quality of the parent–grandparent relationship, the use of technology, the importance of grandparenting to the grandparents, and family members' previous experiences with grandparents.

Consequences of Grandparent–Grandchild Relationships

Research indicates that a positive grandparent–grandchild relationship is beneficial to the mental health and well-being of both grandparents and grandchildren. For example, Linda Drew and Merrill Silverstein found that grandparents experience increased symptoms of depression when they lose contact with their grandchildren. These depressive symptoms persist over time, which can be detrimental to grandparents' health, functioning, and personal relationships. Similarly, Sarah Ruiz and Merrill Silverstein found that when adolescent and young adult grandchildren are emotionally close to their grandparents, they experience fewer depressive symptoms. Although grandchildren from a variety of family constellations experience this benefit, grandchildren raised in single-parent families are particularly likely to experience decreased depressive symptoms as a result of having a close relationship with their grandparents. As this and other research suggests,

grandparents may play a protective role in that they may compensate for deficiencies in other arenas of their grandchildren's lives.

GRATITUDE

Gratitude is a common interpersonal emotion. Feeling grateful was the third most common discrete positive affect experienced in a sample of older adults, reported by nearly 90 percent of those surveyed. Gratitude can also represent a broader attitude toward life—the tendency to see all of life as a gift. Gratitude thus has various meanings and can be conceptualized at several levels of analysis ranging from momentary affect to long-term dispositions. It has been conceptualized as an

emotion, an attitude, a moral virtue, a habit, a personality trait, and a coping response. The word *gratitude* itself is derived from the Latin *gratia*, meaning grace, graciousness, or gratefulness. All derivatives from this Latin root have to do with kindness, generousness, gifts, the beauty of giving and receiving, or getting something for nothing. This entry discusses why gratitude is important in human relationships and, more generally, in life itself.

Although a variety of life experiences can elicit feelings of gratitude, prototypically gratitude stems from the perception that one has received a gift or benefit from another person. Grateful emotions and behaviors typically result from the perception that another person has intended to promote one's well-being. Most existing theories concur that gratitude is mostly under a specific set of attributions: (a) when a benefit is evaluated positively, (b) when the benefit that one has encountered is not attributed to one's own effort, and (c) when the benefit was rendered intentionally by the benefactor. Existing research suggests that gratitude is a typically pleasant experience that is linked to contentment, happiness, and hope. There is consensus that gratitude can be regarded as a moral emotion in that it leads to behavior intended to benefit others. The experience of gratitude results from acknowledging the "gratuitous" role sources of social support may play in propagating beneficial outcomes in our lives. Gratitude aids in reciprocating kindness toward those who have been kind to us.

Gratitude serves important functions in human's social and emotional lives. Recent work has suggested that gratitude is a reliable emotional response to the receipt of benefits, and that the experience and expression of gratitude may have important effects on behavior in the moral domain. From the perspectives of moral philosophy and theology, gratitude is seen as a human strength that enhances one's personal and relational well-being and is beneficial for society as a whole. Gratitude is a moral affect—that is, one with moral precursors and consequences. By experiencing gratitude, a person is motivated to carry out prosocial behavior, energized to sustain moral behaviors, and inhibited from committing destructive interpersonal behaviors. Specifically, gratitude serves as a *moral barometer*, providing individuals with an affective readout that accompanies the perception

that another person has treated them prosocially. Second, gratitude serves as a *moral motive*, stimulating people to behave prosocially after they have been the beneficiaries of other people's prosocial behavior. Third, gratitude serves as a *moral reinforcer*, encouraging prosocial behavior by reinforcing people for their previous good deeds. Gratitude is also motivating. There is an energizing and motivating quality to gratitude. It is a positive state of mind that gives rise to the "passing on of the gift" through positive action. As such, gratitude serves as a key link in the exchange between receiving and giving. This is a response to kindnesses received, as well as a motivator of future benevolent actions by the recipient. In the language of evolutionary processes, gratitude leads to "upstream reciprocity." As much of human life is about giving, receiving, and repaying, gratitude is a pivotal concept for human social interaction. Moreover, gratitude may spur spontaneous acts of altruism.

Gratitude Interventions and Subjective Well-Being

From ancient scriptures to modern devotional writers, counting blessings is frequently recommended as a strategy to improve one's life. Considerable research has examined the ability of gratitude to produce positive psychological, interpersonal, and physical outcomes. Experimental studies use random assignment to gratitude-inducing conditions and control groups. Gratitude interventions have shown that undergraduate students, adults with neuromuscular diseases, clinical patients suffering from depression, and school-aged children have benefited from increased gratitude in their lives. Gratitude interventions, by increasing the intensity and frequency of grateful emotions, have been shown to have sustainable effects on emotional and interpersonal well-being, as well as physical health. For example, research has found that those who kept gratitude journals on a regular basis exercised more regularly, reported fewer physical symptoms, felt better about their lives as a whole, and were more optimistic about the upcoming week compared with those who recorded hassles (every complaint and annoyance) or neutral life events. Those keeping gratitude journals also reported higher levels of high

engagement positive emotions, such as interest, excitement, enthusiasm, and vitality. A gratitude intervention with schoolchildren resulted in those keeping gratitude journals feeling significantly more optimistic about their upcoming week compared with those who recorded hassles. The gratitude condition also elicited greater satisfaction with school compared with both the hassles and control condition. Similar to adults, counting one's blessings seems to be an effective intervention for well-being enhancement in early adolescents.

Expressing gratitude for life's blessings—that is, a sense of wonder, thankfulness, and appreciation—is likely to elevate happiness for a number of reasons. Grateful thinking fosters the savoring of positive life experiences and situations, so that people can extract the maximum possible satisfaction and enjoyment from their circumstances. Counting one's blessings may directly counteract the effects of hedonic adaptation, the process by which our happiness level returns, again and again, to its baseline, by preventing people from taking the good things in their lives for granted. If we consciously remind ourselves of our blessings, it should become harder to take them for granted and adapt to them. And the very act of viewing good things as gifts itself is likely to be beneficial for mood. Additionally, there are interpersonal benefits to feeling grateful. When feeling grateful, people feel closer and more connected to others, and less lonely and isolated. As a social emotion, expressions of gratitude are essential to successful, vital, and thriving long-term relationships.

Gratitude as a Trait

The grateful disposition is a generalized tendency to recognize and respond with positive emotions (appreciation, thankfulness) to the role of other's benevolence in the positive experiences and outcomes that one obtains. A self-report measure of gratitude as a personality disposition has been constructed. Items on the Gratitude Questionnaire reflect gratitude intensity (e.g., "I feel thankful for what I have received in life"), gratitude frequency (e.g., "Long amounts of time can go by before I feel grateful to something or someone," scored in the negative direction), gratitude span (e.g., "I sometimes feel grateful for the smallest things"),

and gratitude density (e.g., "I am grateful to a wide variety of people"). These individual difference measures emphasize the emotional component of gratitude more so than the moral component of reciprocity.

People who score highly on measures of gratitude as an affective trait tend to experience a high degree of life satisfaction and positive affects such as happiness, vitality, and hope. They also experience relatively low levels of negative affects such as resentment, depression, and envy and higher levels of prosocial behavior, empathy, forgiveness, religiousness, and spirituality. Among the Big Five personality traits, the grateful disposition is related most strongly to Agreeableness (positively) and Neuroticism (negatively). For people who are dispositionally prone to feel grateful, the amount of gratitude in their daily moods is determined so thoroughly by personality processes that their moods are resistant to the effects of gratitude-relevant daily life events (e.g., experiencing many discrete gratitude-eliciting events; experiencing gratitude to a large number of people) and their discrete emotional responses to these daily events (i.e., feeling intense episodes of grateful emotion in response). This suggests that gratitude interventions may be less effective in inducing grateful emotions in these people who are already prone to feeling gratitude.

Be it as a state or trait emotion, gratitude has clearly been linked to subjective well-being. Indeed, happy people tend to be grateful people. They also tend to be more successful in their relationships. Moreover, expressing gratitude seems to intensify our already felt positive affect in response to being the beneficiary to a benefactor's kind behavior (e.g., giving a gift). Subsequently, capitalizing on positive experiences by dwelling on them seems to be psychologically beneficial. Indeed, the ability to notice positive occurrences in one's life and to enjoy them allows us to have more fulfilling experiences. Gratitude is easily cultivated and is efficacious in kindling positive emotions generally and appears also to stimulate prosocial behavior including willingness to become an organ donor.

Gratitude and Resilience

In addition to the positive benefits that can accrue from the conscious practice of gratitude, additional

studies have shown that gratitude can buffer a person from debilitating emotions and pathological psychological conditions. One study examined the frequency of positive and negative emotions before and after the tragic events of September 11, 2001. Out of 20 emotions, gratitude (for life and loved ones) was the second most commonly experienced (only compassion was rated higher). Positive emotions were critical characteristics that actively helped resilient people to cope with the September 11, 2001, disaster, suggesting another potential role that gratitude can play in interventions. Indeed, a whole line of research shows that benefit-finding can help people cope with disasters, deadly diseases, and bereavement. Even painful experiences can become something for which people are ultimately grateful. Thus, the regular experience and expression of gratitude can help build personal and interpersonal resources for coping effectively with stress and adversity.

Gratitude may also offer protection against psychiatric disorders. A factor-analytically derived measure of thankfulness (which included items explicitly related to gratitude, along with others that seemed to have more in common with love and acceptance) was associated with reduced risk for both internalizing (e.g., depression and anxiety) and externalizing (e.g., substance abuse) disorders in a study involving 2,616 male and female twins. So, gratitude may facilitate positive interpersonal functioning, and it appears to buffer against psychiatric disturbance and harmful interpersonal behaviors.

Some Obstacles to Gratitude

Any discussion of the benefits of gratitude would be incomplete without consideration of factors that render gratitude difficult. Scholars have suggested a number of attitudes that are incompatible with a grateful outlook on life, including perceptions of victimhood, an inability to admit to one's shortcomings, a sense of entitlement, envy and resentment, and an overemphasis on materialistic values. Some of these obstacles are likely to be deeply ingrained in personality. A major personality variable that is likely to thwart gratitude is narcissism. People with narcissistic tendencies erroneously believe they are deserving of special

rights and privileges. Along with being demanding and selfish, they exhibit an exaggerated sense of self-importance that leads them to expect special favors without assuming reciprocal responsibilities. The sense of entitlement combined with their insensitivity to the needs of others engenders interpersonal exploitation, whether consciously or unconsciously intended. In short, if one feels entitled to everything, then one is thankful for nothing. Interventions to cultivate gratitude cannot ignore these obstacles for it may be necessary to confront them on their own terms before initiating a gratitude focus.

Conclusion

In the history of ideas, gratitude has had surprisingly few detractors. Aside from a few harsh words from a small handful of cynics, nearly every thinker has viewed gratitude as a sentiment with virtually no downside. Andre Comte-Sponville, a philosopher, recently called gratitude "the most pleasant of the virtues, and the most virtuous of the pleasures." It is virtuously pleasant because experiencing it uplifts the person who experiences it and edifies the person to whom it is directed as well.

But that people typically consider gratitude a virtue and not simply a pleasure also indicates that gratitude does not always come naturally or easily. Gratitude must, and can, be cultivated. And by cultivating the virtue, it appears that people may get the pleasure of gratitude, and all of its other attendant benefits, thrown in for free.

The science of gratitude is still in its infancy, and much is not known. A distinguished emotions researcher recently commented that if a prize were given for the emotion most neglected by psychologists, gratitude would surely be among the contenders. Basic issues, such as the emotional structure of gratitude; its uniqueness from other positive emotions; the consequences of its experience and expression for emotional, physical, and relational well-being; and the cognitive mechanisms that build and sustain gratitude over time require further study.

GROUP DYNAMICS

Many of the interpersonal relationships that link people to one another are initiated by and organized within groups. Cliques, teams, crews, families, gangs, peer groups, military squads, professional associations, clubs, congregations, and the like are all groups, for they are networks of interdependent individuals with relatively well-defined boundaries and stable memberships. Groups, in many cases, are the wellsprings of relationships, for by joining a group, one becomes linked interpersonally to the other members of that group. These relationships,

however, are rarely static. Just as the dynamic processes that occur in groups—communication among members, shifts in influence and power as members vie for social status, pressures put on individual members to adhere to the group's standards, the eruption of conflict and discord as members find that others do not share their beliefs or interests—change the group, so they also change the relationships among members that the group sustains. This entry examines the role groups play as a source of enduring and significant human relationships, as well as the significant impact of group dynamics on those relationships.

Memberships as Relationships

The basic unit of analysis in relationship research is the dyadic pairing—the one-to-one link of one person to another. Individuals in a dyadic relationship—a father and son, two lovers, a leader and a follower, a teacher and student, two best friends—are interdependent: Their actions, affect, and cognitions are causally interconnected. These causal connections, or ties, may be strong emotional bonds, such as the links between members of a family or a clique of close friends. The links may also be relatively weak ones that are easily broken with the passage of time or the occurrence of relationship-damaging events.

When two people join in a dyad, an elemental group comes into existence. Although many of the features of larger groups, such as coalition building, shifting exclusions, and hierarchy, are necessarily absent in such groups, the dyad nonetheless includes many defining features of a group: interaction between the members; interdependence as members influence other's thoughts, actions, and emotions; patterning of behaviors over time and situations; shared goals; and a sense of inclusiveness.

As groups grow in size, the number of relationships that sustain the group increases. The maximum number of relationships within a group, where everyone is linked to everyone else, is given by the equation $n(n-1)/2$, where n is the number of people in the group. Only one relationship is needed to create a dyad, but the number of links in a group increases exponentially with increases in group size. Ten links, for example, are needed to

join each member of a 5-person group to every other member, 45 for a 10-person group, and 190 relationships for a 20-person group. In consequence, many ties between members in groups are indirect. Persons A, B, and C might all be group members, but A's influence on C is always mediated by person B. In groups, too, members may feel as though they are tied to specific members, to smaller cliques of members, and to the group as a whole.

In many cases, groups are created deliberately when people realize that they must collaborate with others to accomplish desired goals. Groups also come into existence, sometimes unexpectedly, when formerly independent, unrelated individuals, prompted by their personal needs or the press of environmental and social circumstances, seek a connection to others. Groups may, for example, emerge gradually over time as individuals find themselves interacting with the same subset of individuals with greater and greater frequency. These repeated associations may foster feelings of attraction, as well as a sense of shared identity as the interactants come to think of themselves as a group and people outside the group begin to treat them as a group.

Groups also tend to grow in size and complexity over time, as more members are added through both deliberate and spontaneous elaboration. A dyad may remain a two-person group throughout its duration, but more typically, groups grow in size as the core seed group establishes relationships with other individuals. A clique of adolescents, for example, forms when two friends are joined by two other individuals and they begin to recruit other friends to join the group. Groups also form when otherwise unrelated individuals are drawn to a single individual who becomes the informal leader, or hub, for gradually developing bonds among the various members.

The same factors that influence the development of such personal relationships as friendships and romances also influence the formation of member-to-member relationships. Just as people form romantic relationships with those who are similar to them, they also join groups comprising others who are similar to them. These similarities include psychological qualities, such as attitudes, values, and beliefs, but also categorical and demographic characteristics, such as

race, ethnicity, sex, and age. Members also tend to have similar individual and group level goals; they are each seeking their own individual outcomes and accomplishments, but they are also unified in their pursuit of shared collective outcomes. Groups, therefore, tend to be homogenous rather than heterogeneous—birds of a feather flock together even in human groups. Diversity actually tends to reduce the overall cohesiveness of a group, even though it may increase a group's creativity and efficacy in dealing with complex problems that require a range of experiences and expertise.

Interdependence Theory's emphasis on the economics of membership—the rewards and the costs of membership in a particular group relative to membership in alternative groups—suggests that people join groups that provide them with the maximum level of valued rewards while incurring the lowest level of costs. Rewards include acceptance by others, camaraderie, assistance in reaching personal goals, developing new interests, social support, exposure to new ideas, and opportunities to interact with people who are interesting and attractive. But groups have costs as well: time, money, exclusion by other group members, forced association with individuals—both within the group and in other groups—who may not be particularly likable, and the occasional need to modify one's personal preferences to conform to the dictates of the group. As with other types of personal relationships, individuals are more satisfied with a group if the rewards outweigh the costs, but degree of investment in the group (commitment) and the value of alternative group memberships are also critical variables that must be considered when predicting one's willingness to continue as a group member. When members feel as though they have invested a great deal of themselves in their group, perhaps because they have been a member for a prolonged period or because they have expended considerable personal costs to gain membership, then they are loath to terminate their membership even when the value of the group (the rewards relative to costs) declines. Individuals are also likely to remain in the group when they have no alternative; in most cases, membership in a group of low worth is psychologically more satisfying than membership in no group at all.

Group Dynamics and Relationships

Groups create relationships between members and substantially influence the nature and duration of those relationships. Group dynamics are the influential actions, processes, and changes that occur within and between groups over time. These dynamic processes change the group in predictable ways, and these changes naturally affect the relationships among the members of the group.

Early in the life of the group, *formative processes* strengthen the relationships that link members to one another. Initially, individuals may be unwilling to disclose personal information to others and may feel little loyalty to the group and its members. As the group becomes more cohesive, however, members may shift from the superficial and banal to more personal or even provocative topics. As members become acquainted with each other, they form general impressions of each other, and as they interact, each one in turn strives to make a good impression. Over time, as intimacy increases, group members express their trust in and commitment to the group, with the result that the group becomes more cohesive. Group cohesion is the integrity, solidarity, or unity of the group and tends to be closely linked to the strength and durability of the relationships between the members. Members of cohesive groups express greater attraction toward one another, they are more satisfied with their membership, and they are likely to resist leaving the group. Members of cohesive groups also tend to categorize themselves as group members, and as a result identify strongly with the group and their fellow group members. These *social identity processes* result in changes in self-conception, as individuals increasingly think of themselves in ways that are consistent with their conception of the prototypical group member and less in terms of personal, idiosyncratic qualities.

Increases in the cohesiveness of the group generally go hand-in-hand with increased group structure, as members come to occupy specific roles within the group and norms emerge that provide standards for behavior. These *structural processes* organize the group's procedures, interaction patterns, and intermember relations. Distinctive networks of communication and interaction often develop in groups, as cliques or coalitions emerge within the group. This sociometric differentiation

means that some members of the group enjoy strong, positive interpersonal ties with others in the group, but others might become more isolated from others. Status differentiation in the group, in contrast, creates differences in power and influence. When first formed, group members may be equal in their capacity to influence other individuals and the group as a whole, but status-organizing processes tend to replace this egalitarian structure with a more hierarchical one. Particularly in larger groups, the role of leader develops as one or more individuals take on the responsibility for guiding other members, often by organizing, directing, coordinating, supporting, and motivating their efforts.

Social influence processes also significantly influence members' relation to each other and to the group. As interactions become patterned and members become more group centered, the pressure to conform becomes greater and individuals' resistance to these pressures becomes weaker. As a result, individuals often change when they join a group, as their attitudes and actions align to match those of their fellow group members. They are also more likely to conform to a group's judgment rather than risk ostracism or weakening their positive relations with others. In extreme cases, group members will perform behaviors that they would not otherwise undertake because they do not want to lose their group's approval.

Conflict processes are also omnipresent, both within the group and between groups. When conflict occurs in a group, the actions or beliefs of one or more members of the group are unacceptable to and resisted by one or more of the other members. These tensions tend to undermine the cohesiveness of the group as well as cause specific relationships within the group to weaken or break altogether. Many group and individual factors conspire to create conflict in a group, but the most common sources are competition, disagreements over the distribution of resources, power struggles, uncertainty and disagreement over a decision, and personal antipathies. As conflicts worsen, members shift from weak to strong tactics, and the group may break up into rival coalitions that embroil formerly neutral members in the conflict. Conflict also often generates strong emotions, with the result that members who were once friends may become partners in an escalating series of hostile verbal exchanges. If unresolved, the conflict may eventually result in

the dissolution of the group. Once the group disbands, all the relationship that the group created and sustained may be severed, but more likely, the members will manage to create a newly configured group that does not include those who are thought to be the primary sources of the tension.

Groups and Relationships

Membership in a group creates significant and far-ranging interpersonal consequences for members. Fleeting, impersonal associations do little to meet people's need for meaningful connections with others, but membership in groups that create stable, reliable alliances among members—neighborhoods, cliques of coworkers, athletic teams, social clubs, and the like—is associated with gains in well-being and resilience to stress. Moreover, even though group membership is not often considered as essential a type of interpersonal relationship as are friendship and love relationships, people in groups can, in time, become so intimately connected that these relationships become the psychological equivalent of intimate relationships. Groups can be the source of distress and disappointment for their members, but they also securely link individuals together in a complex web of social relationships. As social creatures, individuals are embedded in a rich network of mutual, collective, and reciprocal group relationships; thus, individuals' actions cannot be understood fully without considering the groups to which they belong.

GUILT AND SHAME

Shame and guilt are members of a family of self-conscious emotions evoked by self-reflection and self-evaluation. People feel shame, guilt, or both when they fail, sin, or cause harm to another person. As a result, shame and guilt are often referred to as “moral” emotions because of the presumed role they play in fostering moral behavior. Although both are negative emotions precipitated by failures and transgressions, shame and guilt are not synonymous. Research suggests guilt is the more adaptive emotion, benefiting relationships in a variety of ways. In contrast, shame brings with it hidden costs that may actually interfere with interpersonal relationships. This entry begins with an overview of the difference between shame and guilt, followed by a discussion of the adaptive nature of guilt, and the maladaptive nature of shame. We conclude with a discussion of group-based shame and guilt.

What Is the Difference Between Shame and Guilt?

People often use the terms *guilt* and *shame* interchangeably. But recent research indicates these are distinct emotions. Some theorists have suggested shame is a more “public” emotion, arising from public exposure and disapproval, whereas guilt is a more “private” experience arising from self-generated pangs of conscience. As it turns out, research has not supported this public-private distinction regarding the actual characteristics of emotion-eliciting situations. For example, when researchers analyze people's descriptions of personal shame and guilt experiences, shame-inducing behaviors are no more likely to occur in public than are guilt-inducing behaviors.

Where does this notion that shame is a more public emotion come from? Although shame- and guilt-inducing situations are equally public in the likelihood that others are present and aware of one's failure or transgression, people pay attention

to different things when they feel shame compared with when they feel guilt. When feeling guilt, people are apt to think about their effects on others (e.g., how much a careless remark hurt a friend or how much they disappointed their parents). In contrast, when feeling shame, people are more inclined to worry about how others might evaluate them (e.g., “Do others think I’m a jerk?” “Do my parents see me as a failure?”). In short, when feeling shame, people often *focus* on others’ evaluations, but *actual* public exposure isn’t any more likely than in the case of guilt.

Another basis for distinguishing shame and guilt, and the distinction most strongly supported by social psychological research, centers on the *object* of one’s negative evaluation. According to this view, when people feel guilt, they feel badly about a specific *behavior*. When people feel shame, they feel badly about *themselves*. This differential emphasis on self (“*I* did that horrible thing”) versus behavior (“*I did* that horrible *thing*”) may seem minor, but it sets the stage for different emotional experiences and different patterns of motivation and subsequent behavior.

Shame is an especially painful emotion because one’s core self, rather than simply one’s behavior, is the issue. Shame involves painful scrutiny of the entire self, a feeling that “*I* am an unworthy, incompetent, or bad person.” People in the midst of a shame experience feel worthless, powerless, and “small.” When feeling shame, people are actually inclined to adopt a “shrinking” posture, as if they wish they could just disappear.

Guilt, on the other hand, does not affect one’s core identity because the focus is on a specific behavior, rather than the self. Guilt involves a sense of tension, remorse, and regret over the “bad thing done.” People in the midst of guilt are often preoccupied with the transgression, replaying the experience over and over again, wishing they had behaved differently. Rather than encouraging escape and avoidance, guilt motivates reparative behavior such as confessions, apologies, and attempts to fix the situation to undo the harm that was done, which is more likely to result in better outcomes.

Shame-Prone and Guilt-Prone Individuals

People react differently in similar failures or transgressions. Although most people have the capacity

to experience both shame and guilt, some people are more inclined to feel guilt, whereas others are more inclined to feel shame. For example, a shame-prone person might feel intense shame upon learning her scathing e-mail about office politics was mistakenly sent to her boss. In response to such a transgression, a shame-prone person might brand herself worthless and avoid her boss, possibly even missing work as a means of escape. A guilt-prone person, on the other hand, might respond to the same transgression with profound guilt. Such a person would be inclined to focus on the specific behavior, thinking about it over and over, feeling a sense of tension, remorse, and regret. In turn, this focus on the behavior is likely to prompt efforts to make amends with the boss, possibly by writing an apology or addressing concerns in a more appropriate forum.

Guilt as More Adaptive Moral Emotion

On the whole, guilt appears to be the more adaptive emotion, benefiting individuals and their relationships in a variety of ways. The following is a summary of the research literature in five areas—motivations, empathy, aggression, moral behavior, and psychological adjustment.

Hiding Versus Amending

Research consistently shows shame and guilt lead to different motivations or “action tendencies.” Shame has been linked with efforts to deny, hide, or escape the shame-inducing situation. Guilt, on the other hand, has been linked with reparative action—confessing, apologizing, and undoing. For example, when people are asked to anonymously describe personal shame experiences, they indicate they feel more compelled to hide from others and less inclined to admit what they had done, compared with when they feel guilt. In short, guilt motivates people in a constructive, future-oriented direction, whereas shame motivates people toward separation, distance, and defense.

Other-Oriented Empathy

Empathy is a highly valued emotional process that is an essential ingredient of warm, close interpersonal

relationships. Empathy motivates altruistic, helping behavior and inhibits antisocial behavior and aggression. Research indicates guilt and empathy go hand-in-hand, whereas shame is apt to disrupt an empathic connection. This differential relationship of shame and guilt to empathy has been observed at the levels of both emotion traits (dispositions) and emotion states. For example, researchers have consistently found, across various ages and demographic subgroups, that guilt-prone individuals express more adaptive forms of empathy, such as perspective taking and empathic concern, than do their less guilt-prone peers. In contrast, shame-proneness does not facilitate empathy. In fact, shame is more apt to be associated with personal distress (a self-oriented form of empathy).

Anger and Aggression

Based on her observations as a clinical psychologist, Helen Block Lewis first noted the relationship between shame and anger (or humiliated fury). She observed clients' feelings of shame often preceded expressions of anger and hostility in the therapy room. More recent empirical research has supported her claim. Studies of children, adolescents, college students, and adults have consistently shown proneness to shame is positively correlated with feelings of anger and hostility and an inclination to externalize blame.

Shame-prone individuals are more likely to externalize blame and anger but once angered, they are more likely to express their anger in a destructive fashion. For example, in a study of children, adolescents, college students, and adults, proneness to shame was consistently correlated with malevolent intentions, and a propensity to engage in direct physical, verbal, and symbolic aggression, indirect aggression (e.g., harming something important to the target, talking behind the target's back), all manner of displaced aggression (e.g., yelling at a roommate when an individual is actually angry at a professor), self-directed aggression, and anger held in (a ruminative unexpressed anger).

Shame and anger are similarly linked at the situational level. For example, in a study of anger among dating couples, shamed college students were significantly more angry, more likely to engage in aggressive behavior, and less likely to elicit

conciliatory behavior from their partners, compared with students not shamed. Described by some as a "shame-rage spiral," the findings suggest (a) shame can lead to feelings of irrational anger, (b) and destructive retaliation, (c), which can then prompt anger and resentment in the partner, (d) as well as expressions of blame and retaliation in kind, (e) which can then further shame the initially shamed person, reinitiating the cycle, and so forth—without any constructive resolution in sight.

In contrast, proneness to guilt is unrelated to anger. That is, guilt-prone people are no more or less likely to experience anger than are their peers. But once angered, guilt-prone individuals are inclined to manage their anger constructively, (e.g., engaging in nonhostile discussion or attempting to fix the situation), and they are disinclined to become aggressive.

Moral Behavior

Decades of research have failed to yield evidence for the "moral" self-regulatory nature of shame. Instead, recent research has linked shame with a range of illegal, risky, and otherwise problematic behaviors. In contrast, guilt appears to foster a lifelong pattern of generally following a moral path, motivating individuals to accept responsibility and take reparative action in the wake of the inevitable if only occasional failure or transgression. For example, one study found guilt-prone children were less inclined to become delinquent in adolescence than were their nonguilt-prone peers. Guilt-prone children were more likely to practice "safe sex" and less likely to abuse drugs. Even among adults already at high risk, guilt-proneness appears to serve a protective function.

Psychological Functioning

Finally, "shame-free" guilt is not associated with poor psychological adjustment or well-being, as Freud and Woody Allen would suggest. Research has found that, when differentiating between shame and guilt, the propensity to experience guilt is essentially unrelated to psychological symptoms. Numerous independent studies converge: shame, but not guilt, is consistently related to anxiety, depression, low self-esteem, and a host of other psychological problems.

When Does Guilt Become Maladaptive?

Why is guilt frequently cited as a symptom in such psychological disorders as anxiety and depression? What is the chronic, ruminative guilt described by so many clinicians? One possibility is many of these problematic guilt experiences are actually feelings of guilt *fused with feelings of shame*. It seems likely that when a person begins with a guilt experience (“Oh, look at what a horrible *thing* I have *done*”) but then magnifies and generalizes the event to the self (“ . . . and aren’t I a horrible *person*”), many of the advantages of guilt are lost. The person is faced with tension and remorse about a specific behavior that needs to be fixed, and he or she is saddled with feelings of contempt and disgust for a bad, defective self. In effect, shame-fused guilt may be just as problematic as shame itself. Research shows the unique variance in guilt (the part of guilt that is independent of shame) is most clearly related to positive interpersonal behaviors and adjustment. Co-occurring shame and guilt are associated with poor outcomes, much as is shame unaccompanied by guilt.

Vicarious, Group-Based, or “Collective” Shame and Guilt

Until recently, most research has focused exclusively on personal shame and guilt experienced in response to one’s *own* failures and misdeeds. A number of investigators have substantially expanded the literature on self-conscious emotions by considering vicarious or group-based shame and guilt—feelings experienced about the transgressions and failures of *other* individuals. According to Social Identity Theory, to the extent that the self is, in part, defined by interpersonal relationships and group affiliations, it is possible to construe the behavior of an ingroup member as reflecting on the self. Research findings on vicarious shame and guilt are similar in many respects to the research on personal shame and guilt experiences described thus far. For example, group-based guilt (feeling guilt for the behavior of an

ingroup member) has been associated with empathy and a motivation to repair or make amends. Vicarious group-based shame has been linked with anger and a desire to distance oneself from the shame-eliciting group or event.

Scientific study of shame and guilt is a relatively recent endeavor, and much remains unknown. The next generation of research on these moral emotions will no doubt further incorporate other related fields to better understand the development of moral emotions and the neurobiological mechanisms by which they function, with the ultimate goal of translating this knowledge into action for the good of society.

H

HAPPINESS AND RELATIONSHIPS

Social relationships are often described as the most important factor in determining a person's happiness. If there is a single characteristic that best distinguishes people who are extremely happy from everyone else, it appears to be the quality of their social relationships. People who are more satisfied with their relationships report higher subjective well-being and greater objective health—including longer lives and less vulnerability to illness. Although social processes are important to people's happiness, the causal arrow often points in the other direction, with happiness leading to stronger and more satisfying relationships. The links between happiness and social relationships also vary depending on the definitions being used to investigate the topic. Happiness is frequently thought to consist of separable elements: positive affect, negative affect, life satisfaction, and satisfaction with particular life domains (e.g., work). As for social relationships, research has focused on relationship quality and satisfaction, various positive and negative relationship processes, and different types of relationships. Furthermore, definitions and methodologies can moderate the magnitude (and sometimes the direction) of relations between happiness and social relationships. This entry reviews research on relationships and happiness, and discusses implications for social policy and future research.

General Findings

Sociability

The degree to which people are sociable is one of the strongest predictors of frequent positive affect and life satisfaction. Researchers have used experience-sampling methodologies to collect information from people during in vivo social events. Typically, respondents are asked to complete a series of questions at random moments or immediately after every social interaction that lasts at least 10 minutes. By collecting comprehensive information about how people think and behave in their natural environment, researchers can examine factors that might influence the benefits of socializing. Most people—including those who are shy or introverted—consistently report greater positive affect when socializing compared with being alone. Similarly, people who spend a greater percentage of their time with others report being more satisfied with their lives. In the few longitudinal studies on the topic, being more sociable (as defined by self-reported talkativeness, assertiveness, and preferences for social gatherings) leads to greater happiness over time and, in turn, people experiencing more positive affect report larger and higher quality social networks across time.

The link between relationships and happiness is more modest, but still meaningful, when examining behavior in the laboratory. When talking to strangers, for example, research participants reporting being happier are observed to smile more

frequently and be more talkative, energetic, and humorous. In turn, strangers perceive happier people as more likable and show a stronger interest in forming relationships with them. In other studies, people induced into good moods were observed to be more sociable when interacting with strangers and more likely to be talkative, responsive, and generous and to initiate humor. The benefits of social interactions tend to be stronger when they are less formal and relatively unstructured.

The studies reviewed focused on positive affect and life satisfaction as markers of happiness that are moderately correlated with various social outcomes. That said, it should not be inferred that negative affect is associated with lesser sociability. Recent evidence shows that positive and negative emotions are distinct psychological and neural systems, so that the correlation between measured positive and negative affect is often minimal. Furthermore, a substantial literature indicates that negative affect is not related to the size of a person's social network, frequency of naturally occurring social interactions, or overall social activity. When getting acquainted with strangers, the average person experiences a surge in positive affect but no change in negative affect. In specific cases, however, stressful and hurtful social interactions can lead to profound increases in negative affect, and in turn, people suffering from depression and other emotional disturbances often behave in ways that lead to social rejection.

There is evidence for bidirectional relations between happiness and sociability. This conclusion, however, is tempered by important contextual influences. When happiness is defined by positive affect or life satisfaction, moderate to strong relations emerge with various measures of social activity. Negative affect is generally unrelated to social activity. In addition, not all social activities are equivalent. For example, taking part in highly structured social interactions and spending time with others during sedentary activities are typically unrelated to markers of happiness.

Real-World Relationships

How do different types of relationships influence happiness? Evidence indicates small positive correlations between frequent, intense positive emotional experiences (called *trait affect* by

researchers) and marital satisfaction, the number of close relationships a person has, and the frequency of contact with these individuals. These correlations are larger in magnitude when family members are excluded and the focus is on friends and other self-selected relationships. Some studies show that people are happier when they are with friends compared with strangers or family members or are alone. Thus, although family relationships are associated with each element of well-being across the life span, friendships appear to be more important.

Perhaps the primary exception to this generalization is early parent-child attachment bonds. The presence of a warm, enduring relationship with a caregiver early in life promotes happiness and success in life. The quality of parent-child relationships predicts high levels of emotional adjustment, social competence, and life satisfaction. The underlying mechanisms appear to be bidirectional because parents with emotional difficulties and dissatisfied lives are also less likely to form strong, secure bonds with their children.

Sexuality and the intimate connections that characterize romantic relationships are uniquely relevant to psychological well-being. Generally, married people are happier than are single adults who, in turn, are happier than are those who are divorced or widowed. Yet these results often ignore context. For example, when people are highly satisfied in their marriages, their general life satisfaction often surges upward. In contrast, problematic, conflict-laden relationships lead to infrequent positive affect, frequent negative affect, and disruptions in life satisfaction. Another important contextual factor is the nonrandom selection of romantic partners. People often choose spouses based on desirable personality traits that are readily apparent before marriage. In longitudinal studies, for example, people who are generally happy are more likely to have satisfying marriages whereas people who eventually divorce show lower levels of happiness even before their relationships had begun. This fits with the larger body of research showing that happier people engage in social behaviors that foster healthy relationships including altruism, generosity, affection, empathy, responsiveness, cheerfulness, and supportiveness.

Although there are fewer studies on relationships within organizational settings, happier people

also exhibit better relationships at work. These positive relationships translate into greater productivity and work satisfaction and a sustainable source of meaning and life satisfaction. Thus, it appears that the degree to which a person is happy has direct implications for the health of families, work environments, and communities. Preliminary evidence for these types of societal benefits can be found in the fact that even in economically disadvantaged communities, strong social relationships may buffer the dire effects of poverty.

Evolutionary and Biological Perspectives

Human beings, like our primate cousins, are social animals who naturally dwell together in family units and larger communities. Social relations appear to be fundamental to human adaptive evolution as evidenced by kin selection, specific neural circuitry for recognizing faces, moral social norms (such as those related to obedience and reciprocal altruism), and a wide variety of important social and psychological mechanisms. If sociability is, in fact, an evolutionary advantage, then it is interesting to ponder how happiness might be implicated in this process.

Historically, emotional states have been viewed as instrumental to survival. For example, negative emotional states such as fear are thought to improve survival in threatening situations by limiting thoughts and actions, leading to rapid responding. Positive emotional states are thought to accompany nonthreatening situations and promote social coalition building, personal skill development, and a variety of expansive cognitive and behavioral repertoires. Joy, specifically, has been found to promote playfulness, which, in turn, facilitates better relationships. Thus, happiness appears to be a critical element for human survival because it leads directly to helping others, engaging in group recreation, and a propensity to form mutually beneficial social coalitions.

Preliminary evidence also indicates a beneficial, direct link between specific neurological activity and social relationships. For instance, the hormone oxytocin is released during intense social interactions and appears to facilitate pair bonding. This hormone stimulates feelings of joy and love and initiates behaviors such as affection and caretaking.

Oxytocin further interacts with opioids to attenuate psychological and biological stress responses. During stressful situations, the release of oxytocin leads to social support seeking and nurturance behaviors. As evidence of its role in strengthening social bonds, oxytocin is released by mothers when breastfeeding infants and by adults when engaged in sexual acts. Interestingly, the effects of oxytocin depend on an animal's social role. Oxytocin makes dominant animals more aggressive and hypersexual whereas submissive animals become more affiliative and acquiescent. Essentially, oxytocin modifies emotions, cognitions, and behaviors to increase the likelihood of strong, functional social bonds (there are diverse paths to reaching these social bonds). One of the hormone's by-products appears to be an increased ability to form satisfying relationships and find happiness.

A Note About Culture

Culture is a fundamental social construct that plays an interesting role in the link between social relationships and happiness. Several researchers have identified areas in which cultural norms influence happiness. For example, cultural factors influence how individuals value and define the experience of happiness itself. Asian cultures, for instance, place a premium on low-arousal positive emotions such as peace and contentment, whereas individualists in many Western cultures prize high arousal positive emotions such as exuberance and joy. Researchers have found that parental expectations influence individual happiness and that these differ across cultures. Similarly, some cultures appear to value mastery over enjoyment, and individuals in these cultures are more likely to sacrifice short-term happiness for long-term achievement. Taken together, the research on culture and happiness indicates that cultural processes are an important moderating variable.

Important Caveats

Despite research findings indicating that social relationships play an important—if not central—role in personal fulfillment, there are several important caveats. First, most of the research on

happiness and relationships is correlational and, therefore, causal directions remain uncertain. Second, relationships may also have psychological costs. For example, empathic responses to friends and family members can lead to personal distress (e.g., when witnessing a friend experience hardship), guilt (e.g., when one has hurt a loved one), or a lack of sense of self (e.g., when attempting to meet the needs of others at the expense of unmet personal needs). Although close personal relationships usually come with a variety of benefits, heavily investing in others can have drawbacks if that person leaves or betrays the relationship. For example, research on the happiness of widows suggests that the average widow may take years after her spouse's death to regain former levels of life satisfaction. Finally, it should be noted that whereas relationships generally promote happiness, and vice versa, this connection depends on the type of relationship. There is evidence of gender differences, with women deriving greater benefits from social affiliation and support but less happiness in marital relationships compared with men. The relation between happiness and social ties also may differ based on the specific type of relationship under consideration (e.g., family, work, friends). Thus, caution is warranted in assuming that relationships universally promote happiness.

HARD-TO-GET PHENOMENON

The *hard-to-get phenomenon* refers to the notion, held across diverse cultures and espoused by sources ranging from Socrates to Ovid to the *Kama Sutra*, that individuals experience greater attraction to a person who is or seems difficult to attract than to a person who is or seems easy to attract. Although theorizing on the hard-to-get phenomenon dates back to ancient times, the phenomenon did not receive empirical attention until the 1970s. This entry briefly reviews and evaluates the empirical research on the hard-to-get phenomenon in romantic contexts.

Laboratory Experiments

In 1973, Elaine Hatfield (formerly Walster) and her colleagues published a series of six experiments designed to test the hypothesis that hard-to-get women are more romantically desirable to men than are easy-to-get women. The first five experiments uniformly failed to provide any evidence in support of the notion that hard-to-get women are more attractive than easy-to-get women. In one study, for example, women who initially declined a date with a man before eventually accepting it were no more or less desirable to

the man than women who eagerly accepted the date right away. After these five failures, Walster and colleagues went back to the drawing board and recognized that there are actually two distinct ways in which a man can think of a woman as being hard to get: (1) how hard it is for *me* to get her and (2) how hard it is for *other men* to get her. The scholars hypothesized that men would be most attracted to the woman who is *selectively* hard to get—easy for them to get but hard for other men to get.

In a sixth study, college-aged men evaluated the desirability of five college-aged women who had ostensibly matched with them through a dating service. (In reality, these women's profiles were created by the researchers.) The experimenter explained that three of the five women had previously attended a session in which they had completed five "date selection forms," one for each of their five male matches. For each of these three women, the participant saw that one form included ratings of himself and the other four forms included ratings of fictitious men. One of these women was *uniformly hard to get*, rating all five of her matches as not especially appealing. One was *uniformly easy to get*, rating all five of her matches as highly appealing. And one was *selectively hard to get*, rating the other four men as unappealing but rating the male participant as highly appealing.

The men exhibited an overwhelming preference for the selectively hard-to-get woman. She was the top choice of 59 percent of them, with each of the other four women (including the two who ostensibly had not yet completed their date selection forms) winning top-choice honors from only 7 to 15 percent. The men viewed this woman as having all of the advantages of her competitors, but none of their liabilities. For example, they perceived her as being just as popular as the uniformly hard-to-get women (while being less cold) and just as friendly as the uniformly easy-to-get woman (while being more popular). Subsequent research including both men and women participants revealed a second reason why selectively hard-to-get individuals are so desirable: Being liked by such individuals raises one's self-esteem.

The notion that people who are selectively hard to get are especially desirable has gone largely unchallenged, but a series of studies from the mid-1980s partially resurrected the notion that

being uniformly hard to get (or at least not being uniformly easy to get) can also inspire others' romantic interest. In contrast to the studies by Walster and colleagues, participants in these subsequent studies learned how *generally* selective a target person was—that is, without the target directly evaluating the self. Participants found targets who were moderately to strongly hard to get more desirable than targets who were easy to get in these circumstances where personal rejection was no longer implied by the hard-to-get manipulation.

Recent Real-World Evidence

Recent research by Paul Eastwick and colleagues has sought to extend research on the hard-to-get phenomenon beyond the laboratory. Scholars employed speed-dating procedures to test whether people are attracted to others who are selectively hard to get, uniformly hard to get, or both. Men and women participants completed a brief questionnaire after each of their 12 speed dates, indicating the degree to which they experienced romantic desire for that partner.

Two key results emerged. First, when a speed dater found one of the partners more desirable than the others, that partner tended to reciprocate this unique liking. This finding is consistent with the well-validated notion that people are attracted to others who selectively like them. Second, when a speed dater tended to find all of the partners desirable, those partners tended *not* to find him or her desirable in return. This finding is consistent with the notion that people are not attracted to others who are uniformly easy to get; instead, they prefer somebody who is uniformly hard to get. This study suggests that being uniformly hard to get might make individuals more desirable, but peppering one's selectivity with unique liking for a particular partner will enhance the degree to which that partner desires the self.

Conclusion

Overall, the laboratory and speed-dating studies provide robust evidence that people tend to be attracted to selectively hard-to-get others (those who uniquely like the self). These studies are less

definitive in discerning whether people tend to be more attracted to others who are uniformly hard to get than to others who are uniformly easy to get, but preliminary evidence from real-world dating encounters suggests that there may be some truth to the notion that uniformly hard-to-get people are especially desirable after all.

HEALTH, RELATIONSHIPS AS A FACTOR IN TREATMENT

Close relationships such as marriage can have either a positive or negative impact on an individual’s successful adjustment to and management of a chronic health condition. Because of this influence of family on health, researchers have developed family-oriented, psychosocial, or behavioral treatments to supplement the medical care received by the ill individual. This entry describes the reasons that relationships are important to consider in the treatment of chronic illness in adulthood, the different types of family-oriented treatments, and the evidence for the effectiveness of these treatments.

Why Are Relationships Important in the Treatment of Health Conditions?

The rationale for involving a family member in treatment can be found in the biopsychosocial model of health and illness, specific marital and family systems frameworks, and family caregiving and care-receiving models. These theoretical frameworks have been supported by empirical evidence that close social relationships affect biological systems, health behaviors, and psychological well-being. Specifically, emotionally and instrumentally supportive actions by family members, as well as family conflict and criticism, affect immune function, blood pressure, and depressive symptoms, as well as future illness events (e.g., recurrence of cancer, myocardial infarction). Family members’ attitudes toward illness and their own health behaviors also affect patients’ decisions to follow recommendations for medical treatment and their ability to initiate and maintain difficult changes in diet and exercise.

Many of the linkages between family and health have been observed across chronic conditions as diverse as heart disease, chronic pain disorders, arthritis, Type 2 diabetes, renal disease, breast cancer, and spinal cord injury. An example of positive associations between family and health is the finding that individuals with Type 2 diabetes who have more supportive families are also more adherent over time for glucose testing, insulin injection, and a dietary regimen. In addition, for people with end-stage renal disease who are undergoing hemodialysis, greater perceived family support has been associated with greater psychological well-being, adherence to fluid-intake restrictions, and survival at a 5-year follow-up. To provide an example of negative associations between family and health, interpersonal conflict has been linked with greater disease activity (e.g., joint swelling) in people with rheumatoid arthritis.

In turn, physical illness can take a toll on patients’ close family members. Patients’ illness symptoms, negative mood, and need for emotional support or physical assistance often become taxing to family members over time. These experiences may result in family members’ psychological distress, decreased relationship quality with the patient, caregiving burden, and poorer physical health. These consequences are especially likely in

cases where the health condition is life threatening or results in a high level of dependency. For example, a study of recently hospitalized individuals with cancer showed that despite patients' improvement or stabilization after discharge, their family caregivers continued to experience high levels of psychological burden 6 months after patients' hospitalization. Spousal caregivers of individuals with Alzheimer's disease (AD) have been shown to have an impaired immune response to influenza virus vaccination, as well as impaired wound healing, in comparison with individuals who are not caregivers to a spouse with AD but similar to those caregivers in other ways (e.g., age, gender).

A logical conclusion that can be drawn from this body of research is that incorporating a close family member in a psychosocial or behavioral treatment for chronic illness may have a positive impact on the patient as a result of enhancing the family member's empathy and supportiveness. The family member may also become more helpful in practical ways such as monitoring the patient's blood pressure at home and providing more effective assistance with activities of daily living such as dressing, getting around the house, and managing medications. In addition, the family member is likely to experience decreased burden stemming from improvements in patient functioning, validation of caregiving experiences (i.e., confirmation that the illness is difficult for him or her, as well as for the patient), and improved interactions with the patient. In other words, the bidirectional links between health and family relationships suggest that family-oriented treatments may benefit the health and well-being of both patient and family member.

What Approaches Are Used to Involve a Close Family Member in Treatment?

Some researchers have developed dyadic treatments by modifying patient-focused treatments to include a family member, most commonly the spouse or an adult son or daughter. For example, weight loss programs for obese individuals with a chronic illness have been modified to include the spouse. Other researchers have developed caregiver treatments that are targeted solely at the family member on whom the patient primarily

depends for assistance support. For example, stress management skills training has been targeted at spousal caregivers to individuals with AD or stroke. Both of these approaches are family oriented in their focus on the patient's closest family member, either with or without patient involvement.

Family-oriented treatments are most commonly psychological, social, or behavioral in nature or use a combination of these approaches. Psychological approaches may include stress management skills training, or information about the illness and its treatment, and may be targeted at the dyad or the family member alone. Socially focused approaches often take the form of peer support groups (i.e., meeting with other dyads who are dealing with the same illness, or other family caregivers) or counseling aimed at maintaining or improving dyadic relationship quality in the face of illness. Behaviorally focused treatments are often aimed at getting both patient and family member to work together in creating a healthier lifestyle. In addition, these behavioral treatments may be aimed at changing family members' overly solicitous reactions to patients' pain or fatigue, such as jumping in to provide assistance with various tasks before such help is warranted or desired by the patient.

Family-oriented treatments for chronic illness also vary in how intensively they involve the family member. Some of the less intensive approaches may enlist the family member's help in monitoring the patient's health (e.g., blood pressure checks) or encouraging healthy behaviors, or provide the family member with information about the patient's illness (e.g., causes, symptoms, available medical treatments). In contrast, treatments that more intensively involve family may also target supportive and unsupportive communications within the dyad (e.g., counseling for couples dealing with the wife's breast cancer) or address the family member's burden and concerns.

Is Including Family in Treatment an Effective Approach?

Reviews of the research literature indicate that patients who receive family-oriented treatment in addition to usual medical care benefit more than

do patients who receive medical care alone. Specifically, treatments that include the spouse result in small, positive improvements in depressive symptoms across various illnesses. In addition, behaviorally focused, family-oriented treatments for individuals dealing with hypertension or cardiovascular disease result in a small decreased risk for mortality that outweigh the benefits of medical care alone. Some research has examined whether the family member also benefits from family-oriented treatment. These studies have shown that family members experience small improvements in how depressed or anxious they feel, and report less stress or burden from caregiving, in comparison with family members of patients who receive medical care alone.

Another question that researchers have tried to answer is whether patients who receive family-oriented treatment benefit more than do those who receive patient-oriented treatment (with both groups also receiving usual medical care). This research literature indicates that the advantage of family-oriented treatment over patient-oriented treatment for patient health and well-being is not yet clear, and the comparative benefits for family member health and well-being are rarely assessed at all. The advantage of one type of treatment over the other seems to depend on factors such as specific treatment approach. For example, studies focused on rheumatoid arthritis or osteoarthritis have shown that family-oriented treatments that use cognitive-behavioral approaches (e.g., training spouses to help patients change their negative ways of thinking about and responding to pain) rather than psychoeducational approaches (e.g., providing information to both partners about the illness and its treatment) result in greater reductions in patients' pain or joint swelling than cognitive-behavioral interventions for patients only. The advantage of family-oriented treatment over patient-oriented treatment may also depend on patient gender. For example, a couple-oriented behavioral program for obese individuals with Type 2 diabetes resulted in more weight loss for female patients than did a patient-oriented program, whereas male patients lost more weight in the patient-oriented program.

HEALTH AND RELATIONSHIPS

Relationships can be broadly defined by their structural components such as the simple existence of social ties (e.g., married, belonging to voluntary groups) and by their functional components for what they may provide us (e.g., sense of comfort, available support). The notion that health, which encompasses disease-related morbidity or

mortality, could be influenced by relationships is relatively new. For a century, the dominant approach to understanding health focused on physiological and pathogen-related contributions to disease. However, these types of explanations paint an incomplete picture of human health.

Recent interdisciplinary research is beginning to unravel the complex mysteries of disease by simultaneously considering relevant psychosocial risk factors. Of these risk factors, one of the most consistent predictors to emerge is the quality and quantity of one's social relationships. This entry summarizes general research findings, including how researchers define and measure relationships, data linking relationships to health, potential pathways responsible for such links, and intervention approaches.

What Do Researchers Mean by Relationships?

Research on social ties and health often defines relationships in different ways. A broad distinction between structural and functional aspects of relationships is common but within these categories are numerous exemplars. Structural measures often tap into the extent to which a person is situated or integrated into a social network. For instance, researchers may ask participants if they are married, how many family members they have contact with, or if they participate in any social activities. This work has its roots in the concept of symbolic interactionism, a social-psychological concept that highlights the importance of meaningful social roles in the development of one's identity. The use of structural measures has been the most long-standing (and popular) approach to examining links between relationships and health.

More recently, many studies examine relationships and health in terms of the particular supportive functions they serve. These functions are usually organized along two dimensions. One dimension is what support is perceived to be available. The other dimension is what support is actually received or provided by others. What is perceived as available may or may not correspond to what is actually provided. For instance, individuals who perceive support to be available may not actually seek support as a first coping option, and just knowing support is available may alleviate stress

because it acts as a "safety net." Therefore, both measurement approaches are important. So what exactly is made available or provided by supportive individuals? Many researchers argue that the types of support that may be provided are what can be termed *emotional* (e.g., expressions of caring), *informational* (e.g., information that might be used to deal with stress), *tangible* (e.g., direct material aide), and *belonging* (e.g., others to engage in social activities) support.

Recent research on relationships and health is moving toward a more comprehensive view of relationships that is affecting how we measure it. The most important trend is probably the explicit acknowledgement of the detrimental influences of negativity (e.g., conflict) in close relationships on health. Although this has long been acknowledged in the larger close relationships literature, its impact on the health literature has been less given the prior emphasis on support processes. However, considering negativity in relationships is important because conflict in stable, long-term relationships (e.g., marriage, family) can theoretically influence the development of chronic conditions that develop slowly over time (e.g., cardiovascular disease).

What Is the Link Between Relationships and Physical Health Outcomes?

A large body of epidemiological studies shows that both the quantity and quality of one's relationships influence disease morbidity and mortality. Most of these studies have focused on the positive aspects of relationships and were well-controlled, long-term studies with thousands of participants, which gives us greater confidence in their conclusions. In this literature, structural aspects of relationships, especially composite measures of relationships (indicating the existence of important social contact—e.g., marriage, family members) and participation in voluntary groups appear to be consistent predictors of lower all-cause mortality rates. It is thought that structural variables, such as participation in social groups, increases (a) access to support, (b) self-esteem, and (c) purpose in life. These factors, in turn, may decrease risk for mortality via enhanced coping with stress and greater efficacy and motivation to care for oneself. Strong evidence also indicates

that functional aspects of relationships, such as emotional support, predict lower all-cause mortality. For specific diseases, reliable evidence links relationships to cardiovascular disease outcomes. Preliminary evidence also points to the influence of structural and functional aspects of relationships on infectious disease risk, with more controversial links to cancer outcomes.

Although the general findings from this literature are on strong ground, several emerging issues deserve attention. First, evidence indicates that not all functional types of support are beneficial for health. Of these, emotional support appears the most beneficial, whereas there is a trend for individuals who receive relatively high levels of tangible support to have higher mortality. A simple potential explanation based on the concept of support mobilization is that individuals who are more dependent on receiving tangible support are also more physically impaired to begin with. However, studies do not appear to support this explanation as most considered the influence of initial health status or limitations in activities of daily living. Several potential viable explanations for this link (e.g., negative psychological effects of dependence, increases in conflict) are currently being evaluated.

A second issue is that relationships, although sources of support and caring, may also be linked to interpersonal conflict. Many of our relationships contain a mix of both positive and negative aspects, which is important because conflict may cancel out any benefits of relationships or be detrimental in their own right. Evidence links negativity in relationship, such as divorce or family conflict, to poorer health outcomes. The negative aspects of relationship are often not highly related to the positive aspects. As a result, high levels of positivity in a relationship do not imply that there are no important negative aspects. This issue will need greater attention in future research.

A third issue is a focus on the person perceiving or receiving support, as well as on the person providing it. Research typically emphasizes the detrimental influences of such roles (e.g., the burden experienced by caregivers of a family member with Alzheimer's disease). However, under more moderate levels of stress (or choice in pursuing the role), some recent studies have shown that individuals who are providers of support have lower all-cause mortality. This emphasis is important because

health-relevant relationship processes unfold in a dyadic (e.g., wife, husband) or group (e.g., family) context. The emphasis on individuals who provide support is a step in the direction of modeling more complex interpersonal processes.

What Are the Pathways Linking Relationships to Health?

One of the most important areas of research is focusing on how relationships are managing to influence such acute and chronic physical health outcomes. These pathways are being examined from an interdisciplinary perspective and can broadly be categorized as psychological, behavioral, and physiological in nature.

Many studies have examined links between relationships and psychological or mental health outcomes. However, direct examination of these outcomes as pathways in epidemiological studies is missing. Nevertheless, the larger literature on relationships and mental health can be used to inform future studies because there are a number of promising links. First, relationships may influence one's interpretation (appraisal) of a stressful situation so that its harmful influences are mitigated. For instance, knowing that you have individuals in your life who can provide emotional or informational support may help you feel more confident about dealing with stressful changes in life (e.g., job, family). This might also increase your feelings of mastery or control over life. Relationships also appear to protect one from depression and anxiety by serving as a potential resource during times of need. Finally, relationships can influence self-related processes such as one's identity via social roles or an affirmation of the self as competent and worthy (i.e., self-esteem). These psychological factors are important because they may be linked to physical health in their own right (e.g., depression) and, hence, are promising mediators for future research linking relationships to health. Modeling these and related psychological processes remains a high priority for relationships and health research.

The importance of behavioral pathways is highlighted by social control theorists who have shown relationships to be related to better health behaviors. For instance, relationships (e.g., being married, engaging in social roles) are generally related to

more exercise, better diet, and cooperation with medical regimens. Social control theorists argue that relationships are linked to such health behaviors because they provide us with important incentives to live. An example would be a father deciding to take better care of his health so he can see his child grow up. Such theorists also argue that relationships provide us with direct social control because spouses can impose sanctions on their significant others if necessary (e.g., refusing to talk to them if they do not see a doctor). The context of social control is important to consider as relationships may not always be linked to positive influences (e.g., peer influences on drug use).

The behavioral factors examined by social control theorists are attractive as potential pathways because they are risk factors for physical health problems in their own right. Indeed, research suggests that at least part of the link between relationships and physical health is explained by such health behaviors. However, many studies continue to simply statistically control for health behaviors (confound) in examining links between relationships and health despite its theoretical role as a pathway.

Finally, physiological processes are increasingly being modeled as pathways linking relationships to health. This is particularly important because it allows health-relevant “intermediate” outcomes that confer risk to later (or in some cases immediate) health problems. The largest literature links relationships to cardiovascular processes known to predict disease. This research suggests that individuals who have greater support in their lives appear to have lower resting blood pressure, cardiovascular reactivity, and ambulatory blood pressure. Recent research also highlights links to immune-mediated inflammatory responses. Such research is promising given its potential to integrate research on relationship and immunity to cardiovascular disease, but the small number of current studies do not allow for strong conclusions.

More general links between relationships and aspects of immune function that can influence infectious disease risk are on strong grounds. These studies examine the functional ability of immune cells to mount a response (e.g., natural killer cell activity, antibody titers to vaccination) and show that positive aspects of relationships

(e.g., emotional support) predict stronger functional responses. Likewise, social stressors (e.g., marital conflict) appear to have detrimental influences on functional immune responses.

There is less research examining links between relationships and neuroendocrine pathways. Sufficient studies, however, exist suggesting social support is related to lower cortisol levels, whereas social conflict (e.g., marital) is linked to higher cortisol levels. These findings are important because cortisol has well-documented immunosuppressive effects. Future research on neuroendocrine pathways will be important because such hormones influence both cardiovascular and immune function. In the absence of such research, researchers will have difficulty modeling potential cascading links between physiological systems that ultimately compromise physical health.

A final physiological pathway starting to receive attention is seen in studies that use sophisticated imaging techniques to examine brain activity as a function of relationships. These studies complement work on psychological and biological pathways; preliminary evidence links relationships to lower activation of stress-related areas of the brain. Although only a few studies now exist, such research promises a more integrative picture of how relationships influence the central nervous system, with direct links to peripheral “downstream” health-related alterations.

Can This Work Inform Relevant Interventions?

Research on relationships and health is stimulating much interest in relevant interventions. Would it be possible to teach individuals to access their existing relationships in a way that is health-promoting? As it turns out, there is already an extensive literature on relationship-based interventions (e.g., marital, family, support) that differ in their focus depending on the relationship or disease context. Most of these relationship interventions that focus on health attempt to foster adjustment more generally in chronic disease populations such as cancer or HIV patients. Many of these interventions also do not directly focus on physical health but more on mental health (e.g., depression) and relevant behavioral change (e.g., smoking cessation).

Even these health-oriented support interventions differ dramatically in their approach and orientation. Benjamin Gottlieb proposed one widely used categorization scheme. He argued that support interventions can be categorized along two dimensions based on the provider of support. The first dimension has to do with the nature of the relationship between the support provider and participant. Is the support provider a newly formed relationship (e.g., practitioner, peers) or does it involve already established relationships from a person's existing support network? The second dimension focuses on the unit of support. Is support provided in a one-on-one setting or is it provided in a group setting?

Based on this typology, there are several types of relationship-based interventions in health research. The first type involves support from professionals. Such individuals can be good sources of support given their expertise in the disease context. These interventions often take the form of doctors, nurses, or other health educators who provide the patient with informational, but in some cases, emotional support. These interventions appear promising in fostering adjustment in disease populations, especially those involving educational interventions. However, some inconsistencies in this literature may be the result of the diverse patient populations examined who may have differing needs.

A second type of intervention with new relationships is grounded in peer support groups. In such interventions, a professional is often utilized to guide discussion but the focus is on what each member brings to the group context. An important guiding principle is based on experiential similarity in which members share a common basis (e.g., Alcoholics Anonymous; cancer support groups). The potential importance of such peer support groups in the health domain was spearheaded by the well-known results of David Spiegel's intervention in the 1980s, which found that cancer patients lived longer if they were in support groups. Recent evaluations of peer support groups have failed to replicate this effect on survival (perhaps due to less stigma and the greater support now available to cancer patients)—but continue to document positive influences on mental health outcomes. In general, such peer support interventions appear to foster adjustment, especially for individuals who may have deficits in their existing social network.

Finally, many relationship-based interventions in health utilize existing network members. These interventions usually attempt to mobilize a person's network via differing strategies. These usually including teaching the patient support-seeking skills and/or educating existing support members on the disease in question and how to best support the patient. It may also be important to teach the support provider additional coping skills as this can be a significant source of stress in some contexts (e.g., caregiver for an Alzheimer's disease patient). These interventions can be complex, given the long history of these relationships, but if harnessed carefully have shown to be beneficial for individuals.

A few additional comments about relationship-based interventions are important. First, it should be highlighted that such interventions in a health context are often cost effective, estimated in some cases to save the average patient thousands of dollars. A second issue is that most of the relationship-based interventions focus on individuals who are entering the health care system due to existing disease. Researchers such as Robert Kaplan have convincingly argued for the importance of primary prevention strategies that focus on healthy individuals. In the context of relationships and health, this is quite important because the major cause of morbidity and mortality are chronic diseases that develop slowly over time. Most of these early interventions have focused on social skills training in adolescents using a different set of outcomes (e.g., friendships, grade point average, etc.). Their potential influences on longer-term outcomes may be promising, as they may place individuals on more positive early relationship trajectories that then influence a wide array of outcomes.

Conclusion

There is a relatively large body of research linking relationships to physical health outcomes. As a result, recent research is examining the possible pathways responsible for such links. These studies are interdisciplinary in nature and helping to provide a more integrative picture of the complex links between social ties and health. This work holds great promise to not only complement

existing biomedical views, but also to highlight multiple potential entry points for intervention.

HEALTH BEHAVIORS, RELATIONSHIPS AND INTERPERSONAL SPREAD OF

Human beings are embedded in networks of other individuals from the time they are born, and these *social networks* have important consequences for all aspects of human experience. A thorough understanding of the relationships that constitute these networks is crucial to understanding the nature of any individual. This is true with respect to social and personality aspects of the individual and true of physical attributes, including the health of the individual. Many studies have now shown that social isolation puts people at increased risk of disease and early death. Conversely, social relationships have positive effects on health and longevity. People with larger social networks, for instance, are generally healthier and live longer. This entry discusses the role of relationships in the health of individuals across the life course and how health states spread within a social network.

Health Depends on Relationships

The powerful role of relationships in determining the health of the individual begins in infancy. During this earliest stage of our lives, we begin to form intense bonds with our primary caretakers (typically our parents). If the infant is not allowed to bond normally, its health may suffer serious adverse effects. This kind of disturbance of relationships early in life has been implicated as the causal factor in a syndrome known as “non-organic failure to thrive,” wherein the child fails to grow normally and remains small and sickly. This occurs despite a lack of any apparent organic cause. First observed by Anna Freud and Dorothy Burlingham in their work with children separated from their parents during World War II, phenomena such as these have made the aspect of human relationships known as *attachment* one of the most powerful explanatory tools in the understanding of healthy child development.

Just as with infant–caregiver attachment, attachments later in life have been implicated in determining the health and survival of the individual. A careful examination of how health is related to human relationships reveals that our health is

inextricably linked to those with whom we share our lives. For example, death in one spouse increases the risk of death in the other in what is known as the *widower effect*. Even hospitalization of one spouse may increase the risk of death of the other. But the widower effect may be a special case of a broader socio-medical phenomenon whereby health outcomes in one person are associated with health outcomes in those with whom that person is in a relationship. These outcomes could include not just death, but also illness, disability, and health behaviors.

Scientific attention to the role of social ties as determinants of health has increased dramatically in recent decades, and the effects of social relationships on health are ubiquitous and important. For example, greater “social support,” usually measured as more frequent contact with people with whom we have supportive relationships, is associated with lower incidence of disease and with better adjustment to specific illnesses, such as cancer and heart disease. Many of these positive effects of social support may be the result of the stress-reducing nature of receiving social support. The many stresses of everyday life contribute to illness, but the assistance and emotional support of close others tend to ameliorate that stress. In this way, our relational ties may make us resistant to the long-term effects of stress and illness on our bodies, leading to better health and longer life.

The Spread of Health States Within a Social Network

One important question that does not yet have a satisfactory answer is the extent to which interpersonal health effects may be found outside of spousal relationships—among siblings, friends, coworkers, or neighbors. For example, might not a heart attack or stroke in one individual trigger changes in the health or health behavior of others? Might eating or exercise patterns in one person induce similar patterns in others?

Some of these questions suggest that health states and behaviors may spread from person to person, in the manner of a fashion trend. There may be epidemics of health problems such as obesity, alcoholism, suicide, or depression that might spread in a peer-to-peer fashion. A striking

illustration of such an interpersonal spread of health states is provided in a study by Nicholas Christakis and James Fowler, who examined the spread of obesity in a group of individuals enrolled in a large medical study known as the *Framingham Heart Study*. For each member of this group of 5,124 individuals enrolled in 1971, whom they term “egos,” the researchers identified a diverse set of individuals (their “alters”) connected via various kinds of social ties (e.g., spouse, friend, sibling, neighbor), for a total social network size of 12,630 individuals. Changes in family relationships (because of birth, death, marriage, or divorce) and other relationships (because of residential moves or new jobs or friendships) were captured across seven survey periods between 1971 and 2003. At each of these seven points in time, many physical measures were also taken, including height and weight. Obesity was found to spread among individuals in a variety of different relationships. With respect to mutual friends, for example, one becoming obese increased the other’s risk of obesity nearly threefold. Similar interpersonal social network effects were seen for other phenomena, such as smoking behavior or depression.

Conclusions

In summary, health is a social phenomenon supported by an architecture of social relationships. Within our social networks, the health of one person affects the health of others, often in profound ways. Illness, health behaviors, or death in one person can contribute to similar outcomes in others in their social networks, through a non-biological spread of disease. In this way, human relationships form a framework in which health states arise and are maintained. Understanding precisely how social network ties affect human health is an important new area of research on health and health care policy.

HELPING BEHAVIORS IN RELATIONSHIPS

Helping behaviors are behaviors intended to benefit a relationship partner in response to an actual or perceived need; examples include the provision of social support, willingness to sacrifice, and accommodation. Helping behaviors are a type of *prosocial behavior*, which is a broader category of social behaviors intended to benefit others. Although there are many forms of prosocial behavior (e.g., sharing, cooperating, adhering to norms of honesty, fairness, and reciprocity), only a subset of these are enacted in response to the needs of others and are thus considered forms of helping. This entry describes different forms of helping behavior, examines the motivational underpinnings of helping, and identifies the personality and relationship factors that predict effective and ineffective helping in ongoing relationships.

What Is Helping?

Helping behavior can take many forms, but the type of help most often studied in ongoing relationships is *social support*. Social support serves two broad functions: (1) to help others cope with stressful life events and (2) to facilitate their goal strivings. The first type of social support—assisting others during times of adversity—has been labeled *safe haven* support. This type of support involves the provision of *instrumental aid* (e.g., material resources, task assistance, problem solving) or *emotional support* (e.g., physical affection, comfort,

understanding) that is intended to relieve another person's distress, assist that person in his or her coping efforts, and protect or promote his or her health and well-being. Research has shown that receiving social support during times of adversity helps individuals cope more effectively with stress and is associated with better health and psychological adjustment.

The second type of social support—assisting others in their goal pursuits—has been labeled *secure base* support. This type of support involves the provision of *instrumental aid* (e.g., material resources, information) or *emotional support* (e.g., encouragement, validation) that is intended to facilitate another person's goal-strivings, personal growth, and exploration. Research has shown that when people receive support for their goal strivings, they have higher self-esteem and self-efficacy, are more motivated to pursue personal goals, and more likely to make progress toward actually achieving these goals.

Two related lines of work examine other pathways through which partners help each other achieve their goals and celebrate their successes. First, research on the *Michelangelo phenomenon* shows that people are more likely to become the person they want to be (their ideal self) when a partner affirms and validates their ideal self and behaves in ways that help move them toward this ideal. Second, researchers have shown that partners play a critical role in helping each other capitalize on positive events. For example, when one person shares a success with another (a process called *capitalization*), the benefits of this success for that person's well-being are amplified if a relationship partner responds with active, enthusiastic support (e.g., by expressing pride and excitement or sharing the achievement with others). This research demonstrates that relationship partners play an important role in helping each other benefit from the good times, rather than just coping with the bad times.

Another form of helping behavior is *willingness to sacrifice*. Situations involving willingness to sacrifice arise when relationship partners have conflicting goals, needs, or preferences (through no necessary fault of either partner). Sacrifice occurs when one partner forgoes his or her own desires to allow the other partner to fulfill an important desire. Sacrifice is a form of helping behavior

because it involves one person's willingness to forgo self-interest to respond to the needs of a relationship partner.

Other forms of helping behavior include *accommodation* and *forgiveness*. Situations involving *accommodation* and *forgiveness* arise when one partner engages in a negative act (a transgression or betrayal), thereby imposing an emotional or material cost on the other partner. *Accommodation* occurs when the offended person refrains from responding negatively and instead responds in a constructive manner that defuses negativity and promotes the well-being of the other person (and the relationship). *Forgiveness* occurs when the offended person ceases to feel resentment or anger toward the transgressor or ceases to demand punishment or restitution. Accommodation and forgiveness are forms of helping because one person overcomes negative thoughts, feelings, and behaviors to benefit the partner or the relationship. Moreover, accommodation and forgiveness are often motivated by the desire to meet the emotional needs of a partner. For example, forgiveness is often motivated by a desire to reduce another person's suffering by relegating the betrayal to the past and relieving the offender of guilt or shame.

In summary, helping behavior can take many forms in ongoing relationships and can occur during good times and bad times. Common in all these forms of helping is an act of caring or goodwill by one person that is intended to meet the needs of another, thereby promoting that person's well-being.

Although helping is intended to benefit others, not all helping efforts will be successful, and even well-intended behavior can have unintended negative consequences. For example, helpers may offer support in a way that leads the recipient to feel incompetent, indebted, or like a burden. Thus, researchers have focused on the quality of the help people provide as well as on whether people help (or how much they help). Effective helping behavior is characterized by two key features: *sensitivity* and *responsiveness*. *Sensitivity* reflects the degree to which the helper's behavior is in synchrony with, and appropriately contingent upon, the needs of the recipient. *Responsiveness* reflects the degree to which the recipient feels understood, validated, and cared for. Thus, regardless of the type of help being provided, the benefits of that

help will depend on the degree to which it is sensitive and responsive to the recipient's needs.

Providing effective help is not always easy—it requires a variety of skills (e.g., perspective taking, emotion regulation), adequate resources (e.g., cognitive and emotional resources), and sufficient motivation. As such, helping is likely to be easier for some people than for others and in some relationships compared with others. The following sections examine the motivational, personality, and relationship factors that predict whether people help and whether their helping behavior is sensitive and responsive.

Motivations for Helping

Social and evolutionary theorists agree that caring for others is a universal human tendency—human beings have an innate propensity to engage in actions that benefit others, to feel compassion toward those who are suffering, and to protect and promote the welfare of others. Nevertheless, the motivation to provide help in specific situations (and the quality of help provided) will vary across situations, people, and relationships. Researchers distinguish between two different aspects of motivation: (1) one's overall degree of motivation to help (felt responsibility for responding to another's needs) and (2) the specific form of that motivation (altruistic versus egoistic).

In general, people will be more motivated to help others if they feel personally responsible for meeting the others' needs and have the skills and resources to do so. Felt responsibility can vary across relationships (e.g., people feel more responsible for meeting the needs of their children than of their friends), people (e.g., people differ in their chronic level of *communal orientation*), and situations (e.g., people feel more responsible for helping when they are the only person present during a situation of need).

Even if individuals are equally motivated to care for others in terms of felt responsibility, they may differ in the nature of that motivation. Helping behavior may be motivated by the desire to promote another's welfare (*altruistic motivation*) or the desire to gain benefits for the self (*egoistic motivation*). These motives may be dispositional, relationship-specific, or situation-specific. One

important situational factor is the degree to which the helper feels *empathic concern* (sympathy, compassion) versus *personal distress* (alarm, anxiety, guilt) in response to a person in need; empathic concern increases altruistic motivation, whereas personal distress increases egoistic motivation.

Distinguishing between altruistic and egoistic motives is important because these motives shape helping behavior. Helpers who are altruistically motivated tend to be more effective helpers—they are more attuned to their partner's signals, more willing to expend effort to respond appropriately to these signals, and more likely to provide help in a manner that expresses their benevolent motives. In contrast, helpers who are egoistically motivated tend to be focused on their own needs, which interferes with their ability to provide optimal help to others. Although altruistic motivation is associated with more effective helping than is egoistic motivation, both forms of motivation mobilize helping behavior and increase the likelihood that an individual will respond to the needs of others.

Individual Differences in Helping

Because effective helping requires adequate skills, resources, and motivation, people differ in their willingness and ability to help others in need. Research shows that individuals who have a *secure attachment style* (who are comfortable with closeness and confident that they are loved) are more likely to provide sensitive and responsive support to their relationship partners and more likely to help for altruistic versus egoistic reasons. In contrast, insecure individuals are less effective helpers. Those who are high in attachment *anxiety* (worried about being rejected or unloved) tend to have an over-involved, intrusive caregiving style that is out of synch with their partner's needs, and although they are altruistically motivated to help others, they are also egoistically motivated (e.g., they help others to be loved and needed). In contrast, those high in attachment *avoidance* (uncomfortable with closeness) tend to be neglectful and controlling in their caregiving style, and they tend to help others for largely egoistic reasons (e.g., to gain benefits for the self or to avoid sanctions for not helping).

Researchers have also identified broad personality dimensions that are linked to helping behavior.

Individuals who are high in *agreeableness* (pleasant, kind, concerned with cooperation and social harmony), dispositional *empathy* (a tendency to take the perspective of others and to feel compassion for those less fortunate), *prosocial personality orientation* (a tendency to be concerned for the welfare of others and to act in ways that demonstrate this concern), *communal orientation* (adherence to a norm of mutual, noncontingent responsiveness to needs), and *compassionate love* toward humanity (an attitude containing feelings, thoughts, and behavioral predispositions focused on caring for, supporting, and understanding others) are more likely to provide help to others in need (strangers as well as ongoing relationship partners).

Individual differences in chronic social motives have also been linked to various forms of helping behavior. For example, approach and avoidance motivations have been linked to different motives for sacrifice in intimate relationships. Individuals who are high in *approach motivation* (who focus on attaining social incentives such as closeness and affiliation) are more likely to sacrifice to attain positive outcomes for their partner and their relationship (e.g., to make their partner happy, to increase closeness). In contrast, those high in *avoidance motivation* (who focus on avoiding social threats such as rejection and conflict) are more likely to sacrifice to avoid negative outcomes (e.g., to avoid feeling guilty, to avoid upsetting their partner). Approach motives for sacrifice are associated with better psychological and relationship outcomes. In related work, individuals who give priority to pursuing *ego goals* (who seek to construct, maintain, protect, and enhance positive images of the self) are less likely to cultivate supportive friendships than are those who give priority to *compassionate goals* (who seek to support and promote the welfare of others).

Evidence also suggests that chronic differences in self-regulatory resources affect certain forms of helping behavior. For example, individuals who have *poor self-regulation skills* (who have difficulty controlling their impulses) are less likely to engage in accommodation behavior in their intimate relationships. Likewise, individuals who are *chronically self-focused* are less effective support providers, presumably because they have fewer cognitive and emotional resources for discerning

and attending to the needs of others as well as more egoistic motives for helping others.

Finally, researchers have examined sex differences in helping. Overall, there are few differences between men and women in their helping behavior or in their motivations for helping, but two reliable effects have emerged. First, men are less likely than are women to provide sensitive emotional support to same-sex friends. This difference appears to be due primarily to norms concerning the appropriateness of comforting behavior in male same-sex relationships, but evidence also indicates that men are less skilled than are women at providing emotional comfort. Second, men are more likely to provide instrumental aid to strangers in need (a situation in which women may feel less comfortable or safe intervening), but it is not yet clear whether this gender difference also occurs in close relationships.

Relationship Features That Promote Helping

Although personality factors play an important role in helping behavior, the strongest predictors of helping in ongoing relationships are features of the relationship itself. Many of these features increase helping by increasing felt responsibility for the welfare of relationship partners. Felt responsibility is greatest in relationships that are high in interdependence, commitment, emotional closeness, and trust, all of which foster communal norms that encourage mutual responsiveness to needs. For example, according to *Interdependence Theory*, when one person's life is deeply intertwined with a relationship partner, and when that person is committed to maintaining this relationship, they enact *transformations of motivation* in which the desire to pursue self-interest in a given situation is replaced or supplanted by the willingness to pursue outcomes that promote the welfare of the partner or the relationship. Research shows that relationship commitment increases a variety of pro-relationship behaviors including accommodation, forgiveness, and willingness to sacrifice.

Relationships also differ in the norms that govern the giving and receiving of benefits. *Exchange relationships* (such as relationships with business partners) involve a tit-for-tat norm in which benefits are given with the expectation of immediate

and comparable benefits in return. In contrast, *communal relationships* (such as relationships with family and friends) involve a norm of mutual responsiveness, in which benefits are given in response to needs as they arise with no expectation of benefits in return. Relationships also vary in their level of *communal strength*. Communal strength reflects the degree to which a person feels responsible for meeting the needs of a partner and is willing to incur costs to meet those needs. For example, parent-child relationships are high in communal strength; parents feel a great deal of responsibility for meeting their children's needs and are often willing to incur large costs to meet these needs. Overall, research shows that people are more likely to help others with whom they have a communal versus an exchange relationship and that helping behavior increases as the degree of communal strength increases (e.g., people are more likely to help a spouse than a friend, and more likely to help a friend than a neighbor.)

Relationships highest in communal strength tend to involve kin. This pattern is consistent with evolutionary perspectives on helping. According to Kin Selection Theory, prosocial behavior evolved because it increases inclusive fitness (the successful transmission of one's genes from all sources to the next generation); therefore, helping behavior should increase as the degree of genetic relatedness increases between the helper and the person in need. Consistent with this approach, research shows that people are more likely to help kin than to help nonkin; and even among kin relationships, degree of genetic relatedness predicts additional variance in helping behavior. Some theorists have suggested that feelings of emotional closeness or communal strength (which promote helping behavior) may be proximal psychological mechanisms that mediate the link between genetic relatedness and willingness to help.

In addition to increasing the motivation to respond to the needs of another, relationship features also affect whether individuals are altruistically or egoistically motivated to help others. For example, altruistic motives are greatest in relationships that are high in compassionate love and emotional intimacy, partly because these qualities foster empathic concern, which is a critical source of altruistic motivation. Altruistic motives are also strong in relationships that are high in trust and

felt-security (confidence in a partner's love and commitment), partly because these qualities reduce self-protective (egoistic) motives for helping (such as helping to earn a partner's love or helping to increase a partner's dependence on the relationship) that can interfere with other-oriented emotions and actions. Research shows that when individuals feel secure and confident in their partners' regard, they are more willing to sacrifice, more accommodating, and more willing to forgive transgressions; they are also more likely to provide sensitive and responsive support to relationship partners during stressful and nonstressful times.

HISPANIC/LATINO FAMILIES

The U.S. Census reports that since the turn of the 21st century Hispanics/Latinas(os) have become the largest racial/ethnic minority in the country. In 2003, Hispanics/Latinas(os) surpassed African Americans, who were then the largest racial and ethnic minority, reaching an unprecedented 13 percent of the U.S. racial/ethnic population. The labels *Hispanic* or *Latina(o)* are panethnic concepts frequently used to describe Latin-American and Caribbean immigrants and their children. These concepts are a convenient, albeit controversial, way to describe this rather diverse community. The label *Hispanic* was introduced by the U.S. Census and is used mostly in government, policy, and social science reports, whereas the label *Latina(o)* is a community-based term frequently presented as a political alternative to *Hispanic*. Surveys conducted in the Hispanic/Latino communities suggest that endorsement of these labels varies a great deal by nationality and that sometimes both terms are used interchangeably. Yet, surveys also reveal that the preference for most immigrants and their U.S.-born second and third generation is to be identified by nationality. The lack of a standardized terminology can be explained by the demographic diversity in the Latino community and the politics of ethnic labeling.

Indeed, Hispanics/Latinos are a community differentiated by nationality (Mexicans, Puerto Ricans, and Cubans are the three largest groups), race (there are White, Brown, and Black Hispanic/Latinos), social class, and gender or sexuality. Within each of these communities, age, education, and immigration status further differentiates individuals and families. Most social scientists agree

that each group in the Hispanic/Latino community has had a unique history of migration, settlement, and incorporation into U.S. society. Mexicans, for example, are by far the largest group of recent arrivals, but with a long presence in U.S. history. Their entry goes back to 1848 when 40 percent of Mexico's territory became part of the United States as stipulated by the Treaty of Guadalupe de Hidalgo. As a consequence, the largest and oldest Mexican communities can be found in the Southwest and on the West Coast. Puerto Ricans do not cross a national border because they are U.S. citizens by birth, but their migration to the United States goes back to 1898 when the island became a U.S. territory (colony). Several generations of Puerto Ricans have called New York City home, making it the oldest and largest Puerto Rican community on the mainland. Significant settlements can also be found in Chicago, Philadelphia, Boston, and Orlando. Groups such as Cubans, Dominicans, and Guatemalans represent unique and complex chapters in the most recent Hispanic/Latino immigration waves. But, regardless of the differences that exist between and within these communities, the family is (and has been) an important institution in the Latino community across the hemisphere, the topic this entry seeks to address.

Unfortunately, descriptions of Latino family life and family relations have been distorted by both positive and negative stereotypes. *Familismo* is a concept frequently used to describe large extended family relations and the notion that Latinos place a high value on family, marriage, and tradition. Other cultural stereotypes that have become accepted scholarly concepts are the notions of *machismo* and *marianismo*. *Machismo* is a stereotypical construction used by social scientists to describe Latino men across social classes and locations as physically strong, tough, virile "machos" who demand respect and control of the family. Marianismo, on the other hand, is used to describe women as passive, docile, self-sacrificing, and submissive mothers and daughters. These concepts have been deployed by social policy analysts and social scientists to make blanket assessments and evaluations of Latino families as steeped in tradition and unable to change because of rigid gender roles. For example, machismo has become a convenient explanation for a range of social problems facing Latino families such as inability to adapt to

U.S. culture, poverty, and domestic violence. Similarly, the image of the docile mother, wife, and daughter attached to tradition has become a prevalent stereotype of Latinas and a convenient trope for explaining the perceived higher fertility rates and the lack of social change in Latino families. These stereotypes rest in the pervasive distortion of Latin America and the Caribbean as societies steeped in tradition with a rigid gender division of labor and the United States as a "modern," more flexible society where gender roles can be negotiated. Researchers seem committed to the *machismo/marianismo* dichotomy even when the historical conditions across the hemisphere suggest otherwise. The task for future researchers interested in studying Latino families is to learn to recognize how family gender relations are shaped by material and historical conditions. In other words, gender dynamics in Latino families have been forged historically and have varied by race and social class.

Historical Overview

We know that the institution of the family played an important role in the historical settlement of the Americas. Many of the values associated with Hispanic/Latino families today—large extended families, honor, respect, religiosity, among cultural values—are rooted in the colonization of the Americas by Spain and Portugal. Historians have documented how legal marriage and the social rituals of marriage were important markers of social status and the foundation of the successful transplantation of Spanish and Portuguese cultures to the Americas. Latin America and the Caribbean stand today as visual and tangible representations of the power of cultural transformation (some may say collision) when multiple cultures come into contact. Yet, we face a formidable task here because historical records have tended to privilege elites by preserving their history and neglecting how marginalized groups, in this case African and indigenous peoples, contributed to the cultural (re)construction of families in the Americas. An analysis and description of family life and family relations in the Hispanic/Latino communities requires recognition of how race, social class, and gender hierarchies were (still are) maintained and reconstructed through both the

material conditions and discursive practices of families across the hemisphere.

In colonial Latin America, endogamy characterized marriage for elite families, but that did not prevent Spanish and Portuguese men from establishing extramarital affairs with Indian and African women, defying the strict rules about procreation and sex ordered by the Catholic Church. Today, many Latinas/os continue to organize family life according to Roman Catholic religious ideologies. For example, premarital sex and birth control are for the most part prohibited. Historically, the state and church gave men patriarchal control and power over women and children in the context of family life. In Latin America and the Caribbean, that did not mean that women were passive and dependent. Elite colonial women, for example, helped run their large-estate households (*haciendas*) and in the absence of their husbands took control of family business. One characteristic of marriage among the elite was large age differences between older husbands and young wives, resulting in higher rates of widowhood among elite women. In some cases, women remarried, but widows in Latin America accrued a great deal of social status by virtue of their inherited wealth. Marriage was a family affair, and because most people among the elite married each other, it meant the consolidation of wealth and property. Marriage also guaranteed the successful transmission of wealth and power to the next generation of landed elites.

Marriage for poor and working-class Indian, African, and *mestizo* (mixed race) women and men had different meanings. Most Indian, African, and mestizos were frequently found in consensual unions and what historians call *concubinage*, semi-permanent relations with a married man. The patriarchal bargain for working women was that since historically men's wages have been higher, a consensual relation allowed women to exchange both sex and domestic work for a portion of men's earnings and emotional support. The working poor needed each other to survive, and as a consequence, this helped in the formation of social class solidarity. For families, social class solidarity allowed working-class men and women to face the constant intrusion of elites on family life. Consensual unions afforded both men and women some protection and economic stability. Today, consensual unions continue to characterize Latino/a

families across the hemisphere, and social class solidarity has characterized social protests and revolutionary movements in Latin America and the Caribbean.

Other social problems that shaped (and continue to shape) family life across the hemisphere were high rates of illegitimate children and the presence of female-headed households. The need for survival frequently brought women together in family-like arrangements where rent, work, and childcare were shared. Like today, female-headed households were among the poorest and most marginalized groups in Latin American and the Caribbean. Children in these family arrangements were also vulnerable to poverty, malnutrition, and other social problems. The historical continuities shaping Latina/o family life are striking, but one must also recognize how changing social and economic conditions have shaped the formation of other family patterns and social problems.

The stereotype of Latinas as home-bound, passive, and submissive has been challenged by the realities of family life and women's work experiences across the hemisphere. Latinas have supported their families through both work for wages in the formal and informal economy and the work done on behalf of their families such as reproducing the next generation of workers and caring for family members. Feminist scholars have captured this duality as the productive-reproductive dimensions of family life. Industrial and postindustrial capitalism (also known as *globalization*) has consolidated the entrance of women into wage labor across the hemisphere. Women in Mexico, Puerto Rico, Chile, Cuba, and Brazil have entered the labor market in great numbers both to supplement the wages of their husbands and to provide for their families given the high rates of single-headed families. The feminist movement in Latin America and the Caribbean has also raised expectations about the social role of women in Latina/o societies. The consolidation of women's role as providers has introduced many problems for families across the social spectrum partly because this change was not accompanied by any significant changes in men's roles and social policies to aid families with childcare and other social services. Instead, like women in the United States, Latin-American and Caribbean women face the double burden of working for wages and the second shift at home. Even in Cuba,

where the state has offered women a range of social benefits such as government-subsidized childcare and paid maternity leave, Cuban women continue to bear the burden of caring for their immediate and extended families.

Family, Gender, and Migration

Across social classes, internal and international migration has been a strategy used by both women and men to address a range of family needs, whether economic, educational, health, or gender related. The tendency to see migration as simply an economic act has been challenged by decades of research on the gendered dimensions of migration and settlement conducted among Hispanic/Latino communities. Feminist researchers in both Latin America and the United States have documented the multiplicity of ways family relations have been altered by migration practices and how migration strategies are forged to address a multiplicity of family needs and problems, including gender oppression. Gender oppression has emerged as an important factor shaping the contemporary migration of Latin-American and Caribbean women to the United States and other parts of the world.

Research with Mexican immigrants in California has documented how the spousal separation endured by men and women because of restrictive immigration laws has altered women's and men's roles in the family. It has pushed married women left behind to work outside the home and forced men in the United States to take on household tasks such as preparation of food, laundry, and cleaning. Researchers have also documented how some working-class immigrant men develop second families in the U.S. communities, thereby reproducing the historical tendency for men to have extramarital affairs and children outside marriage. One of the most intriguing areas of research is the work currently being conducted to analyze the changes in the social reconstruction of masculinity among Latino immigrant men.

Researchers have also documented how women use migration as a way to assert their gender identities and reunite families. Research with Central-American immigrants has documented how single mothers forge migration practices to provide for their families by becoming domestic workers and

surrogate mothers for privileged U.S. families. These transnational mothers, as they are frequently called, support themselves and their families across time and space. They have forged a gendered identity of themselves as working mothers that accounts for long absences and that splits social reproductive work between the United States and their countries of origin. Many of these women have entered the United States without documentation, thereby adding an additional source of stress to their family lives. In a post-September 11, 2001, world of border enforcement and deportations as a way to enforce immigration laws, Latina working mothers have become targets of government persecution. In 2007, the case of Elvira Arellano, an immigrant woman from Mexico who had entered the United States without documentation, called attention to the plight of working immigrant mothers. She had worked for many years in the city of Chicago, eluding immigration authorities. She had also given birth to a son, Saul, who was an American citizen by birth. She fought deportation by seeking asylum in a church in the city of Chicago and pleaded with government officials to allow her to stay and continue to raise her son, who by now was going to school. When she left the church to attend an immigrant rally in Los Angeles, she was arrested and deported to Mexico.

Research with Puerto Rican migrants in Chicago suggests working-class men tried to maintain a more traditional family life and division of labor by taking on two jobs, thus allowing women to stay home and care for children, a task many perceived as critically important to the cultural survival of the family given the dangers of living in large urban centers. Yet, economic needs frequently pushed working-class women to work outside the home and support their families. In Chicago, as in Puerto Rico, working-class women were responsible for both the reproductive work that supported their families and working outside the home. Educated and middle-class immigrant women in Chicago reported a more flexible gender division of labor, partly because they had already negotiated work and family arrangements in Puerto Rico. Indeed, researchers agree that working outside the home gives women a measure of freedom and empowerment, but such "liberation" can be seriously eroded by racial and social class hierarchies

that compound the difficulties faced by immigrants living in the postindustrial economies of destination societies.

For other immigrant groups, particularly Central-American immigrants, women have become primary breadwinners for their families because of labor market conditions in many U.S. cities, namely decline of manufacturing and need for service and unskilled work. The inability of some Central-American men to provide for their families leads to spousal separations, divorce, and domestic violence in the family. By contrast, indigenous Guatemalan immigrants come from more egalitarian family arrangements and thus perceive women's increased ability to procure jobs as an opportunity that benefits all in the family.

Children of Latino immigrants, many of whom have been born and raised in the United States, are also developing their own family dynamics and practices. Research conducted among second- and third-generation Latinos in California, Illinois, and New York suggests that, for example, parents are more likely to be educated and employed. Women have lower fertility rates when compared with their mothers, but researchers caution that some nationality variations are worth noting. Among Latinas, Cubans have lower fertility rates when compared with Mexican-origin women and U.S.-born Mexican women. Second- and third-generation Latinos are also more likely to live in nuclear families, in contrast to their immigrant parents. Second- and third-generation Latinos are also more likely to marry outside their group—in some cases, that means other Latino groups (Mexicans and Puerto Ricans) and across groups (Whites and Blacks). U.S.-born Latinos report a more egalitarian gender division of labor, but that is also shaped by social class differences.

In closing, the diversity that exist in the Latina/o experience makes generalizations difficult though key social processes such as globalization and migration have shaped family dynamics across the hemisphere.

HOLIDAYS AND RELATIONSHIPS

Holiday initially was derived from the longer term *holy day*, involving a relationship with a spiritual deity. The word now encompasses a range of secular, national, and religious celebrations inherently linked with personal relationships. Indeed, in the modern United States, spending a holiday alone is considered by many to be the pinnacle of isolation. Different holidays include different rituals, social partners, and types of relationships. Holidays provide a forum for explicating the nature of relationships. Celebrating a given holiday together can define the degree of intimacy between social partners. Some holidays expand social networks, whereas other holidays demarcate boundaries around close ties. Holidays also provide a sense of continuity and rhythm that allow for shared reminiscence and common bonds, particularly within families. Shifts in patterns of celebration can indicate transitions within those relationships. Finally, because holidays make explicit those aspects of relationships that may typically go unstated, holidays can generate intense emotions. This entry explains how holidays provide definition and continuity in relationships and how individuals may react to those celebrations.

The range of celebrations and festivities mimics the range of personal relationships in the modern world. Holidays help define ties between people, with some holidays encompassing a wide array of social ties, and other holidays limited to the closest ties. For example, a Christmas card list may include intimate, acquaintance, past, and business ties. Likewise, people celebrate national festivals such as the U.S. 4th of July with a conglomerate of friends, friends-of-friends, neighbors, and picnic lovers. By contrast, Thanksgiving brings together extended family, whereas an anniversary is a personal holiday, circumscribed to the two people in that relationship. Some holidays, such as birthdays, are semiprivate. Individuals presume a degree of intimacy with people who send a birthday card or gift.

Personalizing holidays can also establish intimate relationships or define cycles within those relationships. For example, romantic couples may create holidays to commemorate important moments in the relationship, such as eating

annually at a certain restaurant. During the development of the romantic tie, negotiations over how to spend holidays typically celebrated with family (e.g., Thanksgiving) may formalize the relationship. Childrearing also often entails the institution of new holidays or personalizing existing holidays to reinforce the family as a unit. Families may engage in a formal rite of definition such as the family reunion, or they may generate idiosyncratic holidays such as the annual camping trip, an ice cream party on the first day of school, or even the Pie Day one family dreamed up.

Holidays also generate discontinuity from the normal routines of daily life in favor of rituals or celebrations. Holidays recur on a cyclical basis, usually each year. In the modern world, we tend to conceptualize time as linear, viewing individuals and relationships as developing and changing. Holidays can facilitate this progression and further strengthen ties. For example, birthdays indicate the growth of a child and shifts in relationships with that child, whereas anniversaries mark the duration of a marriage. Yet, holidays also introduce cycles within relationships and generate feelings of continuity. The annual nature of the rituals is reassuring and may ground the relationship.

The repeated nature of holiday celebrations also allows for connection via shared memories and experiences. Reminiscence with social partners regarding past holidays allows people to feel connected in the moment, as well as over time. For example, holiday rituals generated in childhood often transcend to the next generation, with cookie recipes passed down on stained paper. Likewise, people derive connections from maintaining relationships that arise only at a holiday, including distant partners who exchange Christmas cards or an in-law's hard-of-hearing grandmother who attends Thanksgiving dinner. These individuals are not a part of everyday social networks, but provide a sense of stability over time.

Holidays are marked by symbols and rituals that provide a forum to render implicit features of relationships explicit. People may communicate sentiments they do not typically state. The greeting card industry has capitalized on this aspect of holidays, even marketing new holidays (e.g., Grandparent's Day) for expressing feelings of attachment. As such, items associated with the

holiday can take on deep meaning in the context of relationships, such as the ornament a grandchild made in kindergarten or the punch bowl a couple always uses on New Year's Eve.

Holidays also set up platforms for social exchange, both with regard to artifacts (e.g., holiday cards) and in terms of who is the host of the celebration. Social partners may celebrate a certain holiday at one person's house, and the next holiday at the other person's. Alternately, one person may always host a particular holiday, symbolizing that person's role as the leader in a set of relationships.

Because holidays are deeply embedded with formality and ritual, individuals may fall into traditional relationship roles they do not assume in daily life. For example, couples that try to be equitable in their housework may find gender roles intensify around holidays with the women in the kitchen baking and cleaning up while the men watch football games. Grandmother may be the "kinkeeper" who organizes all of her progeny to attend an event at her house.

Holidays also may mark critical transitions within relationships. When a son brings his new girlfriend to the annual Memorial Day cookout, family members note this event as an indicator of the seriousness of that romantic tie (for that matter, it may signify the same to the son and his girlfriend). In another setting, the entire family may be aware that grandfather's health is failing, but it is the evening when he allows someone else to lead the Passover Seder that formalizes his relinquishing the role of patriarch and the evolution of new familial roles.

Although the premise of a holiday implies celebration, holidays also may involve challenges. Some holidays include arduous rituals such as the fasting periods of Jewish Yom Kippur or Muslim Ramadan that place shared privation on adults within these communities. As such, these holidays may provide a forum for people to solidify relationships as they support one another through the fast and celebrate the end in a collective meal.

Even holidays intended to be festive may evoke negative emotions. The cyclical nature of holidays allows family systems to fall into established behaviors that may be maladaptive for some of the members. Popular media often portray the dread adults feel about returning to their parents' home to celebrate Thanksgiving with extended family.

Holidays can bring together large family groups with ingroup dynamics from the past that evoke individual distress or subgroup dynamics, such as the yearly family argument.

HOMELESSNESS AND RELATIONSHIPS

People who are homeless sometimes lack positive relationships with others who might have provided them a social safety net to prevent homelessness. Indeed, some scholars consider social isolation or "disaffiliation" a defining characteristic of homelessness. This entry follows the more usual practice of defining homelessness in terms of residential status. Researchers in the United States tend to focus on *literal homelessness* or sleeping in shelters, public places, or other locations (such as cars or abandoned buildings) not intended for habitation. European researchers often include living with others because one has no place else to go, or having tenuous ties to housing, conditions

that are also labeled “precariously housed.” U.S. definitions of adolescent homelessness also tend to adopt a broader framework, including staying with strangers because one cannot or does not want to go home. This entry examines bidirectional associations between homelessness and both lack of positive relationships with others and presence of negative or disruptive relationships.

Homelessness and Lack of Positive Relationships

Researchers in this area most often study people in the midst of a homeless episode, rather than those on the verge of homelessness or the much larger group of people who have reestablished themselves in housing. Many, but not all, such studies find that some currently homeless people have impoverished social relationships with friends or relatives who might be able to help them. In some cases, the loss of social relationships clearly predates homelessness. Homeless adults, whether homeless by themselves or with their families, are more likely than are other poor people to have been separated from their families of origin, been placed in foster care, or had a parent die when they were children. The loss of a relationship, such as divorce, sometimes precipitates homelessness, and rates of single parenthood are high among homeless families in the United States, as they are among poor families generally. Perhaps a quarter of single homeless adults have experienced mental disorders such as schizophrenia that often involve social isolation, but such disorders are rare among homeless families.

In other cases, people draw on friends and relatives for housing and other supports before becoming homeless, but eventually wear out their welcomes with members of their social networks. A study in Chicago found that homeless adults had lacked steady jobs for an average of 2 years longer than they had been homeless, and a study in New York City found that over three quarters of homeless families stayed with friends and relatives before turning to public shelters. At the time of their initial shelter request, homeless families reported more recent contacts with relatives and friends than did a comparison group of poor families who remained housed. In these cases, it

may not be lack of social ties so much as the inability of social network members to supply material resources that leads to homelessness.

Even where lack of social relationships predates homelessness, the critical missing ingredient may be economic resources rather than emotional support. Rates of homelessness are much lower in Europe, and homelessness among families is rare even where rates of single parenthood are comparable to or higher than in the United States, probably because of more generous income support policies. In a longitudinal study in New York City, housing subsidies created the same levels of housing stability for previously homeless families as for families in the welfare caseload generally. After accounting for housing subsidies, no psychosocial characteristics or characteristics of relationships, past or present, predicted housing stability.

An episode of homelessness can also disrupt social relationships when it leads to residential mobility, loss of phone service, or relocation to new neighborhoods. Shelters sometimes require families to break up, with men and older boys segregated from women and younger children, and homeless mothers often become separated from their children, who may stay with relatives or go into foster care. Embarrassment by people becoming homeless or anger that friends and relatives did not do enough to help, along with guilt by network members, can lead to tensions. Nevertheless, most people maintain some contact with friends and relatives while homeless, and many intersperse stays on a friend’s couch with episodes of literal homelessness.

Homelessness and Negative Relationships

The presence of negative social relationships may be more important to homelessness than is lack of positive relationships. Friction with family is often marked for homeless adolescents, who are sometimes dubbed “runaways” or “throwaways.” Adolescents most often cite family conflict as their reason for becoming homeless and report high rates of neglect and both physical and sexual abuse. Adolescents who become homeless, like their adult counterparts, have frequently been in foster care.

Homeless adults, especially but not exclusively women, also report high rates of physical or sexual

abuse and domestic violence. Studies that use brief, global measures find higher rates of domestic violence among women in homeless families than in comparable poor families. However, studies that use detailed checklists of violent behaviors find high rates of violence in both homeless and housed groups and few differences between them. Whatever the relative levels, it is clear that homeless women experience high levels of interpersonal trauma.

In sum, research suggests that the association between homelessness and social relationships is bidirectional. Lack of positive relationships and presence of negative relationships can contribute to homelessness in the absence of other sources of support, and homelessness, in turn, can disrupt people's social ties to others.

HONEYMOON

Honeymoon refers to a social custom or ritual linked to the transition to marriage that follows the wedding and typically involves a distancing of the newlywed couple from their social network and exemption from nonmarital responsibilities. Although popularly thought to be a uniform custom practiced throughout the ages, the term itself is more recent and the practices defining the

experience are far from uniform, although unique to modern societies. This entry discusses the historical development of the honeymoon and the functions of honeymoons.

The term first appeared in Thomas Blount's *Glossographia* in 1656, in which the definition makes no allusion to any ritual or custom but instead is used to identify a stage in early marriage where love is at first intense and sweet (like honey) but then diminishes like the waning of the moon. The word likely originated from a Northern European tradition where the newlywed couple drank honey mead for the first month of their marriage (the passing of one full moon). There are, however, earlier precedents for certain aspects of the honeymoon ritual. The earliest can be found in the Hebrew Bible book Deuteronomy, where husbands are exempted from military and economic responsibilities for the first year of marriage. Another precursor may have been the Northern European tradition of abducting one's wife from a neighboring village and remaining in hiding for a period when her family would have stopped looking for her (about one month). Although these traditions share some common elements with contemporary honeymoons (exemption from nonmarital responsibilities and distancing from community), neither approaches the sophisticated customs, meanings, or functions of today's honeymoons.

Historical Development of the Honeymoon

Historical evidence suggests that the “tradition” of honeymooning began in the late 19th century and was mostly developed into a cultural practice during the middle and late 20th century. Although there is evidence of couples practicing a “wedding night” tradition before this time, this amounted to little more than an opportunity to consummate the marriage and, as John Gillis points out in his history of marriage, was often a night interrupted by the high jinx of friends, family, and townspeople. Perhaps the closest precursor to the honeymoon was the “bridal tour” taken exclusively by the wealthy as this tradition involved temporary exemption from nonmarital responsibilities and a trip to a foreign location. Often, however, this trip was made to visit relatives and establish the couple

in a network of wealth—not a purpose associated with the honeymoon of today.

Based on a review of popular press writings on the honeymoon, Kris and Richard Bulcroft and Linda Smeins identified three distinct cultural story lines (or narratives) in the development of the honeymoon as practiced today. These narratives tell us only about cultural meanings attached to the honeymoon. In actuality, there is little evidence to suggest that honeymoons were practiced widely as recently as 1900. The custom has grown in popularity since, however, with most couples today taking a honeymoon and many preferring a lengthy experience (a week or more) in a distant, and usually tropical, location. These changes in practice reflect the changing narratives.

Before 1930, the honeymoon narrative involved short trips after the wedding where the couple immersed themselves in a local natural setting (e.g., canoeing down a river, staying at a self-care cabin) where they played out traditional marital roles involving protection and provision by the husband and domesticity and emotional support by the wife.

Between 1930 and 1960, this narrative gradually gave way to a second one infused with high levels of anxiety related to a new emerging model of marriage premised on the importance of psychological and emotional fulfillment in marriage rather than the enactment of instrumental roles. This new narrative stressed the importance of the honeymoon as a transitional event where the couple was expected to engage in intimate disclosures and develop a sense of mutual fulfillment. To help relieve this anxiety, many of the articles in this period incorporated the advice of relationship “experts” (physicians, therapists, social workers, ministers).

The setting for honeymoon stories during this time remained much the same, although advances in transportation made longer trips possible and the emergence of the “honeymoon resort” replaced more rustic accommodations. These resorts were critical to the custom because they provided for all the instrumental needs of the couple, freeing them to engage in the deep emotional and psychological work now required in modern marriages. With the growing emotional significance of the honeymoon, it also became an event of greater significance for brides than for grooms.

Over time (beginning in the 1960s through today), the importance of honeymoon resorts increased but their character and function for the couple began to change. A dominant theme of this last narrative involves high levels of planning and orchestration of an event that is infused with symbols of romance, takes place in a natural but now exotic (foreign and usually tropical) environment, and includes a myriad of fun activities to ensure that the event is highly rewarding.

Purpose or Functions of the Honeymoon

Early sociological writing on the honeymoon proposed that the honeymoon was an important “stage” in the development of marriage. Rhona and Robert Rapoport argued that the honeymoon was a “critical role transition” where the future of a relationship depended on the ability to complete two sets of “developmental tasks.” Two individual tasks to be accomplished were (1) developing sexual competence and (2) developing a facility for living with someone else. Two couple tasks were (1) developing a mutually satisfying sexual relationship and (2) engaging in a mutually satisfying shared experience that could help sustain their interest in the relationship later in marriage. Although these are four important factors in the development of relationships, the importance of honeymoons as a critical custom to help couples achieve these goals is more dubious, especially in a time when cohabitation and premarital sexuality are more the norm. If these were the reasons behind honeymoons, then the custom should be less widely practiced today instead of being more popular than ever before. These reasons also fail to explain why couples have become increasingly drawn to more elaborate, planned, and exotic honeymoon settings.

Reflecting on changes in relationships in modern society and in the honeymoon narrative suggests an alternative reason for taking honeymoons today. Perhaps this custom plays a part in helping couples confirm that they have made the best choice of partner by having a meticulously planned and “perfect” experience; obtain a sense of authenticity in their relationship by going to an exotic (nonmodern) tropical locale that provides heightened sensory experiences; and develop a couple

identity in an increasingly unconnected social world by going to a place imbued with meaning of class privilege and wealth, where they will be singled out as a newly married couple and where they can record their couple experiences for later presentation to others. Alternatively, or in conjunction with these reasons, participation in the honeymoon today may be fueled by economic interests present in a highly developed capitalistic society. Honeymoons are big business today. Whether the economic value of the custom drives its popularity, the personal and couple needs that do so, or a combination of both, there is little likelihood that this custom will become less important in the foreseeable future.

HOOKING UP, HOOKUPS

Casual sexual interaction among adolescents and young adults, especially college students, has been an important topic of study in the last three decades. *Hooking up* is a contemporary form of casual sexual relating popular among youth. *Hookups* are brief sexual encounters between individuals who are not-at-all, barely, or somewhat acquainted and with whom there is no

expectation of further relating. In keeping with the popular definition of casual sex, neither commitment nor emotion is expected in hookups. Hookups involving partners who know each other and may even be friends are referred to as “friends with benefits.”

Hookups involve a variety of sexual behaviors, including but not limited to sexual intercourse. More than half of older adolescents and young adults have hookup experience; some estimates are as high as 80 percent. Some evidence suggests that about half of individuals who hook up tend to engage in vaginal sexual intercourse as part of the interaction. Kissing, petting, and oral sex are also common in hookups.

Researchers and practitioners have viewed forms of casual sex as physically risky behavior, primarily increasing the hazard of contracting sexually transmitted diseases. Thus, a primary goal of research on casual sex, including hookups, has been to determine who is most likely to hook up and under what circumstances to develop prevention programs to effectively reduce the physical risks associated with these risky casual sexual behaviors. For example, researchers have examined personality and social factors common among youths who hook up. Individuals who have a preference for risk taking are more likely to hook up, as are individuals who have permissive sexual attitudes.

Individuals who begin to use alcohol at an early age, and especially those who tend to binge drink, are more likely to hook up. Alcohol use is also common before and during hookups, particularly those involving partners who do not know each other. Such risk takers, especially under the influence of alcohol, are also more likely to engage in sexual intercourse and are less likely to use condoms or other contraceptives during the hookup.

Youths are more likely to hook up in some situations than in others. Research on hooking up has focused primarily on college students. Only a few studies have studied noncollege-attending late adolescents and young adults; hooking up appears to be more frequent among youths in colleges and universities than among youths not attending college. Research on the transition from high school to college has revealed an increase in casual sexual behavior upon entering college. Researchers have also studied youths on vacation, especially during spring break, the famed college holiday. The likelihood of

engaging in hookups during spring break is quite high, as is other risk-taking behavior, such as lack of condom and other contraception use and bingeing on alcohol.

Youths' perceptions of social norms, or how common hooking up is in a particular situation, influences their likelihood of hooking up. Moreover, youths practice "pluralistic ignorance" wherein their perception of how comfortable or enjoyable their peers find hookups is greater than their own experience. This motivates youths to engage in hookups, partly because their skewed perceptions of their peers' experiences lead them to anticipate a positive experience and because they seek social acceptance and conformity with what they perceive as the norm. For some youths, hookups are seen as a route to social acceptance and status.

More recent research has further explored the subjective experience of hookups, including what motivates youths to hook up, and the unexpected emotional risks associated with hooking up. Motivations for both men and women include sexual desire and interest in sexual exploration and experimentation, as well as the possible outcome of positive social or interpersonal consequences such as popularity or romantic commitment. Some researchers have found that women are more likely than men to engage in casual sexual intercourse to increase their chances of starting a long-term relationship with their partners, whereas men are more likely than women to engage in casual sex to show their sexual prowess and enhance their social status.

Yet, research has also shown that hookup experiences are rarely simple and often result in complicated emotions. Most youths experience mixed positive and negative emotions during and after hookups. Women are more likely to feel certain negative emotions after hookups than men. Some hookups result in unwanted sexual interaction and can include sexual aggression and violence.

Young men and women have become more similar in sexual behavior patterns during the past two decades. However, it appears that youths' attitudes about sex, particularly the sexual double standard, are not changing as quickly. The sexual double standard is the Western cultural mandate that men are encouraged and rewarded for seeking opportunities to initiate and engage in sexual activity with a number of women, but women are

encouraged and rewarded for abstaining from sexual activity and controlling men's access to sexual activity. As a result, men experience validation for their sexuality whereas women experience chastisement for their sexuality. Such external responses are frequently internalized such that men feel pride in their sexuality and women feel shame and guilt.

The sexual double standard continues to play a role in some young adults' attitudes toward hooking up and especially in self-evaluations of their own sexual experiences. Women are more likely than are men to report feeling bad or used after their last hookup experience, and they are more likely to feel shame and regret for *their* (versus their partner's) behavior. Evolutionary psychology explains sex differences in emotional reactions to sexual experiences consistent with findings on the sexual double standard. This theory posits that women's negative affect following casual sex (i.e., "low-investment copulation") is adaptive—a warning that steers women away from low-investing men. In contrast, cognitive and social constructionist theories explain how cultural gender attributes may influence emotionality in casual sexual experiences. Cognitive theorists assert that emotional responses are labeled according to cultural *feeling rules* that are learned through socialization. Social constructionists view emotions as expected parts of social *scripts*, also learned through socialization. With traditional gender socialization comes sensitivity to expectations and "interpretational frameworks"—such as the sexual double standard—guiding specific emotional responses in sexual interactions.

In summary, hooking up is a significant feature of contemporary Western youth culture. Hookups are also complex interpersonal experiences that often surprise youths with their emotional intensity and complications. Just beginning to be explored by researchers and practitioners is the role of hookups in youths' development of important relationship skills. Hookups infrequently lead to the formation of a committed relationship, and when they do, the relationship tends to be short-lived. Also of interest is how hookup experiences and associated emotional ramifications affect later efforts to establish a stable love relationship.

HORMONES RELATED TO RELATIONSHIPS

Hormones are the chemical messengers of the body and are linked to romantic love, sexual arousal, social attachment between parents and their children, aggression, and many other aspects of human relationships. To understand how hormones play a role in relationships, it is first necessary to understand what hormones are and how they operate in the body. This entry explores what is known about the association between hormones and relationships, specifically social attachment, romantic relationships, and sexual behaviors.

What Are Hormones?

The word *hormone* comes from the Greek for “to arouse,” which is the primary function of these chemical messengers. The nervous system controls the release of the hormones. Most hormones travel through the circulatory system to stimulate target cells; however, some of these chemical messengers are released by nerve cells into the junction between two nerve cells (the synapse) or transported by the cerebrospinal fluid. Hormones

are also called neuroregulators because they stimulate or inhibit functioning in the nervous system. The steroid hormones are produced in the testes (androgens including testosterone) and ovaries (estrogens and progestins). Two of the hormones most associated with human relationships, oxytocin and vasopressin, are considered neurohormones or neuropeptides because they are manufactured in the hypothalamus area of the brain and then stored for subsequent release from the nerve terminals in the posterior pituitary gland. The hypothalamus is a part of the brain involved with the regulations of functions such as emotional behavior, arousal (including sexual arousal), biological rhythms, and homeostasis of the systems in the body.

Social Attachment and Love

Social attachment is thought to be at the heart of emotional bonds formed between people. This can be the bond between parents and their children, couples in love, and other forms of social bonds. The first of these bonds to be formed is the attachment between a caregiver and an infant. This attachment provides a secure foundation for the infant’s development, providing protection, nourishment, and socializing interactions. Research indicates that secure attachment between the child and caregiver is important to healthy child development.

Caregiver–Infant Social Attachment

Mothers experience a series of heightened hormonal processes before and during the birth of their children, including stress hormones from the adrenal glands and the release of oxytocin and vasopressin. Oxytocin is integral to the muscular contractions necessary for labor and delivery as well as to the production of milk by the breast tissues. Suckling by infants also increases oxytocin production. In both women and men, oxytocin and vasopressin appear to dampen stress by regulating the neuroendocrine components of the body that control stress-related hormones and enhancing the function of the parasympathetic nervous system that physiologically soothes the body (e.g., slow heart rate, lower blood pressure). Neural receptors for oxytocin are highly concentrated in

the parts of the brain associated with parenting behavior, emotional bonding between people, sexual behavior, and the capacity to form social attachments. Oxytocin and vasopressin are essential to a series of critical attachment behaviors in both women and men, including social recognition memory (learning the identity of the infant or adult partner), recognition of social and emotional facial cues (critical to successful nurturance), and trust (critical to the security of the relationship). Higher levels of oxytocin during and after pregnancy are associated with better maternal bonding behaviors in women including affectionate touch and warm thoughts about the baby. Experimental studies with men have found that the inhalation of oxytocin is linked to increased trust and enhanced ability to read facial emotional cues. These neuropeptides play a role in social attachment, and the lack of social attachment may affect the development of offspring. For example, orphans raised in aberrantly low caregiving and neglectful environments exhibited lower than normal levels of oxytocin in response to their adoptive mothers' physical contact. These orphans also exhibited abnormally low levels of vasopressin.

Dopamine, a hormone linked to addiction and the reward centers of the brain, also plays a role in attachment. The release of oxytocin and vasopressin during bonding behaviors is associated with the stimulation of the reward centers of the brain and the secretion of dopamine, leading some scientists to conclude that attachment is addictive and that neurohormonal pathways associated with addiction evolved to facilitate social attachment, rather than drug abuse.

Romantic Attachment

Attachment with an adult partner displays many of the same patterns found between adult caregivers and infants. Oxytocin, vasopressin, and dopamine are found in higher concentrations during the early phases of intense romantic attachment and bonding. The concomitant increases of oxytocin and vasopressin with dopamine during the initial phases of romantic attachment (and stimulations of the reward centers of the brain) are consistent with couples' experience of euphoria and may be why individuals feel "addicted" to the person they love. Research indicates men and

women who feel greater support from their partners also exhibit higher levels of oxytocin than do those individuals who do not feel as supported by their partners. The ability to recognize and remember the person one is romantically attracted to is enhanced by the presence of oxytocin and vasopressin (paralleling what happens in the association between these hormones and social recognition memory between mothers and their infants). The human capacity for trusting loved ones is also linked to oxytocin.

Several other hormones are linked to falling in love, including an increase in testosterone in women but a reduction in testosterone among men. The stress hormone cortisol is found to be higher in couples during the initial phases of falling in love. An interesting sex difference associated with social attachment is that vasopressin in men tends to heighten bond formation with both infants and adult partners and increases aggressive behaviors toward others. In mammalian animals, increased levels of vasopressin in the males are linked to territoriality and guarding—all behaviors that could be associated with protecting female partners or offspring.

There is little research on hormones associated with other kinds of social attachment beyond parents and their infants or romantic bonds between adults. However, what the field knows about the complex relationship between hormones and love suggests that the formation and maintenance of social attachment is rewarding and is enhanced because of the action of hormones.

Sexual Behaviors

Love and sex are frequently considered two sides of the same coin; however, the hormonal substrate of relationships highlights the different (if overlapping) roles these two kinds of behaviors play in relationships. As indicated, attachment and love are most frequently linked to oxytocin and vasopressin. Sex-related behaviors are more closely associated with the sex hormones (also called sex steroids).

The origins of sex begin during fetal development when all humans have a female structure. During the second trimester of pregnancy, for males, the influx of fetal testosterone induces masculinization of the brain. The hormonal changes

that lead to the masculine brain are different than those testosterone-associated triggers that result in the distinct male body and gonads. Puberty occurs when circulating sex hormones reach adult levels and children become biologically and sexually mature. For men, with adult levels of testosterone and sexual maturity comes sexual desires and what is termed *mating effort*—a heightened amount of competitive aggression toward other men and an increased interest in sexual consummation. When adult men have suppressed or low levels of testosterone their sexual appetite declines. High levels of testosterone in men is linked to aggression and greater effort to exert dominance in their interactions with women partners. This dominating behavior by high-testosterone men is associated with more aggressive relationship conflict, poorer relationship quality, and a greater rate of divorce.

The contributing roles of testosterone and oxytocin in men's sexual behavior is linked to the nature of their relationship (or lack of relationship) with women. Men may form more permanent bonds with women because of the unique character of women's sexual receptiveness. Unlike other mammals, human females are sexually receptive not just when they are at peak fertility, but throughout their monthly cycle, leading theorists to suggest that this "hidden" ovulation may result in human males investing more time in forming a permanent bond to achieve reproductive success (i.e., having children who live to have their own offspring). This bonding behavior (attachment) in men appears to be associated with greater levels of oxytocin and lower levels of testosterone. There is a drop in testosterone in men when they are falling in love, when they are in committed romantic relationships, and when they make the transition to fatherhood. There is an increase in testosterone in men around the time of divorce but a decrease in testosterone again once they remarry. Men who are sexually attracted to only their wives have lower levels of testosterone than do married men sexually attracted to women outside their marriage. Fathers with lower levels of testosterone are more responsive to the cries of newborn babies. Thus, heightened levels of testosterone appear to be associated with men's pursuit of sexual relationships and lower levels of testosterone (in combination with increased levels of

oxytocin) are linked to social bonds with a mate and paternal behaviors.

Female sexual desires in humans are more complex than for males and not as well understood. There are conflicting research findings about whether sexual desires for women peak around the time of ovulation when estradiol (an estrogen) and testosterone levels are highest. Some evidence suggests that testosterone levels in women are high before, and after, sexual intercourse and during physical cuddling. Research also indicates that oxytocin may play a significant part in women's sexual desire and sexual pleasure, perhaps more of a part than oxytocin plays in men's sexual desire and pleasure. Given the strong association between oxytocin and attachment, this increased role for oxytocin in women's sexual behavior is consistent with evolutionary theories that suggest attachment has a more important role in women's reproductive success.

The source of these differences in sexual desire between men and women is thought to be partly the result of contrasts in the organization and structure of male and female brains. For example, in some female mammals, such as rats, the infusion of oxytocin into sectors of the brain with oxytocin neuroreceptors increases sexual behavior, but only if these females have higher levels of circulating estrogens. However, more sophisticated ways of measuring neurohormonal activity in the brain are needed to provide fuller understanding of the interaction between hormones in women's and men's sexual desire.

One of the unique qualities of humans, noted by virtually all scientists when discussing the nature of hormonal influences on relationships, is that attraction, attachment, and sexual desire cannot be simply explained by the biochemical interactions of these chemical messengers in the brain and body. Hormones may be necessary for building human relationships, but they are not sufficient for such bonds to be created. The interaction between higher cortical processes of the brain, emotions, cultural context, and developmental experience most likely play the greatest role in our choice of whom to build relationships with and the strengths of those relationships. Nonetheless, hormones help facilitate or damage our connection to other people.

HOSTILITY

Individual differences in anger, hostility, and aggressiveness have always been of interest to basic and applied behavioral scientists, given the importance of these aspects of emotion and social behavior in many different domains—including personal relationships. Much of the recent interest in this topic stems from findings that these personality traits are associated with reduced longevity, increased risk of death, and the leading cause of death in industrialized societies—cardiovascular diseases such as coronary heart disease and stroke. The health consequences of hostility may involve the fact that these personality traits are also associated with difficulties in personal relationships, such as low social support, marital strain, and risk for divorce. Strain, disruption, and low support in personal relationships, in turn, confer increased risk of premature mortality and specific serious health problems such as cardiovascular disease. This entry discusses the association of hostility with health, mechanisms underlying this association, and the potential health benefits of interventions that modify this trait.

The term *hostility* has both a general and a specific use in this literature. In the specific sense, it

refers to a collection of cognitive characteristics involving negative attitudes toward others, primarily consisting of ill will, a tendency to denigrate others, and enmity. Closely related traits include cynicism, mistrust, and a hostile attributional style. *Cynicism* refers to the belief that people are generally motivated by selfish concerns rather than by genuine concern for others, and *mistrust* is the expectation that other people are likely to be sources of mistreatment. A hostile attributional style involves the tendency to view the actions of others as reflecting aggressive intentions. Hence, as a cognitive trait, hostility involves the a desire to inflict harm or see others harmed, a relational view of being in opposition to others, the expectation that other people are likely sources of wrongdoing, and a tendency to devalue their motives and worth.

These cognitive or attitudinal traits often co-occur with affective and behavioral characteristics, consistent with the use of hostility in the more general sense. For example, *trait anger* refers to the tendency to experience anger frequently and intensely, often with little provocation and for a prolonged period. Related emotional traits are the tendency to experience resentment and contempt for others. Aggressiveness refers to the tendency toward verbally or even physically hurtful, attacking, or destructive actions. Although *hostility* refers most precisely to the cognitive facet of this interrelated set of traits, the term is sometimes used to refer to the overall set of cognitive, affective, and behavioral characteristics.

For centuries, medical writers have speculated that hostile personality traits contribute to the development and often lethal outcome of cardiovascular disease. The earliest descriptions of coronary syndromes in the medical literature also contained speculations that psychological stress and strong negative emotions such as anger contributed to the disease. Current interest in this hypothesis began when researchers attempted to identify specific unhealthy elements within the broad and multifaceted Type A coronary-prone behavior pattern, comprising achievement-striving, competitiveness, impatience and time-urgency, excessive job involvement, as well as easily provoked hostility. Decades of subsequent research have produced mixed but generally converging evidence that hostility, anger, and related traits are associated with reduced longevity, atherosclerosis,

incident coronary heart disease, recurrent coronary events, stroke, and death from cardiovascular disease.

These statistical associations raise questions about underlying mechanisms. Genetic factors and unhealthy behavioral lifestyles (e.g., smoking, physical inactivity, imprudent diet) likely contribute to the health consequences of hostility. However, the nature and impact of personal relationships also seem to be involved. For example, hostile persons report that they experience less social support than less quarrelsome persons report, and low social support is a well-established risk factor for poor health. Further, hostile people report more conflict in close relationships, and behavioral observation studies of marital interactions confirm that trait hostility is associated with greater levels of negative behavior during the discussion of areas of disagreement between spouses. Longitudinal studies demonstrate that these personality traits are associated with increases in conflict and strain in marriage over time. Hence, hostility is not simply a reaction to difficulty in close relationships; it also seems to be a contributing cause.

Psychophysiological research indicates that hostility and related personality traits are associated with cardiovascular, neuroendocrine, and immunologic responses to social situations that could contribute to poor health. For example, unlike more agreeable people, hostile individuals benefit less from social support provided during psychologically stressful situations. Such social support typically reduces physiological stress responses, but hostile persons do not demonstrate this protective effect, perhaps because of their suspicious and mistrusting view of personal relationships. Similarly, hostile persons respond to conflicts with family members such as spouses with enhanced physiological stress responses. Dissipation of these stress responses seems to require more time for hostile persons, and they may also be more prone to display physiological reactivity when they recall and ruminate or brood about prior episodes of conflict and perceived mistreatment. Hence, a general pattern of reduced positivity in social relationships, increased exposure and reactivity to negative interpersonal interactions, delayed recovery from these episodes, and more frequent psychological re-experiencing could combine to produce a generally greater level of chronic physiological activation

and strain on body systems. Repeated over years, this hostile psychophysiology of daily life could contribute to many different serious health problems. However, no studies to date have tested this full mediational account of how personality traits such as anger and hostility lead to poor health.

Psychological interventions intended to reduce stress and related negative traits such as anger and hostility have been found to have health benefits among persons with established heart disease. These interventions teach skills for the reduction of emotional and physiological arousal, modification of attitudes and appraisals of others that otherwise promote anger and other negative emotions, and the development of more constructive skills in managing interpersonal conflicts. Although no studies have tested the hypothesis that interventions designed to reduce anger and hostility can prevent the initial occurrence of cardiovascular disease, there is growing evidence that such treatments can facilitate recovery after coronary events and reduce the risk of recurrent coronary events. Research demonstrating that hostility is associated with increased difficulties in close relationships such as marriage suggests another potentially important application of this research. There is considerable empirical support for several interventions intended to reduce marital distress and improve relationship functioning. Although anger and hostility are often included as targets in such interventions, these are typically not a main focus. Hence, techniques specifically designed to modify individual differences in anger and hostility may be useful additions to relationship therapies.

HURT FEELINGS

Whoever said, “stick and stones may break your bones, but words will never hurt you,” never interacted with other people. In one of the first studies to explore hurt feelings, people describing how it felt to have their feelings hurt often used terms such as *stung* and *crushed*, or they said they felt their heart break. Although some people seem more prone than others to getting their feelings hurt, no one is immune to the emotional and physical pain that often accompanies a critical remark, a forgotten birthday or anniversary, a broken promise, an unreturned phone call, or a betrayal, such as infidelity. Despite the pervasiveness of hurt feelings, surprisingly little research has been devoted to the topic. Only within the last decade have researchers begun to investigate hurt feelings, and these studies have been limited primarily to Western cultures. Unlike some other emotions, hurt is an interpersonal emotion that arises in every relationship, although it is more likely in close relationships than in relationships with strangers. This entry provides an overview of what is currently known about this painful yet pervasive phenomenon, with particular attention to the conceptualization of, responses to, and consequences of hurt feelings.

Conceptualizing Hurt Feelings

People know what it *feels* like to have their feelings hurt, but what are hurt feelings? Depending on the behavior eliciting them, hurt feelings can be either short-term or long-term. Short-term hurt feelings, resulting from behaviors such as negative

comments, inattentiveness, or interpersonal conflict, make the person who is hurt feel bad but are unlikely to have lasting effects on a relationship unless the slights are repeated. Long-term hurt feelings, on the other hand, such as those resulting from infidelity or a related type of betrayal, make the target feel bad and have more negative effects on relationships than do short-term hurt feelings, in some instances leading to the dissolution of those relationships.

Conceptually, hurt feelings seem similar to a number of other types of emotions and, indeed, are often accompanied by other emotions, such as anger, guilt, fear, anxiety, and sadness. However, the appraisals that produce these other emotions differ from those that produce hurt feelings. Furthermore, when participants are asked to write about the experience of having their feelings hurt, they have no trouble distinguishing hurt feelings from other emotional states.

The defining feature of hurt feelings is perceived relational devaluation, the perception that other people do not value their relationship with the target as much as they once did or as much as the target would like them to. A critical comment, for example, suggests that the person making the remark does not view the target as favorably as he or she once did. Similarly, partners who are unfaithful send a clear message that they do not value their relationship with the target as much as they once did. Researchers have found that the amount of hurt people report experiencing varies directly with the degree to which they feel relationally devalued.

Not surprisingly, then, people's feelings are hurt most often by those closest to them. In an adaptation of the old adage that “we only hurt the ones we love,” researchers have found that hurt feelings are perpetrated *most often* by close friends and romantic partners. Rarely is a stranger the source of hurt feelings. On those rare occasions when our feelings are hurt by strangers or acquaintances, the hurt stems from the fact that rejection by a stranger implies an immediate negative evaluation that signals a high degree of relational devaluation. In addition, at times, the closeness and familiarity of close relationships may help inoculate against the sting of hurt feelings. A tendency to give the benefit of the doubt may be present in close, *satisfying* relationships, which attenuates the sort of malicious

attributions that might otherwise trigger perceptions of relational devaluation.

Although most people think of hurt feelings as resulting from direct emotional injury by another person, people may also experience *empathic hurt feelings*, feeling hurt because someone close to them has been hurt. Parents, for example, may feel the gut-wrenching pain of hurt feelings when their child is rejected or emotionally hurt by someone. Empathic hurt feelings are similar to but distinct from compassion. A parent may feel compassion for a friend's child whose feelings are hurt. Yet, the feeling is far different from that accompanying the experience of empathic hurt feelings when their own child is hurt. In addition, the pain people associate with empathic hurt feelings is often worse than that experienced when their own feelings are directly hurt. When another's feelings are hurt, there is often little people can do to help alleviate another's pain. People do not have the ability to soften another person's hurt feelings by reassessing the situation, as they do with their own hurt feelings.

Variations in Hurt Feelings

To experience hurt feelings, something has to happen that is appraised as a sign of relational devaluation. The range of comments and behaviors, however, that can be appraised as relationally devaluing and emotionally painful is virtually limitless. A leading researcher in the area of hurt feelings found the most common types of hurtful messages to be accusations ("You're such a hypocrite"), evaluations ("Going out with him was the biggest mistake of my life"), and informative statements ("You aren't a priority in my life"). The hurt associated with each of these types of messages is not difficult to imagine; however, some messages and behaviors are more hurtful than others. People who have their feelings hurt by accusations or evaluations can at least respond to those accusations and evaluations by refuting the claim or by asking the accuser for specific examples or explanations. At minimum, the target can "save face" by defending himself or herself. When people's feelings are hurt by informative statements, however, such as "I'm attracted to someone else," there is little that people can do to defend themselves. Thus, not surprisingly, research

has found informative statements to be perceived as more hurtful than accusations or evaluations.

In addition, some people are more likely to experience hurt feelings than others are. Although a number of individual difference variables may predict the proneness to experience hurt feelings, a key variable is rejection sensitivity. Individuals high in rejection sensitivity expect that others will devalue and reject them, and, consequently, are more likely to perceive rejection and relational devaluation even when it is not actually present. Thus, they are more inclined to have their feelings hurt than are people lower in rejection sensitivity. Furthermore, relative to people low in rejection sensitivity, people high in rejection sensitivity are more likely to respond with anger and retaliation to the perpetrator, creating a self-fulfilling prophecy by eliciting the very rejection they thought they perceived initially. Interestingly, in some cases, rejection sensitive individuals will preemptively avoid establishing close relationships with others or withdraw from existing relationships to avoid any chance of being hurt in those relationships.

Responses to and Consequences of Hurt Feelings

People react to having their feelings hurt in a number of different ways. Some people blame themselves, wondering what they did to make another person devalue their relationship with them. Not surprisingly, these individuals are likely to experience feelings of low self-worth as they wrestle with feeling rejected and betrayed by others. Others lash out in anger at the individual who hurt them, challenging the other to account for his or her hurtful behavior. Still others more calmly ask for an explanation of the hurtful behavior and may, in turn, forgive the perpetrator. Yet, other individuals acquiesce. Forgiveness is more likely if the perpetrator offers a genuine apology for his or her behavior, if the hurtful behavior is relatively minor, if the issue is of little importance to the target, and if the target does not respond with anger. Despite the variability in responses to hurt feelings, most hurt individuals respond actively, either expressing anger, countering with a hurtful comment, or telling the perpetrator that he or she had hurt their feelings.

The type of response offered varies largely with the perceived intent behind the perpetrator's behavior. Individuals who perceive that the slight was unintentional, the result of an oversight, absent-mindedness, or forgetfulness, are likely to respond by forgiving the perpetrator. On the other hand, people who perceive that the perpetrator intended to hurt them tend to respond by either blaming themselves or, more likely, actively retaliating against the perpetrator. Not surprisingly, compared with those in less satisfying relationships, people in satisfying relationships report being hurt to a lesser degree (e.g., perceive lesser intentionality by the perpetrator) and indicate that hurtful events have less of a negative effect on the relationship. People in satisfying relationships are also more likely to respond in actively constructive ways when their feelings are hurt, suggesting that members of the dyad discuss and work through hurtful exchanges.

Importantly, however, victims and perpetrators of hurt feelings, as with many other emotions, often differ in the perceived intent behind behavior. Victims evaluate hurtful experiences more negatively than perpetrators do and impute more negative intent and less remorse to the perpetrators than the perpetrators assign to themselves. Perpetrators, conversely, surprisingly evaluate the long-term effects of hurtful events on the victim as more severe than victims perceive them to be. Thus, many people who experience hurt feelings because they perceive that another intentionally did something to hurt them may actually be misperceiving the actual motives of the perpetrator.

The consequences that follow hurt feelings also vary with the type of response offered. People who internalize hurt feelings and the cause of the hurt ("what did I do wrong?") often experience emotional difficulties, such as depression and lower self-esteem. Alternatively, people who respond in anger are less likely to experience depression because they are venting their negative feelings. However, because they direct their negative feelings at the individual who hurt them, they more

often experience relational distance and irreparably damaged relationships. If forgiveness follows, damage to the relationship may be minimized.

I

IDEALIZATION

Sara met Burke 2 months ago, but already her head is swimming with thoughts of marriage. They met at a party and immediately “hit it off.” She feels as if they had known each other their whole life, and she believes that they agree on everything because they have so much in common. After only 2 months, she is convinced that he really loves her for the person she is, and that he is the perfect man for her, the type of guy she always wanted. Like Sara, people who are enthralled with a person tend to bend reality and *idealize* their partner. It is not uncommon to hear from a person who is immersed in the waters of romantic love, “He/She is the most wonderful person I have ever met!” Although this statement might be true, it might also indicate that they have not been dating for long. This possibly myopic view of a romantic partner’s strengths or attributes can lead to what was first called *idealization* by social scientist Willard Waller. What is idealization? How has it been conceptualized and assessed? What is the theory behind idealization and its effects on relationships? These questions are the focus of this entry.

Conceptualization and Assessment

Idealization has been defined and assessed in a variety of ways. Two research teams, headed, respectively, by Blaine Fowers and Laura Stafford,

have focused on descriptions of partners or relationships that are laced with unlikely positivity. Thus, individuals may describe their relationship as perfect (e.g., “Our relationship is a perfect success”) and refer to their partner as someone who completely understands them (e.g., “My partner completely understands and sympathizes with my every mood”). Both groups of researchers assessed idealization with *The Idealistic Distortion* scale.

In contrast, Susan Sprecher and Sandra Metts describe idealization as romantic beliefs individuals may have about a potential partner. These beliefs entail unrealistic expectations about liking everything about the partner, being in the perfect relationship, and having a perfect partner who will completely accept, love, and understand one. Sprecher and Metts measure idealization with a three-item subscale of their *Romantic Beliefs Scale*. Their scale is grounded in the idea that people enter relationships with a set of beliefs or schemas about how a relationship should be. The three items making up the idealization subscale are: “The person I love will make a perfect romantic partner; for example, he/she will be completely accepting, loving, and understanding”; “I’m sure that every new thing I learn about the person I choose for a long-term commitment will please me”; and “The relationship I will have with my ‘true love’ will be nearly perfect.” Individuals who agree with these statements display idealistic beliefs because it is naïve to think that a partner will be able to meet one’s *every* need, please one in *every* way, and be *always* loving.

Other researchers have taken a different approach. Yumi Endo, Steven Heine, and Darrin Lehman have compared perceptions of partners with perceptions of the “typical” or median partner. Thus, idealizations (or positive illusions) are defined as occurring when the majority of people rate their partner’s qualities more favorably than the qualities of the typical or median partner. This definition of idealization is based on the idea that it is logically impossible for the majority of partners to be better than the “typical” or median partner for a given quality or set of qualities.

This approach differs from the one taken by Sandra Murray, John Holmes, and their colleagues. These scientists assess idealization by comparing people’s ratings of themselves with their partner’s ratings of them. Here, *idealization* is defined as the partner rating qualities of the target individual more favorably than does the target person him- or herself. Their definition is based on research indicating that ratings tend to be positively biased. That is, people rate their own qualities more favorably than the qualities of the “typical” or median person. Because self-ratings are positively biased to begin with, they represent a conservative standard against which to evaluate a partner’s perceptions for signs of positive bias. They found that idealization positively affected relationship well-being and had a self-fulfilling effect: Idealized individuals also behaved more positively in their relationship.

Finally, Paul Miller, John Caughlin, and Ted Huston distinguish between positive illusions as a cognitive process, in which people interpret their partner’s behavior charitably, and behavioral processes, in which people form an overly positive image of their partner because the partner behaves more positively in the relationship (i.e., puts his or her best foot forward) than with other people. In the latter case, partners may not be around each other enough to view their partner’s undesirable attributes and characteristics in other settings, thus contributing to potentially skewed illusions of their partner in the absence of contradicting evidence. In a recent study, Miller, Sylvia Niehuis, and Huston have separated out these two processes by using people’s perceptions of their partner’s behavior as a standard against which to assess perceptions of their partner’s personality for signs of an interpretive bias. In their 13-year study of newlywed

couples, the authors found that when partners idealized each other, it often promoted more love in their relationship, and there was some evidence that their positive illusions provided a safeguard against further declines in love later on. Nevertheless, further analysis revealed that if partners entered the marriage idealizing their partner, they were not less likely to divorce. Thus, although idealizing the partner may have a positive influence on the relationship, it may not create a high enough barrier to ward off relationship dissolution.

Theory on Idealization

In his classic paper on “The Dating and Rating Complex,” Waller argued that a natural byproduct of courtship behavior is the process of idealization. He defined *idealization* as the process by which a person creates a mental image of the dating partner that has less to do with reality and more to do with the person’s feelings for the dating partner. According to Waller, early in the dating relationship, partners see each other fairly realistically. As the relationship develops and feelings of love for the partner deepen, however, both partners “put their best foot forward,” displaying only some aspects of their personality in an effort to live up to the image they think their partner has of them. It is this “interaction of idealizations” that leads to the “cumulative idealization of the courtship period,” carrying romantic partners further and further from reality. Waller maintained that idealizing partners increasingly lose their ability to make objective, rational, and realistic assessments of each other’s character and personality traits. He warned that marriages formed at the height of idealization may be at risk for later disillusionment because, once married, spouses may be less motivated to continue to engage in impression management. Moreover, with increasing interdependence, evidence of the spouse’s shortcomings inevitably begins to emerge. This lack of congruence between previous perceptions and new evidence may be experienced as threatening because it has the potential to undermine the belief that the partner truly is the “right person.” Some researchers have argued that this is the point at which positive illusions may begin to unravel, leading to later disappointment and disillusionment. Others,

however, suggest that emerging evidence of imperfections may actually fuel the idealization process. That is, people may interpret evidence of shortcomings in a way that helps them maintain a positive image of their partner. To this end, they may use a variety of cognitive strategies, such as exaggerating the importance of their partner's strengths in order to downplay their partner's weaknesses. For example, Sara might embellish Burke's intelligence and writing ability because of his inability to verbally express himself. Another cognitive strategy often utilized is finding evidence of strengths in the partner's weaknesses. For example, Sara might assuage her disappointment in her partner's communication deficiency by attributing it to his strong and stoic nature. Finally, individuals might create "yes, but . . ." refutations that link shortcomings in their partner to greater virtues. For example, Burke's friends might point out that Sara is lazy, whereas Burke might say, "Yes, she is lazy sometimes, but it's nice that she is so laid back."

Is Idealization Helpful or Harmful to Romantic Relationships?

Does idealization early in marriage set up spouses for disappointment, as some scientists have suggested, or does it help protect people from becoming disillusioned? Although research on positive illusions generally finds that dating partners and spouses tend to be happier in their relationships the more they are idealized by their partners, some research suggests that idealization may be associated with greater decline in affection and love early in marriage and later divorce. For instance, research by Niehuis, Linda Skogrant, and Huston suggests that two different illusion processes during courtship may set up spouses for disillusionment early in marriage. The first is characterized by deep romantic feelings for the partner, quickly intensifying intimacy behaviors, and rapidly developing commitment to marriage over the course of relatively short courtships. It is more likely experienced by young couples, in which the female partner becomes pregnant before marriage. Perhaps not surprisingly, these couples' commitment to becoming married wavers relatively often, suggesting that these individuals may have rushed

into marriage without carefully evaluating how well suited they really are to each other. Dating partners who experience this type of idealization likely become disillusioned early in marriage because of their discoveries about their partner and the quality of their relationship. Although deep feelings for each other may protect them early in their marriage, they are likely to divorce later on.

The second type of illusion process is characterized by relationship problems and a hesitancy to commit to marriage. Although partners in these relationships also love each other, their feelings for each other are less deep. Partners in these relationships often take longer before they say "I love you" and before they have sexual intercourse for the first time. They tend to have extraordinarily long courtships, and, unlike most couples who quickly enter into a regular dating relationship, they often date each other casually for a long period of time. Their commitment to marriage tends to waver, and their accounts of how their courtship developed over time often differ vastly. At the same time, many of these couples "test" their relationship by cohabiting before marriage, and they work hard at improving the quality of their relationship. Thus, partners in this type of relationship seem to be acutely aware of relationship problems, but they marry anyway, failing to recognize the implications of these problems for the quality and stability of their marriage later on. Unfortunately, these couples likely become divorced within the first 7 years of their marriage.

Stafford and Andy Merolla also found evidence that idealization may have a negative effect on relationship stability. Although individuals in long-distance dating relationships idealized their partner more, were more satisfied with their interpersonal communication, and evidenced greater relationship stability than individuals in geographically close dating relationships, they were also more likely to dissolve their dating relationship once they were no longer geographically separated. Together with the finding that idealization was also greater when partners had less frequent face-to-face communication, these findings suggest that idealization may be fueled by lack of accurate knowledge of the partner in day-to-day interactions and may have negative consequences for relationship stability.

How do these latter findings fit with research that shows that people who idealize their partner are more likely to establish satisfying premarital and marital relationships, experience more love as newlyweds, and are better able to sustain feelings of love in marriage over time, compared with people who do not idealize their partner? It is not clear yet under which circumstances idealization has a positive or negative effect on relationship stability, but Niehuis and her colleagues have speculated that the association between idealization during courtship and relationship stability may be curvilinear, such that low levels of idealization may be insufficient to weather significant relationship problems, whereas high levels of idealization may reflect lack of accurate information about the partner. Similarly, Lisa Neff and Benjamin Karney have argued that, although most newlyweds idealize each other on a global level (e.g., “I feel positively about my spouse”), they differ in terms of how much their global idealizations are based on accurate, specific perceptions of one another (e.g., the extent to which both partners agree on the target person’s intellectual capability, social skills, or physical attractiveness). In other words, idealization grounded in accurate perception of the partner’s specific qualities (i.e., agreement with the partner’s assessment of his or her own qualities) is associated with greater relationship well-being and stability than idealization based on less accurate partner perception.

IDEALS ABOUT RELATIONSHIPS

How do people know whether they are in a good or a bad romantic relationship? How do people decide whether to go on a date, live together, get married, or look for another mate? One answer to such questions is that individuals’ judgments about a particular person or relationship are based on the consistency between ideal standards, on the one hand, and perceptions of the current partner or relationship, on the other hand. This entry describes findings and research that suggest that, from the beginning to the end of romantic relationships, ideal standards play a crucial role.

Origin and Nature of Ideal Standards

In New Zealand, Australia, the United States, hunter-gatherer cultures in Africa, and in many other countries and cultures, the same factors are important in mate selection: personality factors such as warmth and intelligence, attractiveness and health, and the possession of status and resources or the ability to gain them (e.g., ambitiousness). Moreover, there is remarkable agreement across both genders and cultures about which factors are more important in selecting mates for long-term relationships. Warmth and trustworthiness is rated number one, with physical attractiveness, good health, and status and resources typically coming in a close second.

But why are these particular kinds of mate standards universally important? One standard explanation is that they represent biological evolutionary adaptations, which implies that their presence confers reproductive advantages. A warm and sensitive partner is likely to be a supportive mate and a good parent. A partner with plenty of money and status (or with the ability and drive to attain such assets) will also have the means to look after the partner and the children. These two sets of qualities

signal that the partner can offer good levels of investment for the family over long periods of time. Attractiveness, in contrast, is generally thought to signal good health, physical strength, and so forth (a good-genes factor).

Men and women have somewhat different standards in long-term relationships. Men give more importance to attractiveness and vitality than women; whereas women tend to give more weight to warmth, trustworthiness, status, and resources than men. These findings have been replicated consistently within Western cultures by research using standard rating scales or by analyzing the contents of personal advertisements, and these specific gender differences are widespread across cultures.

These gender differences are explained by evolutionary psychologists using parental investment theory (originally developed by Robert Trivers in the early 1970s). Mothers typically invest more time, energy, and resources in their children than men and are capable of having fewer children than men. Thus, the male's propensity and ability to invest in the children should matter more to women than vice versa. However, culture also plays an important role. Alice Eagly and Wendy Wood, for example, found that as women's empowerment (indexed by their earnings, their representation in legislative government, and their involvement in professional positions) increased relative to men across cultures, women placed less value on the status and earnings of a mate.

However, there also exist large individual differences that operate within gender. This means that, although there are mean differences according to gender in the importance attached to such standards, there also exists considerable overlap in responses. Thus, many women strongly desire a hot, passionate relationship, and many men are preoccupied with the search for intimacy and commitment. Both men and women will also trade off traits in different ways. Some will be happy to accept an individual who lacks ambition and drive if he or she is kind and supportive. Others may be willing to strike up a sexual relationship with someone who is less than honest if he or she happens to be strikingly beautiful. Of course, people have idiosyncratic standards as well, such as the expectation that their future partner will like the Rolling Stones or have an interest in stamp collecting. However, research shows that the standards

held most firmly almost always fall into the three categories just mentioned.

What explains these strong individual (within-gender) differences? Perhaps the major factor causing individuals to attach different amounts of importance to specific ideal categories is how they rate their own mate value. Research shows that these two kinds of ratings (self-perceptions of mate value and the importance given to mate standards) are moderately positively correlated. For example, more attractive people (who also perceive themselves as more attractive) give more importance to the goal of choosing an attractive mate. In contrast, those who tend to see themselves as sensitive and warm give more importance to the goal of finding a mate with similar qualities.

Why then do people not want a perfect 10? Imagine that Mary is assiduously on the lookout for someone who is handsome, remarkably fit with a wonderful body, and rich. First, there are not a lot of people who fit this description. So, Mary is likely to remain single for a long time waiting for Mr. Right. Second, when Mary does meet Mr. Right, he is unlikely to reciprocate her interest because Mary is not a perfect 10. Third, if Mary does form a relationship with such a person, it is likely to be a high-maintenance affair, making Mary feel insecure and inferior, and involving high levels of vigilance to ward off mate-poaching efforts by other women. In short, for Mary to set her standards at such a rarified level is unrealistic and likely to leave her on the shelf, miserable, or both.

Thus, the name of the mating game is to obtain the best deal available given the prevailing circumstances, especially taking into account what the individual has to offer. This process is one principal cause for assortative mating—the tendency for people in existing relationships to be similar to one another in many ways, including physical attractiveness.

Ideal Standards Never Sleep

The role of ideal standards does not stop after a mate has been selected and a relationship is underway. As knowledge of the partner develops and individuals and perceptions change, people continue to evaluate their partners and relationships in terms of how they meet expectations and standards.

The discrepancies between expectations or standards and perceptions of reality are then used to accomplish three key goals in intimate relationships: evaluation, prediction, and control.

Taking the evaluation goal first, research has consistently found that the more closely people perceive their partners to fit their ideal standards, the happier they are. A study by Garth Fletcher and colleagues traced a sample of 100 individuals over the first year of their dating relationships (none had been dating for more than 1 month at the beginning point). Not surprisingly, 50 percent of the sample had broken up after 3 months, but the entire sample evaluated their partners and relationships, right from the beginning, according to the perceived gap between standards and perceptions. The smaller the discrepancy, the happier people were and the less likely they were to break up.

However, individuals who stayed together also tended to adjust their standards to fit their perceptions more closely over time, a finding that has been reported in other research by Sandra Murray following dating couples over time. This kind of process may reflect unconscious rationalizing or what is termed *motivated cognition*. Murray has also reported with longitudinal research that holding biased idealized beliefs of the partner actually become more accurate over time, apparently by encouraging the partner to move closer to those ideals, such as becoming more sensitive and warm. Such processes tend to produce more relationship satisfaction over time for both partners.

Ideal standards are thus not set in concrete, but are flexible entities prone to change over time. They are also applied differently according to the situational context and the goals of the individual. For example, several studies have found that men express much more modest requirements than women on factors like warmth, loyalty, intelligence, and status, specifically in short-term mating contexts. Given that men are more open to casual sex than women, women can afford to be much choosier than men in such a context. However, women as well as men give less weight to qualities that signal good investment in the relationship (e.g., status and kindness) in short-term liaisons.

Overall, there is one quality that neither men nor women will happily compromise on when shifting from a long-term to a short-term sexual relationship—namely, physical attractiveness. This

finding is consistent with the theory that physical attractiveness and good health form the primary “good genes” factor. In a short-term relationship, all one is getting out of the deal (reproductively speaking) are (potentially) the other person’s genes; thus, this finding provides good support for an evolutionary take in the underlying causes for mating preferences.

Relationships are composed of two interdependent individuals. Thus, understanding how ideal standards work needs to go beyond perceptions and standards focused on the self. Mary’s behavior and happiness is not only dependent on the gap between her own standards and perceptions, but is also a function of how she thinks her partner sees her (so-called reflected appraisals). Reflected appraisals exert enormous influence in relationships. If Mary thinks she falls far short of her partner’s standards, this is a recipe for unhappiness and disillusionment. Not that such perceptions are disconnected from reality. Research shows that people are biased to some extent, but that they are also accurately attuned into both what their partners are like and to how they are perceived by their partners in reality (as measured by the self-reports of their partners or observers).

In short, provided prior pivotal expectations are reasonably met in close relationships, the conditions are set for love and commitment to flourish. If reality falls well short of expectations, however, people will experience strong emotional reactions. When people perceive that they fall well short of their partners’ standards, they experience emotions like sadness and guilt. In contrast, if individuals perceive their partners as the locus of the problem, they are more likely to experience anger and resentment. The emotions that people experience when perceptions and standards drift apart also bring the control function into play. Nickola Overall and colleagues found that people are motivated to try and change features of their partners to the extent that they perceive them as failing to meet their own standards.

People use a variety of tactics when trying to change their partners, including nagging, diplomatic suggestions, team approaches (such as going on joint diets), and subtle ploys (buying a get-rich-quick book for the partner’s birthday). Unfortunately, people report poor success rates when trying to make their partners more attractive, sensitive, or

ambitious. This is perhaps not surprising given the difficulty of changing such traits, but relationship satisfaction is enhanced when change attempts are seen as successful. Generally, however, the more strenuously people try to regulate their partner, the unhappier they seem to become. The reason seems to be that when people try to change their partner on central traits, like sensitivity or attractiveness, they also communicate powerful and corrosive messages (reflected appraisals) that their partner is just not good enough.

ILLNESS, EFFECTS ON RELATIONSHIPS

Illness can have many effects on relationships, from contributing to their deterioration to strengthening them. The extent to which illness impacts relationships depends on the duration and

severity of the illness, the characteristics of the ill persons and their partners prior to and during the illness, and the quality of the relationship and other social networks. This entry describes the differential impact of acute and chronic illness on relationships, caregiver burden and coping, the impact of illness on adults and children, and the ways in which illness may affect communication and sexuality.

Acute Versus Chronic Illness

During times of acute illness, relationship members may adapt to the illness by rearranging schedules to provide care or make hospital visits. These changes are often short term, and the relationship roles usually return to the pre-illness state, especially in long-term relationships such as marriage. However, this pattern may not be the case during a severe or life-threatening condition. In these cases, the illness may have a long-term impact even after it has resolved. In the aftermath of a life-threatening illness, one's mortality becomes more salient, and there may be greater incentive to pursue activities that give meaning to life. Thus, one may have an increased motivation to pursue relationships that maximize positive affect and minimize negative affect. Relationship partners may reevaluate the importance of the relationship and other activities given life's finite timeframe. In some cases, partners will take greater appreciation in the time they spend together or may make decisions aimed at enhancing the relationship. In other cases, a life-threatening illness may cause partners to decide to end an unsatisfactory relationship and find new relationship partners that can satisfy their needs for positive affect and intimacy.

In chronic benign illnesses (e.g., chronic musculoskeletal pain), partners often report reduced marital satisfaction after the onset of the illness. Chronic illness may also contribute to caregiver burden experienced by those who provide informal unpaid care, including spouses, adult children, or other family members and friends. Caregiver burden can consist of physical caretaking and financial responsibilities that exceed one's ability to manage within the context of one's own life. Social burden may include limiting or eliminating social activities to care for the loved one. Emotional

burden, including feelings of sadness, anger, and resentment about having to provide care, is also possible. Although not all caretakers experience burden, it can have a negative impact on mental and physical health, the quality of the relationship, and the quality of care. For instance, greater burden is related to an increased likelihood of abuse of the ill person. Although not studied as thoroughly, patients' perceived self-burden on others may also occur. This type of burden consists of guilt or resentment about receiving care from others and may relate to psychological distress and social withdrawal. Burden is reduced when coping skills appropriate to the situation are used.

Coping Skills

Coping skills are generally classified into two types. Problem-solving coping strategies are typically effective in situations amenable to change (e.g., acute illness) and include gathering information about the illness and seeking social support. Emotion-focused coping strategies such as venting distress, putting the problem into perspective, and active acceptance may be better for situations that are chronic and unchangeable. Active acceptance is characterized by a willingness to experience the illness and a realization that the illness does not have to interfere with one's activities. Contrast this type of acceptance with a passive acceptance in which one gives up pleasurable activities because of feelings of helplessness and lack of control over illness. Therefore, one way to counteract burden is to teach patients and family members coping skills directed toward facing the illness.

Several interventions have been developed to improve coping skills among couples and families dealing with illness. When spouses participate in coping skills treatment programs, chronically ill patients experience significant improvements in coping skills and psychological distress. Furthermore, improvements in marital satisfaction during treatment are related to improvements in mental health, which suggests that coping skills not only affect one's ability to cope with illness, but also one's relationships. Family-based interventions may also help children cope with their illness. Children and parents can learn together appropriate coping skills for dealing with different aspects of the illness.

Children and Adolescents

Chronic illness also impacts the relationships of ill children and adolescents. In children and adolescents, parents may take more control of the relationship and the child's behavior in an effort to facilitate healing or management of the disease. Chronically ill adolescents tend to perceive their parents and siblings as being more positive or caring toward them during the illness. The positive changes in the relationship that adolescents perceive include the parents being nicer, friendlier, and more helpful. Greater paternal involvement has also been shown to lead to more favorable outcomes in maternal functioning, marital satisfaction, and family functioning.

Children's illness can also affect the physical and mental health of their families. For example, parents may feel strain from meeting the demands of caregiving and other roles (e.g., paid employment), and this strain may lead to psychological distress and marital discord. Parents may also suffer from feelings of guilt, worry, and helplessness because they may feel at fault for a genetically related disease or because they are unable to take away discomfort or illness. Further, parents may experience fear of their child's mortality.

Illness in parents may also affect the relationship between parents and their children, although many parents report that their illness increased intimacy in the family relationships. Children may be particularly frightened or upset upon hearing about a parent's illness, especially if the illness is life threatening or disfiguring. Hence, parents need to take into account their child's developmental stage when discussing symptoms and prognosis. For example, parents of young children may use simple terms to describe the illness (e.g., *sick*, *tired*), rather than complex diagnostic terms (e.g., *multiple sclerosis*). Parents of older children may wish to discuss the illness in more detail (e.g., "cancer makes some cells grow too fast and they crowd out my healthy cells").

Finally, chronic illnesses in children may also impact friendships. For instance, it may be difficult for children to find peers who can share concerns about the illness, bring normalcy to everyday routines, and tolerate the uncertainty of illness outcomes. Illness in the parent can also impact children's relationships with friends. Children may be embarrassed

by their parent's illness, may be reluctant to bring friends home, or may become more isolated from their friends because of the time and money that is invested in care for the parent.

Impact on Communication

The impact of illness on relationships is greater when individuals feel stigmatized about their illness. Stigmatization may involve fear of contracting the illness as in infectious diseases (e.g., HIV/AIDS, Hepatitis B) or fear of encountering negative feedback from others by associating with people who have visible disabilities (e.g., physical disabilities). It is difficult for persons with illness to communicate about their pain if they believe that their loved ones are afraid of or embarrassed by them. Without communication, it becomes more difficult to cope with the illness, including seeking and evaluating appropriate treatments. Family members and friends, in turn, may avoid talking about the illness or providing support because openly talking about the illness is uncomfortable or distressing.

Persons with nonstigmatizing illnesses also experience communication difficulties because of fears of how other people will react to the information. Individuals may try to protect close loved ones from negative emotions or sadness by limiting the amount of illness-related information they divulge. In addition, people may wish to avoid communicating about the illness because they believe that talking will make them feel worse emotionally. In less close relationships, many people prefer not to let friends and acquaintances know about the details of their illness because it will upset the balance in these relationships.

However, many people, including those in a long-term romantic relationship, approach illness directly as a team and openly communicate about treatment options. This communication has the potential to enhance the relationship even in the midst of negative emotions such as fear. In addition, there may be less conflict about other issues (e.g., parenting, finances) during the illness, which helps couples focus on treating the illness. In these cases, the illness enhances intimacy and helps families find meaning in the illness. However, in other cases, the illness can disturb communication. For instance, if other aspects of the relationship are

neglected and the sole focus is on the illness, there may be deterioration in intimacy and well-being. Well family members may also withdraw from the sick person to avoid negative feelings or to avoid having to engage in caregiving behaviors. Interactions between ill persons and their partners may also become strained if the patient begins to catastrophize or verbalize helplessness about symptoms because family members often judge these emotional responses as aversive.

Even without direct communication about illness, family members and close friends may still be able to infer the effects of illness on the patient based on the behaviors of patients and the personal characteristics of the observers. Inferences can be made based on patients' behaviors such as limping, rubbing the affected area, or facial expressions of pain. The observers' own personal experience with illness may also enhance their ability to detect pain or discomfort in their family members. Observed behaviors and personal experience may contribute to the observers' understanding of the family members' illness and affect the extent to which they engage in empathic responses or instrumental support behaviors aimed at reducing distress in the patient. Thus, intimacy-building behaviors can still take place between the ill person and his or her relational partners even if the patient avoids verbally communicating about the illness so long as the observer is able to infer the patient's experiences.

Impact on Sexuality

Chronic illnesses may also impact sexuality. For instance, disease- or treatment-related fatigue, pain, and treatment (e.g., chemotherapy, antidepressants) can interfere with the sexual response cycle (e.g., desire, arousal, orgasm). Anxiety and depression, including rumination about the illness, may also impact sexual response. Therefore, chronic illness has the potential to negatively affect the frequency and quality of sexual activity for both partners. This negative impact is more likely among couples with poor relationship quality prior to the illness or couples not accustomed to communicating about sex. Health care professionals have the potential to enhance relationships by introducing the subject of sexuality as a valid

concern. Couples may minimize the negative impact on sexuality by openly discussing the impact of illness or finding different sexual positions to accommodate illness-related pain. In fact, many couples report that sex is a source of comfort and intimacy, as well as an affirmation of gender when other gender roles have been stripped away by illness.

IMAGINARY COMPANIONS

Imaginary companions refers to relationships with nonexistent beings created primarily by children. Three phenomena have been described with respect to this term, two of which constitute imaginary relationships: *invisible companions* and *personified objects*. Invisible companions have no tangible

basis, although they may be based on fictional characters or real people; some are completely invented. Personified objects are objects that the child animates, attributes personality to, and generally treats as alive. Some researchers also consider *pretend identities*, or roles that children adopt for extended periods of time (i.e., months), as the creation of an imaginary companion. This form, however, is a role taken on by the child, and thus may not function as a relationship in the same manner as an invisible companion or a personified object. Relationships researchers are interested in imaginary companions because they provide some of the same social benefits to their creators that real relationships do, such as companionship and validation. They also resemble real relationships, in that children claim a sense of interdependence with their imaginary companions and pretend to interact with them frequently, over months or years.

Imaginary companions come in all shapes and sizes. Invisible companions typically take the form of humans (e.g., babies, children, and, less frequently, adults), animals, or monsters, and personified objects run the gamut from common versions, such as stuffed animals and dolls, to more esoteric objects, such as toy trains or a small can of tomato paste. Children sometimes have whole gangs of invisible friends or a family of animated stuffed animals. Pretend identities may be simple, such as an imaginary child, or fantastical, such as Superman. A few sex differences have emerged in the creation of imaginary companions: Boys may be more likely to create pretend identities and girls to create invisible companions. In addition, whereas girls create male and female companions relatively evenly, most boys' imaginary companions are male.

Imaginary companions are described by children as young as age 2 and as old as age 7 and may exist even later in childhood. Although these companions probably vary substantially in sophistication, using the broadest definition of the phenomenon (all three types), approximately two thirds of young children report creating an imaginary companion at some point in early childhood. Some of these children share information about their imaginary companions with others, particularly parents, but the tendency to do so wanes with age.

In general, children with and without imaginary companions do not differ much, even on variables related to relationships, such as the size or makeup

of the children's social networks, number of friends, or family composition. Children who create imaginary companions are slightly more likely than their peers to be firstborn or only children and to have fewer siblings. Some empirical evidence suggests that children with imaginary companions have a penchant for fantasy more so than children without such companions, and the two groups may also differ on sociability. Contrary to media representations of children with imaginary companions, they tend to be less shy and more sociable than others—if personality differences are found at all.

Although precipitating events, such as moving to a new home or the birth of a sibling, are sometimes cited by parents as causing the appearance or disappearance of an imaginary companion, most companions appear and disappear without an apparent trigger. Once created, the ways in which they are manifest in children's lives may be related to their form. Personified objects are often known to many people in the child's life, including family, teachers, and peers, and often accompany the child everywhere she or he goes. Invisible companions, in contrast, are often known only to family members and associated with home.

In addition to the connection between form and manifestation, whether a companion is invisible or personified may also be related to the kind of relationship the companion provides. Invisible companions, for example, often function as friends for children. In other words, these relationships are typically egalitarian, with the child and the imaginary companion providing companionship and intimacy for each other, as well as help and validation. Relationships with personified objects, in contrast, are often hierarchical in nature. In these relationships, children characteristically provide caregiving and nurturance to the object, and it is treated as less competent and knowledgeable than the child. Interestingly, although pretend identities do not provide relationships in the same way that the other imaginary companions do, their form may also dictate their status relative to the child. These identities, especially when created by boys, tend to be powerful and exciting, exuding competence and capabilities that surpass the child's.

Children create imaginary companions for many reasons, and indeed these reasons probably vary quite a bit depending on the child's age and gender. Still, suggestions have been made in the literature

to explain the functions of imaginary companions. First and foremost, imaginary companions are an exciting form of pretend play. Especially for children who enjoy fantasy and who crave social interaction, an imaginary companion might be the perfect way to always have an available playmate. Second, imaginary companions provide a safe and consequence-free forum for practicing social interactions and understanding social situations. Children sometimes imagine conflict with their pretend friends, and some go so far as to invent imaginary enemies. These creations may be efforts on the child's part to understand and manage the difficulties inherent in social relationships or the potentially unpleasant side of interacting with others. Regardless, the empirical evidence is unequivocal in establishing that the creation of an imaginary companion is neither a sign of psychopathology nor an indication that the child is confused about the difference between fantasy and reality. Children readily admit, and sometimes spontaneously volunteer, that their imaginary companions are not real.

INCEST

The term *incest* refers to the marriage and/or sexual intercourse between two individuals considered

to be close kin according to local cultural norms. Although incest typically applies to cases when couples are in fact genetic relatives, it can also apply when couples are genetically unrelated, yet are categorized as kin according to local customs. In one sense, then, rules against incest can be seen as a way to regulate who one marries (and has sex with) within a particular culture. Although *incest* is typically a term used to understand norms relating to marriage patterns, the related term *inbreeding* is used to mark the degree of genetic relatedness between mating partners. Both incest and inbreeding are used interchangeably, yet they refer to slightly different concepts, with incest being a topic of greater interest in anthropology and cultural psychology and inbreeding a topic of greater interest in biology and cognitive science. This entry focuses on the aspect of incest that overlaps with inbreeding: the mating of individuals who are genetically related by virtue of sharing a recent common ancestor.

Why Is Incest Bad?

There are sound biological reasons that natural selection would have led to the evolution of mechanisms to reduce the probability of mating with a close genetic relative. Throughout the evolutionary history of our species, the selection pressures posed by harmful genetic mutations and disease-causing organisms would have severely negatively affected the health and viability of offspring of close genetic relatives. All else being equal, individuals who avoided mating with a close genetic relative and instead mated with someone who did not share an immediate common ancestor would have left a greater number of healthier offspring. Importantly, the negative consequences of incest are enhanced the more closely related two individuals are, with the most severe consequences occurring between individuals who have a probability of .5 of sharing particular genes (i.e., brother and sister, mother and son, or father and daughter). The deleterious effects drop off as two partners become less closely related. Interestingly, in most (if not all) societies, incest between nuclear family members is forbidden or simply absent. In the United States, incest laws vary by state, but most have sanctions targeting marriage and sexual

intercourse with a parent, child, sibling, grandparent, grandchild, niece, nephew, uncle, and aunt. Although some states even sanction first-cousin marriage, none sanctions second-cousin marriage.

A variety of studies have documented the negative fitness consequences associated with incest. For instance, in both humans and nonhuman animal species, incest is associated with an increased risk of mortality, mental deficiencies, congenital malformations, and disease. Given these negative consequences, it is likely that evolution engineered mechanisms to prevent individuals from choosing close relatives as sexual partners. But what might such mechanisms look like?

How Do Humans Avoid Incest?

To avoid close genetic relatives as sexual partners, a well-designed mechanism would require (at least) two types of procedures: (1) procedures that categorize individuals according to their probability of relatedness (i.e., procedures for detecting kin), and (2) procedures that use information regarding kinship to regulate sexual attraction. With respect to kin detection, what cues do humans use? Because we cannot see another person's DNA, the best evolution could do is to use cues that were reliably correlated with genetic relatedness in the ancestral past to compute a probability of relatedness. To the extent that different cues identified different categories of kin (e.g., mother, father, sibling, offspring), different detection mechanisms likely exist.

One cue found to mediate the detection of a particular type of relative, siblings, is childhood coresidence duration. The longer one lives with another person starting from birth, the greater the sexual aversion that develops toward that individual later during adulthood. Furthermore, longer periods of childhood coresidence are associated with lower incidents of adult sexual behavior and greater moral opposition to sibling incest. The effect of childhood coresidence on sexual attraction is known as the Westermarck Effect after the 19th-century Finnish social scientist, Edward Westermarck, who first proposed that early childhood association leads to the development of a sexual aversion later during adulthood.

Two well-known natural experiments provide compelling evidence for the Westermarck Effect.

The first is the communal childrearing practices of the Israeli kibbutzim, where unrelated children were put into children's houses starting from a few weeks after birth and raised together under sibling-like conditions. In these communities, individuals raised together in the same children's house rarely married one another despite the absence of any rules forbidding such unions. This pattern suggests that early childhood exposure influences later sexual attraction.

The second natural experiment testing the Westermarck Effect is the case of Tawainese minor marriages. In this form of marriage, a young bride is adopted into her future husband's family as a newborn and raised alongside him until one day, during adulthood, the parents determine it is time for them to marry. Compared with marriages in which the husband and wife met for the first time as adults, in minor marriages, there were lower rates of fertility and greater rates of divorces and extramarital affairs.

These two experiments point to childhood coresidence duration as one cue that the human mind uses to detect kin and mediate incest-avoidance behaviors. As they suggest, individuals do not have to be genetically related to develop a sexual aversion toward one another. This can be seen in coreared adopted and stepsiblings who also develop intense sexual aversions toward one another despite knowing they are not genetic relatives.

But cues other than childhood coresidence might also play a role in incest avoidance. For instance, seeing one's mother caring for (e.g., breastfeeding) a newborn might serve as a potent cue to kinship. This cue would have only been available for older siblings already present in the social environment and would have been reliable regardless of coresidence duration. But younger children, who are not around to see their mother pregnant and caring for a newborn, might rely on coresidence duration or other possible cues such as facial similarity or olfactory recognition.

Future Directions

Certainly there is much to be learned about the processes mediating how humans avoid incest. The prior discussion illustrates that particular social cues might govern kin detection and the

development of sexual aversions. But many questions remain. For instance, what cues do humans use to detect other types of close genetic relatives: Are they the same as those found for siblings or do they differ? What emotions regulate incest avoidance? What contextual factors influence opinions about incest? How can scholarly understanding of incest-avoidance mechanisms inform the field of child abuse and neglect? If kinship cues are required to activate sexual aversions toward close genetic relatives, it is important to identify which cues operate for each type of family member. Circumstances in which the evolved cues indicating relatedness are absent might lead to greater risks of incestuous unions (e.g., as can occur when brothers and sisters are reared separately or when men marry women with children from another marriage). Last, how does our evolved psychology influence legal codes related to incest? The next few decades promise to shed light on this culturally universal yet underexplored behavior.

INDIVIDUATION

Individuation refers generally to the process by which people render themselves as separate and distinct from others. Researchers of human relationships

have studied individuation from a variety of perspectives, three of which appear to be central in the literature. First, individuation can represent an aspect of a child's separation from and waning dependence on his or her parents. Early theorists asserted the importance of individuation in infancy and during adolescence, and recent research suggests that the failure to successfully individuate is associated with a variety of negative psychological outcomes. Second, individuation describes behaviors that distinguish an individual from his or her surroundings. These behaviors can be reflexive, such as when we are outspoken in front of others, or can be directed toward others, such as when we call someone by name in a crowd. Third, the concept of individuation is closely tied to that of deindividuation. Deindividuation is a process, often induced in groups, through which people feel indistinguishable from others. Feeling deindividuated leads people to exhibit different behaviors than they normally would in social situations, including anger, violence, and lowered self-restraint. Although the subject of individuation has been viewed in several different ways, the study of these domains have implications for the understanding of all kinds of human relationships, from families to large groups. This entry describes the concept of individuation in depth as it pertains to these three perspectives.

Individuation in Development

In 1953, Carl Jung proposed individuation as an important part of normal human development. Later, Hungarian physician and psychoanalyst Margaret Mahler drew on Jung's work to develop a sequence of phases, now referred to collectively as the Separation-Individuation Theory, that guides children's psychological development from birth to age 3. The third phase, called the separation-individuation phase, begins at 4 or 5 months of age. The early part of this phase is marked by gradual sensory development, known as hatching, which gives rise to increased alertness and goal-directed awareness. Infants venture farther from their mothers as their mobility increases, and they begin to experience great joy in performing autonomous tasks while still keeping mother within sight. The child begins to share these new discoveries with mother and seeks social interaction with

her and others. Infants first experience stranger anxiety during this stage, indicating internal conflict between curiosity about new sources of stimuli and the need to check back to mother for security. Love and emotional availability of the mother are key at this stage as the concept of separateness becomes more salient for the child. Late in the separation-individuation phase, the child develops a definite sense of individuality, self-boundaries, and gender identity.

Individuation is also an important goal of late adolescence. Peter Blos claims that a second and higher level process of individuation takes place during adolescence. Like Mahler's conception of early individuation, this second phase is characterized by weakening dependency on and disengagement from family, which allows for the possibility of extrafamilial love and relationships within a broader social framework. At the same time, physical maturation demands the acceptance of an adult sex role. The goal of this process, achieved in normal development at the end of adolescence, is to obtain a clear, stable sense of the self. For some adolescents, failure to achieve successful individuation can result in learning disorders, lack of purpose, procrastination, and emotional shallowness. These psychologically unindividuated adolescents may seek to distance themselves physically from their families, which helps them to avoid confronting their failure to achieve this necessary goal. This represents an unhealthy regression toward the early childhood separation-individuation phase that Mahler described.

An age-appropriate level of individuation is also necessary for normal development of a mature, adult identity, which in turn is requisite for an individual to take on normal adult roles and responsibilities. Parents may resist the attempts of their children to individuate and to progressively take on more adult roles and authority. This kind of parental intrusiveness can stymie normal adolescent development and produce conflict, and the resulting developmental delays can in turn produce more intrusiveness and escalate conflict between parents and teens. In its most extreme form, called *enmeshment*, parental intrusiveness causes for the adolescent a blurring of boundaries between self and other and a preoccupation with parents' satisfaction. Outcomes for enmeshed adolescents include low self-esteem and difficulty forming friendships

and romantic partnerships. Problems with separation and individuation are also shown to be risk factors for eating disorders, including anorexia nervosa and bulimia, mediated by poorly developed senses of self-esteem, autonomy, and control.

In addition to relationships within the family, individuation plays an important role in the development of any close relationship. Successful individuation helps to maintain a balance between the individuality and the connectedness of the partners in a dyadic relationship. Individuality represents self-assertion and separateness, both of which enable people to express unique opinions and assume responsibility for them. Connectedness encompasses mutuality and permeability. Mutuality is important for developing empathy and feeling respected for one's own beliefs, whereas permeability, one's openness to the ideas of others, is important for perspective-taking. Thus, individuation is essential for adjustment within families and continues to have effects for close relationships throughout the life course.

Individuating Behaviors in a Social Context

Individuation is also viewed as a social phenomenon exhibited by people throughout the life course. In this sense, it encompasses a set of behaviors that make a person feel distinguished from his or her surroundings. Social psychologists study such behaviors and their implications in social contexts. For example, Christina Maslach examined situational cues that encourage individuating behaviors. Individuating behaviors can be self-directed (e.g., raising one's hand to ask a question, publicly challenging a speaker, dressing unusually) or can be other-imposed/situation-driven (e.g., being identified by name, being invited to express an opinion). People individuate when they anticipate a reward or support from their social group, but tend not to individuate when they anticipate punishment. Individuating behaviors do not always manifest themselves in isolation, but rather may be part of a group's collective effort at individuation, such as the case with groups ranging from Greenpeace and the Veterans of Foreign Wars to more countercultural groups including the Hell's Angels and the "Jesus freaks" of the 1960s and 1970s.

Individuation requires both social awareness and self-monitoring. Individuating behaviors are not always successful, as is the case when other group members follow suit. To determine how to differentiate oneself from the norm, one must be able to perceive both oneself and the social environment accurately and compare the two. Once the norm has been accurately perceived, individuation also requires deviance from it. This would suggest that nonconformity, willingness to violate authority, and even exhibitionism may also be related to individuation. This connection could bring with it implications for socially mediated behaviors, such as aggression and altruism.

Research conducted with North American and European samples has shown that individuation in social situations can yield positive social outcomes, such as increased social impact and leadership. However, the evidence suggests that the relationship between individuation and leadership is culturally bound. The primary goals of socialization in individualistic cultures (e.g., the United States) are independence and autonomy, whereas the preservation of harmony and "fitting in" are the primary socialization goals of collectivistic cultures (e.g., East Asian countries). A popular saying in the United States illustrates this phenomenon: "The squeaky wheel gets the grease." In Japan, rather, an analogous saying goes, "The nail that stands out gets pounded down."

The same individuating behaviors that reap benefits for people in individualistic cultures sometimes bring about negative consequences for those in collectivistic cultures. One key difference between these two results lies in whether the behavior is seen to reflect leadership qualities or as seeking attention for self-promotion. Certain individuating behaviors have different meanings in collectivistic cultures than they do in individualistic cultures. In the United States, for example, individuating behaviors, such as performing on stage in front of a large audience or giving one's unsolicited opinion on a controversial issue, are interpreted as signs of leadership. In China, however, some behaviors are interpreted as indicators of leadership (e.g., performing on stage), whereas others are interpreted negatively as attention-seeking (e.g., giving an unsolicited opinion).

What can we learn from cross-cultural studies about individuation? Contrary to popular views in

the West, it is not always outstanding to be standing out! It is important to be sensitive to cultural differences in perceptions of individuating behaviors. What would be perceived by someone from an individualistic culture as displaying leadership could be interpreted by someone from a collectivistic culture as attention-seeking. For example, many courses taught in American schools and universities require students to actively and spontaneously participate in class discussions by volunteering one's own opinions. This sort of policy may be biased against students whose culture tells them that individuating oneself in this way is socially undesirable.

The Flip Side of Individuation: Deindividuating Behaviors

Leon Festinger, with colleagues Albert Pepitone and Theodore Newcomb, published the first article on the subject of deindividuation in 1952. The authors used the term *deindividuation* to describe a state in which individuals behave differently in groups, and particularly in crowds, than they do when they are alone. When groups afford individuals some degree of anonymity, they tend to be less restrained and inhibited, and they allow themselves to indulge in behaviors in which they would not otherwise indulge. For example, people are more likely to speak openly about their feelings of anger when their identity is anonymous. Further, people are more satisfied with groups that offer a reduction in restraint, suggesting that such groups satisfy needs normally inhibited by those socially imposed restraints.

Philip Zimbardo highlighted an important distinction between the concepts of individuation and deindividuation. He claimed that individuation comes about merely by making choices, by exercising free will. These choices create a social contract through which the decision makers are held responsible for the consequences of their choices. In so doing, the decision makers become distinct from, and in some cases set themselves up in opposition to, those in their social groups who deindividuate by following along with the group's actions.

Although exercising free will may entail individuation, succumbing to the power of the situation can give rise to deindividuation. Zimbardo's

1971 Stanford Prison Experiment provides a startling example of how a given situation can lead normal, psychologically healthy individuals to deindividuate and engage in unusual behaviors. The experiment required volunteers to play the randomly assigned roles of either prisoners or guards in a make-believe prison for two weeks on the Stanford University campus. Both prisoners and guards were given uniforms to deindividuate them. Prisoners wore matching smocks, hats, and flip-flops and were identified only by number. Guards wore matching uniforms, whistles, and dark sunglasses. Subjected to this situation, both prisoners and guards soon became violent toward each other. During the first few days, prisoners rioted, guards began tormenting the prisoners by spraying them with fire extinguishers, and prisoners chided each other for complaining. Participants began to show signs of severe emotional distress, and within 6 days, the experiment was called off. The deindividuating effects of the situation were so powerful that Zimbardo had to remind some prisoners of their true identities.

Zimbardo also sought to find evidence of deindividuation that would distinguish it from related patterns of behavior driven merely by phenomena such as contagion, aggression, and disinhibition. To do this, Zimbardo conducted a follow-up study to Stanley Milgram's earlier experiments on obedience, this time adding the variable of deindividuation. As a group, female students who were all wearing hoods in order to deindividuate them were willing to deliver twice the intensity of electric shock to the ostensible "victims" as women in groups who were wearing name tags and no hoods. From this and other experiments, Zimbardo concluded that any situation that deindividuates people and provides any sort of permission for aggression can enable otherwise moral, rational people to commit acts that they would never expect of themselves.

More recently, Zimbardo and others have applied the concepts of individuation and deindividuation to a vast range of examples of human maltreatment, including historical acts of the Ku Klux Klan and, more recently, the abuse of prisoners at the Abu Ghraib prison in Iraq. In the military, both the requisite wearing of uniforms by soldiers and the intentional depersonalization of the enemy are both acts of deindividuation designed for specific results.

Combining stressful, fear-inspiring situations with these purposeful traditions of deindividuation can produce tragic results.

However, the effects of deindividuation are not restricted to extreme cases. Other-imposed or situation-dependent deindividuation can set the stage for trick-or-treaters to cause mischief on Halloween, Mardi Gras revelers to behave wildly, and Internet chatroom users to be dishonest and vulgar in their “chats.” In all of these cases, everyday and extreme, normal people engage in personality-atypical behaviors without noticing the power of the situation.

INFANT–CAREGIVER COMMUNICATION

Before infants use words, they engage in rich communication with their caregivers through gestures, vocalizations, emotional expressions, and in other ways. This entry describes the development of infant–caregiver communication during the first 2 years of life, including the baby’s grasp of interactive practices, and how developing communication is influenced by the child’s growing awareness of the adult as a psychological being who communicates and receives communication from the baby.

Sally, 3 months old, is strapped into her bouncy seat, and her mother is sitting across from her. Sally coos and smiles at her mother, and her mother responds with a wide-eyed smile and a responsive coo as Sally bounces. Her mother laughs and brings her head closer, saying, “You like that!” Then the telephone rings. Sally’s mom answers and begins to talk. Sally makes another squeal, but her mom says, “Shh. Shh.” and pats Sally’s belly, then moves her hand away and starts writing on a pad of paper. Sally kicks her feet again and smiles at her mom, but gets no response. After a few more attempts, Sally turns away with a sober expression and brings her fist up to her mouth. A few moments later, Sally’s mother hangs up the phone. “Where were we, little one?” she says to Sally, but Sally keeps her head turned away. Her mother starts singing a soft song, and after a few moments Sally turns toward her mom’s voice. Sally smiles and kicks her feet when the song is over. Sally’s mother responds with a smile.

This example of face-to-face interaction is characteristic of 3- to 6-month-old infants and their caregivers. At this early age, infants are in tune with the social world and are practicing the rules of social interaction that include their growing abilities to take turns and engage others in positive interactions through these simple forms of play. Through these interactions, infants also start to develop a psychological awareness of others that will blossom at the end of the first year and throughout the second year. It is partly through the infant’s developing psychological awareness that others are communicative partners and recipients of the infant’s communicative efforts that caregiver–infant communication develops and takes new forms.

The First Six Months: Face-to-Face Interaction

Infants enter the world primed for social interaction. Shortly after birth, infants show preferences for faces over other visual stimuli, for their mothers' faces over other faces, and for their mothers' voices. In addition, newborns are already engaging the social world by expressing needs through crying and other affective cues. Despite this, the sensory world of the infant is characterized by a lack of visual acuity and perceptual organization. Add a lack of mobility, rapidly changing behavioral states, and long hours spent sleeping each day, and it is not surprising that infants are not capable of engaging others in coordinated interactions until weeks of physical and sensory development take place.

As infants enter the third month, they begin to distinguish facial features more clearly and can recognize familiar faces based on these refined perceptions, and they are prone to longer periods of attentive wakefulness. At this age, caregivers and infants begin to engage in coordinated face-to-face play. This type of interaction is characterized by periods when the caregiver and infant interact in close proximity with few outside distractions. Face-to-face interaction provides unique opportunities for infants to learn about turn taking, emotions, emotion regulation, and trust in important adults through the caregiver's responsiveness.

The opening vignette is a characteristic example of face-to-face play. Through such interactions, Sally was learning to take turns during communication, a common characteristic of verbal exchanges, as well as learning about emotions. For example, Sally's positive expressions were followed immediately by her mother's positivity. If Sally had expressed negative affect during their bouncy game, her mother likely would have responded with surprise or she would have ignored Sally's affect to keep the interaction going, sending Sally an implicit (and perhaps unintentional) message that negative affect is not appropriate at that time. Researchers have found these to be prototypical responses of mothers toward their infants' emotions during face-to-face play, evidencing the role of mothers in regulating their infants' emotions at this young age. Researchers have found that infants' emotional expressions become more positive through these repeated interactions in which mothers' affective responses

contingently guide their infants' emotions and engage their babies in emotional reciprocity.

Face-to-face play is often described as an exquisite dance characterized by synchronized coordination between mother and infant. By contrast, careful studies have shown that much of the time, mother–infant face-to-face interaction is characterized by miscoordinated states, when the infant and mother are not making eye contact or positively interacting. As long as this miscoordinated interaction is repaired through each partner's contribution to sensitive reengagement (such as the reengagement between Sally and her mother), infants will learn trust in their caregivers and will also learn that the self is an effective agent in social interaction. Miscoordinated interactions can be caused by external (such as a phone call or an interruption by a sibling) or internal (such as an infant's overarousal or a mother's intrusiveness) occurrences and can last for as little as a few seconds.

Researchers have manipulated mother–infant face-to-face interactions with the "still-face procedure." In the still-face procedure, mothers pose an expressionless, nonresponsive face in the middle of a typical face-to-face interaction. Researchers have been interested in the infant's behaviors during the mother's still face, as well as the mother's and infant's behaviors during the reparation period after the mother resumes typical interaction. Findings from the still-face procedure have shown that infants express decreased positive affect and more negative affect, more self-focused behaviors, and withdrawal behaviors during the unresponsive period. Some infants at first try to positively engage the still-faced partner through smiles and behaviors that previously elicited positive interaction (e.g., reaching, vocalizing, leaning toward the partner), but these behaviors are short-lived when they fail to achieve a response. Upon reparation, infants become more positive, but continue to express subdued affect in comparison with their earlier typical behavior. These findings provide evidence that infants have social expectations from as young as 2 months of age. Like Sally in the vignette, infants expect responsivity from social partners and continue to represent the dysfunctional interaction after it occurs (as evidenced through their continuing expressions of subdued affect), showing that infants are not acting solely on the basis of present stimuli in their immediate perceptual world.

Thus, both infants and caregivers are social agents with social expectations of their partners in interactions during the first 6 months of life. Infants are early aware that interactions are dynamic and require shifts in behavior to alter the behavior of the adult. The caregiver acts in ways that respond to and shape the infant's behavior, and the infant similarly responds to and shapes the caregiver's behavior. Through these reciprocal interactions, infants develop the foundations for a sense of self and other, as well as an awareness of others' emotions and social initiatives and their own self-regulatory behaviors.

The Second Six Months: Communication Across a Distance

As infants near the end of the first year, the onset of locomotion shapes how they interact with others. The face-to-face interactions of early infancy are replaced by faster negotiations involving facial and bodily expressions and verbalizations that must be communicated over a distance. With the onset of mobility, infants must negotiate a constantly changing world with new physical obstacles, perceptual cues, and potential threats to the infant and challenges to the caregiver–child relationship. These advances are accompanied by several changes in infant–caregiver communication and in infants' psychological awareness of others. Specifically, infants begin to guide both the behavior and the knowledge of others through pointing out referents to social partners, and infants begin to use the emotional communications of others to guide their own actions through social referencing.

As infants begin to crawl, they become more independent and agentic, with firm goals guiding their behaviors. Simultaneously, they use emotional information to infer the goals and intentions of others. If an adult positively emotes while looking at an object, the infant infers that the adult likes the object and expects the adult to take it, comment positively about it, or act in other consistent ways. Research on pointing behaviors also evidences infants' understanding of others' mental states. If an adult is unable to find a desired object, 12-month-olds will point out the correct location of the object, showing that they understand that others have specific goals underlying their behavior.

Infants use pointing for a variety of social purposes (as do adults). They may point to provide information for another, known as protodeclarative pointing. Protodeclarative pointing may be used to identify any event of interest to either the adult or the infant. For example, an infant sees a bird in the tree and points at it. His grandmother sees the infant point and says, "Wow, look at that bird!" In essence, this pointing is used to create joint attention around a common object or event of interest. In contrast, protoimperative pointing is used by the infant to gain an object or item. For example, an infant wants the banana but cannot reach it so he points to the banana. His grandmother sees this and retrieves the banana. In essence, the infant uses this pointing to create shared intentionality—in this case, using the adult as a social tool for gaining objects or items. With both types of pointing, infants are actively changing the adult's knowledge and motivation, creating shared goals and intentions between the child and adult.

Research has shown that 12-month-olds point to share attention and an affective or intentional attitude about objects and events. If an adult does not attend to an event of obvious interest, the infant will point to the event for the adult. In addition, 12-month-old infants point out novel objects to adults based on what is novel to the adult rather than to the infant. This behavior requires an understanding that the adult has different perceptions than the self and that expressions of surprise are often directed toward novel objects. Through pointing, therefore, infants actively enter the intentional states of adults as well as engage adults in their own intentional states, creating shared intentionality. It is evident that this is a nonegocentric social capability in 1-year-olds.

Like pointing, social referencing appears in the second half of the first year, but is not measurably robust until approximately 12 months of age. Social referencing describes how, when they are faced with an ambiguous or uncertain situation, infants look to adults' emotional expressions and use these expressions to guide their response. For example, when a stranger approaches, a 12-month-old might look to his mother's reaction before deciding whether to approach the stranger. If the mother expresses concern or fear, the infant would likely avoid the stranger, but if the mother expresses happiness or reassurance, he might instead approach

the stranger. Social referencing thus requires some knowledge of others' attention, emotion, and mental states and the association among them.

Although social referencing does not appear robustly across all types of situations, it is a crucial tool for communication in situations of uncertainty. The same infant might reference the mother in an ambiguous physical situation, such as using an unstable stool to pull to standing. Needless to say, the development of infant mobility is also characterized by increases in caregiver prohibitions on infant behaviors in ways unencountered earlier in infancy and that also heighten infants' sensitivity to distal emotional cues. The new demands on infant–caregiver communication created by the infant's developing capabilities are accompanied by a new awareness of others' mental states and important achievements in creating shared intentionality.

The Second Year: Sharing Others' Intentions and Goals

The second year is characterized by immense changes in the infant's social and emotional capabilities. Communication expands from the non-verbal referencing of objects and events to verbalizing nouns, actions, and emotions by the end of the second year. As in the first year, advances in infant–caregiver communication transform social interaction, and they derive in part from growth in the child's understanding of others' intentions and goals, as well as the developing capacity to create shared intentionality with the adult.

The rudiments of shared intentionality emerge with pointing behaviors during the first year, and they develop into new and more complicated behaviors as infants enter into others' goal states during the first half of the second year. Infants begin to imitate adults' acts with no apparent purpose other than imitation, and they will imitate arbitrary behaviors that they have seen days earlier. More important, infants begin to imitate adults' *intended* actions even if the adult did not succeed in what they intended (e.g., putting a ball in a basket that the adult had tossed but missed). Another indication of growth in shared intentionality is the emergence of helping behavior. By 14 months, infants help others with basic tasks, such as handing

an adult something that was dropped; by 18 months, infants help in a wider variety of tasks, such as opening a cabinet for an adult whose hands are full. Taken together, these behaviors indicate that infants are able to infer others' intentions and enter into another's intentional state, creating shared intentionality around a common goal.

Development in shared intentionality is the means for two further advances in infant–caregiver communication later in the second year. First, pretend play appears in infant–parent interaction close to the second birthday as a shared social activity. Two-year-olds rarely engage in pretend by themselves, but they will share an adult's pretense with smiles and knowing looks, showing that they are entering into the adult's imaginative activity when they stir a bowl with a banana or use the banana as a telephone.

Second, language ability also flourishes during the second year and also as the result of shared intentionality. A toddler's ability to understand and use words derives in large measure from comprehending the intentional state of the adult they overhear using those words. When father says "Look at the cute kitten!" in the presence of a stray cat, an 18-month-old can understand the referential intent of the word *kitten* only by astutely interpreting the adult's gaze direction, emotion, and intentional behavior to deduce that the word refers to the animal before them, rather than to the sidewalk, the grass, or even the kitten's size or color. The toddler's later use of the same word to refer to another kitten when she is with her mother reflects another example of imitation—and another illustration of the capacity for shared intentionality in the second year.

Conclusion

Infants' understanding of the emotions and information contained in others' minds shapes developmental changes in caregiver–infant prelinguistic communication. Over the first few months of development, infant–caregiver communication is characterized by need-based interactions. As infants enter the third month, their longer periods of wakefulness and newfound perceptual abilities allow for coordinated interactions, but they are also marked by periods of miscoordinated communication and

recovery. During these interactions, infants learn communicative tools and important information about others' emotional states. Both infants and caregivers are active agents in these interactions, mutually acting to shape the emotions and behavior of the other. These face-to-face interactions wane as infants become more mobile and require communication across larger spaces regarding more complex situations. Infants use pointing to create joint attention, and they combine pointing and other gestures to create shared intentionality with others around interesting and desired objects and events. In addition, infants use others' emotional expressions to guide their behavior in ambiguous situations, evidencing an understanding that others have important information to convey in their assessments of such a complex world. During the second year of life, infants develop a more sophisticated understanding of others' goals and intentions, allowing for action-based communication around the intentions of others. These provide the avenue for more complex imitation and helping behavior, shared pretense, and the development of language.

Infants are thus capable of much more than we once thought in their ability to understand the emotions and information provided by their caregivers through both direct and indirect communicative acts. These communications provide the foundation for psychological growth as infants approach the development of linguistic communication and develop an even more complex understanding of others.

INFATUATION

Infatuation is a state characterized by intense feelings of passion toward a specific individual. The term *infatuation* typically refers to the early stages of romantic love, before the infatuated individual has had a chance to get to know or develop an intimate relationship with the love object. Colloquially, infatuation is frequently associated with youth and suggests an irrational, capricious approach to love. Although some consider infatuation to be a special, perhaps early or intense form of passionate love, researchers often use the term *infatuation* interchangeably with *passion*, *passionate love*, *limerence*, or being *in love*. Therefore, this entry reviews research and theory on infatuation and these associated terms.

Features of Infatuation

When individuals are infatuated with a potential or current romantic partner, they frequently exhibit any or all of an assortment of features. For one, infatuation is often characterized by persistent, intrusive thoughts about the love object. These thoughts may take on a fantasy-like quality, or, alternatively, they can be anxious ruminations that are distracting and distressing to the infatuated

individual. Frequently, the character of these intrusive thoughts will ebb and flow, focusing at one moment on the possibility that one's feelings are reciprocated and the next moment on the possibility that they are not. This volatility contributes to the emotional turbulence experienced by infatuated individuals, who tend toward euphoria when the love object demonstrates romantic interest in them and toward despair when the love object is insufficiently responsive. Infatuated individuals also commonly idealize the love object, worshipping his or her positive qualities while only indifferently acknowledging his or her negative qualities. Finally, infatuated individuals direct their passions toward only one potential partner. Only rarely do individuals experience strong infatuation toward multiple individuals, and, consequently, they yearn for their love object to reciprocate this exclusive desire. Although not all of these features are necessarily present in every infatuation, the more acute the infatuation, the more likely it is that these features will be present and pronounced.

Another important component of infatuation is sexual desire. In most cases, individuals become infatuated with potential romantic partners who are of the sex that they prefer romantically, and sexual fantasies are often present in infatuated individuals' persistent thoughts about their love object. (Exceptions to these rules are also important in understanding the nature of infatuation and are reviewed later.) In one study, participants named people with whom they were currently "in love" and reported that, in 87 percent of the cases, they also experienced sexual desire for these same individuals. However, sexual contact is rarely the central stated goal of an infatuation. Instead, infatuated individuals long for moments of emotional union with the love object; sexual encounters do not necessarily lead to emotional unions, and emotional connections can frequently be achieved through nonsexual means. Also, given that people can feel sexual desire (but not infatuation) for a number of different individuals at the same time, sexual desire alone is insufficient to generate or sustain an infatuation.

Infatuation is more likely to emerge during the early stages of a romantic or potentially romantic relationship. But infatuation is unlikely to last forever: Such intense passion has a tendency to fade

over time in most romantic relationships. There are several reasons for this decline. For one, relationships are initially exciting because people's self-concepts expand to incorporate their romantic partners, but this excitement fades once the self-expansion process runs to completion. In addition, it takes a certain measure of anxiety and uncertainty to maintain the infatuated state, and as time passes, people typically accrue enough evidence to confirm or refute the possibility that a love object desires the self in return. Tumultuous, off-again/on-again relationships that perpetuate confusion about romantic partners' feelings and intentions probably have the best likelihood of sustaining infatuation. (Of course, such relationships probably do a poor job of sustaining interpersonal trust and security!)

Conceptual Frameworks

Many social-psychological theories have explored infatuation and related constructs. One relevant and well-known theory of love is Sternberg's triangular theory. Sternberg proposes that love has three components: passion, intimacy, and decision/commitment. The passion component refers to the experience of arousal and sexual desire; the intimacy component refers to feelings that promote closeness, bonding, and connectedness; and the decision/commitment component refers to the decision to love a particular individual and the commitment to maintain that love. Different types of love emerge from different mixtures of any or all of these components, and each component may be present in varying degrees. Sternberg suggests that infatuation is a kind of love that exists when only the passion component is present. That is, individuals are infatuated when they experience sexual desire and arousal for a particular romantic interest, but they do not feel bonded to and have not yet committed to the romantic interest. That infatuation is derived mainly from passion is consistent with the characterization of infatuation as an immature kind of love that emerges early in a relationship, before any real intimacy or commitment has been achieved.

In contrast to Sternberg's model, other theoretical perspectives suggest that the complete experience of infatuation or passion does not emerge if sexual desire is the only active motivation.

Attachment theorists posit that the typical experience of passionate love results from the activation of both the sexual system and the attachment system. Although sexual desire frequently accompanies infatuation, as noted earlier, passion can emerge without sexual desire. For example, prepubescent children experience infatuations that evidence all of the adult features of passionate love, minus the sexual component. Attachment theorists propose that many features that are characteristic of infatuation, such as the desire for emotional closeness and concerns about reciprocation, stem from the activation of the attachment system. Just as infants wish to be physically and emotionally close to an attachment figure, infatuated romantic partners want to be physically and emotionally close to each other. Some recent empirical findings have suggested that the attachment system is an integral part of the passionate experience; manipulations designed to activate the attachment system (by triggering the experience of attachment anxiety) with respect to a particular romantic interest have the effect of boosting participants' passionate love for that romantic interest. Given the centrality of pair bonding as a mating strategy among humans, it makes evolutionary sense that initial romantic attraction would emerge at the intersection of the sexual system, which governs the reproductive act, and the attachment system, which bonds reproductive partners together for childrearing purposes.

Although attachment theory and the triangular theory have somewhat conflicting perspectives, there are explanations for the existence of infatuation that draw from both theories. In the early stages of romantic relationships, infatuation is pronounced, and romantic partners typically have not yet developed the intimacy and closeness that they later achieve as the relationship matures. At the same time, the *desire* to achieve a state of bondedness and intimacy may emerge early in a relationship. It is this desire for a bond with a particular partner that indicates the activation of the attachment system and is central to the experience of infatuation. If the sexual system (i.e., the passion component of the triangular theory) is activated without this desire for an emotional bond (i.e., desire for the intimacy component of the triangular theory), this will probably emerge as raw sexual attraction, not infatuation or passionate love per se.

Empirical and theoretical work that has explored the association between passion and intimacy also sheds light on the nature of infatuation. Some theorists have suggested that as romantic partners accumulate knowledge about one another, passion emerges as a result of such increases in intimacy. (In mathematical terms, passion is the first derivative of intimacy over time.) A wide array of research findings lends support to this hypothesis. For example, studies conducted by Arthur Aron and his colleagues have demonstrated that romantic partners experience an exhilarating expansion of the self as they become more intimate, and this self-expansion process generates greater feelings of romantic passion. As a second example, one study required opposite-sex strangers to stare into each other's eyes for 2 minutes—an intimacy-promoting activity. After the staring task, these strangers reported greater affection and passionate love for each other than did control participants who stared at each other's hands. Finally, research on individual differences has found that extraverts tend to disclose more (compared with introverts) about themselves and therefore quickly develop intimacy with potential romantic partners. Not surprisingly, then, extraverts also report greater passionate feelings on average. All of these findings support the idea that passion may emerge as intimacy increases.

Taken together, the theoretical perspectives reviewed earlier paint a coherent picture of the time course of infatuation. First, infatuation is most likely to emerge early in a romantic relationship, as intimacy is just beginning to increase. Soon thereafter, attachment theory predicts that infatuated individuals will start to desire more intimacy and want to feel bonded to the love object. In cases where both partners experience these feelings for each other, this will likely lead to a continued increase in intimacy, which in turn generates greater passion. As intimacy starts to reach an upper limit (once romantic partners have gotten to know one another extremely well), then passion is likely to decline.

Role of Arousal

Some of the best empirical work on the experience of infatuation has demonstrated the importance of physiological arousal in stimulating passion.

Berscheid and Walster's two-factor theory of romantic love predicts that passion is generated or intensified when people (1) are aroused physiologically, and (2) believe that another person is the cause of this arousal. The classic "love on a bridge" study is the most vivid demonstration of this point. In this study, male participants crossed either a frightening, narrow bridge or a wide, stable bridge and were greeted by an attractive female experimenter on the other side. Men who had just crossed the scary bridge (compared with men who had crossed the stable bridge) were more likely to call the experimenter in the ensuing days. In other words, as predicted by the Excitation Transfer Theory, the men misattributed the source of their physiological arousal: They believed it was the attractive female experimenter who caused them to feel excited, and they experienced greater attraction to her as a result.

Other experimental research has revealed similar results. For example, participants who were anticipating a shock or who just finished exercising reported greater attraction to an attractive romantic target than did control participants. In fact, the valence of the arousal seems to matter little because both positively (e.g., comedy) and negatively (e.g., horror) arousing material can increase passion for an attractive other. In the course of everyday life, the arousal that one believes to be caused by a potential romantic partner typically really is caused by that partner, and thus the romantic attraction that follows is the result of an appropriate attribution. Nevertheless, these experimental misattribution studies were essential to demonstrate the causal role that arousal plays in the passionate experience.

In summary, infatuation is a common experience in the opening stages of potential romantic relationships, one that frequently proves both exciting and terrifying. Infatuation has an important role in the psychological study of attraction as its features, time course, and theoretical underpinnings reveal much about the nature of human mating.

INFORMATION SEEKING

Researchers generally agree that individuals have a large appetite for information. Not surprisingly, that appetite is often fed by information about others with whom they have close relationships. This entry begins with a summary of the breadth of relational contexts in which information is sought, discusses predictors of the information-seeking process in close relationships, addresses biases that guide the search for information, discusses consequences of the decision to seek information, and ends with a technological development that is changing the landscape of information seeking in close relationships.

Contexts of Information Seeking in Close Relationships

Gaining knowledge about someone is a necessary component of initiating a relationship with him or

her. At the most basic level, individuals interested in developing a romantic relationship seek to discover whether there is a fit in attitudes and beliefs, and whether the person is available for, and interested in, such a relationship. Although there are many strategies that people use to discover whether someone is attracted to them, it is interesting to note that the most efficient form of information seeking in this case (e.g., “ask her or him if she or he liked me”) is also typically rated the least appropriate. That generally sums up the dilemma inherent to information seeking—be direct, but risk being inappropriate, or be indirect, but risk misunderstanding. Most studies show that individuals typically choose the latter. A whole host of other informational unknowns are tackled in this manner, among them the information exchange that contributes to sexual decisions. One would expect that a central feature of that exchange would be a sexual health discussion between partners. Yet considerable research suggests that such a discussion is relatively rare; if it does occur, it often comes *after* the first sexual encounter. Preliminary information about a partner’s sexual health seems to often come from assumptions about physical appearance or, curiously, from discussions with friends who are believed to know the partner’s past sexual history. This aversion to direct information seeking is also evident in that individuals often rely on “secret tests” of their partner to gain information about his or her level of commitment. For example, studies have shown that people sometimes choose to test their partner by acting in really negative ways (to see with how much they will “put up”) or by asking a friend to flirt with their partner and watching the partner’s reaction to the flirtation. These forms of indirect information seeking wane across a relationship’s life cycle. Yet indirectness remains a popular method of seeking information about a partner and reemerges as the primary method of gaining information during the dissolution and postdissolution phase of relationships, where inquiries about the partner’s motivations and behaviors are either avoided entirely or are tackled gently.

Of course, romantic relationships are not the only close relationships in which considerable information is sought. The parent–child relationship is another that involves its share of information-seeking decisions. Two periods in the life cycle of this relationship are especially prone to such episodes—when

children are in their adolescence and when parents are in or approaching old age. When children go through adolescence and young adulthood, they often engage in independence-seeking behaviors that place their parents in a precarious dilemma: seek information about suspicious behaviors and potentially violate their child’s privacy, or turn a blind eye and hope for the best? Although violating privacy brings with it distrust and the potential for further rebellion, ignoring signs of dangerous activity may end with disastrous consequences for the family. A somewhat similar spike in information-seeking decisions comes near the end of life, but this time it is the adult child who faces the dilemma. Seek information about the parent’s eldercare wishes and needs, or assume that she or he will reveal them when comfortable doing so? Unfortunately, studies suggest that people all too often choose the latter strategy and do not receive the information in time.

Predictors of Information Seeking in Close Relationships

The decision to seek information in close relationships or avoid doing so is a difficult one. As such, it is not surprising that several programs of research have tried to better understand the factors that predict the outcome of that decision. This literature can generally be separated into two approaches: one that focuses on features of the individuals’ personality and one that focuses on features of the situation.

Personality

Several scholars have shown that individuals differ in their desire for information. Suzanne Miller’s work on information seeking in health contexts has been able to separate people as either *monitors* (i.e., information seekers) or *blunters* (i.e., information avoiders) based on their responses to hypothetical scenarios. Similarly, Richard Sorrentino and his colleagues have shown that people differ on their orientation toward uncertainty and, by extension, information seeking in close relationships. Most recently, Bill Ickes and his colleagues have been able to show personality differences in the motivation to acquire relationship-threatening information. Other personality differences have been shown to have a less direct, but still important, association with

information-seeking decisions. For example, individuals' style of attachment, as well as their affinity for risky and novel situations, has been shown to influence the sort of information that individuals seek about their (potential) partner. Specifically, anxiously attached individuals seek information about partners that confirms their fears (i.e., partner shortcomings), and sensation seekers (those with affinity to risky and novel situations) pursue more information about potential partners than do risk-avoidant individuals. There is also evidence that self-esteem, along with the Big Five personality dimensions (Neuroticism, Extraversion, Openness to Experience, Competitiveness, and Conscientiousness) all impact information-seeking choices in a variety of ways.

Situation

Other approaches have focused on situationally specific conditions that impact individuals' information behavior in close relationships. Walid Afifi and colleagues' Theory of Motivated Information Management argues that individuals go through a three-phase process in deciding whether to seek information in interpersonal encounters. The first phase involves an assessment about whether their actual and desired levels of uncertainty about an issue match. If not, the theory argues that people first determine the costs and benefits of seeking information about the issue from a particular target (e.g., their romantic partner) and then decide whether they are able to effectively seek information about that issue from that person. A combination of those assessments then leads to a decision to either seek or avoid information. All these assessments are impacted by situational features such as mood, feedback from the target person, or target issue, among others. As a general rule, perceptions that the outcome will be positive and that one is able to effectively seek information leads to direct searches for information. The theory has been successfully applied to information-seeking decisions in both romantic relationships and parent-child pairs.

Information-Seeking Biases in Close Relationships

Although knowing whether someone will seek information is an important step to understanding the information-management process, it does not

deal with the biases that guide individuals' search for information. There is no doubt that individuals rarely, if ever, seek information in an objective manner. Instead, people's needs and motivations guide the sort of information that they gather and the way in which they interpret what they find. The research literature in this domain is vast. One motivational aspect that seems to play a strong role in the sort of information sought and its interpretation is the need for consistency. Decades of research has shown that individuals typically seek information that supports preexisting attitudes and beliefs. In relational contexts, this translates to a selective search for information that supports either preexisting or desired biases toward the person. For example, studies have shown the many ways in which people's positive impressions of their romantic partner allows them to overlook negative traits and glorify positive ones. In a similar vein, the research has revealed that people often look for information that supports preexisting hopes or fears.

Emotion is another biasing factor in the search for information. Individuals' mood strongly influences how much and what sort of information they seek, both generally and in relationships. Specifically, individuals in happy moods tend to seek more information, but focus on abstract-level information that is likely to maintain that mood. In contrast, those in sad moods take on a much more cautious approach to their information search and, within that selective approach, typically look for detailed information. It is also worth noting that emotions often combine with the bias toward consistency to influence the information sought. Moreover, neuroscientific studies have shown that different regions of the brain become activated during information-processing tasks depending on the emotion being experienced. So, not only does mood influence what information is sought, but how it is then processed and interpreted.

Consequences of Information Seeking

The general belief among both researchers and health practitioners is that information seeking is generally beneficial. After all, it seems better to make an informed decision than an uninformed one. But is it? In all likelihood, it is. However,

growing evidence suggests that information seeking sometimes leads to worse outcomes (at least in the short run) than information avoidance. For example, research that has compared health outcomes for monitors and blunders has consistently shown that monitors (i.e., information seekers) do more poorly on health measures than do blunders (i.e., information avoiders)—they report greater depression, visit physicians more often, are more anxious, and improve less rapidly following medical procedures. In a related vein, Sorrentino and colleagues' work on uncertainty orientation has shown that avid information seekers generally report lower relational trust and satisfaction than information avoiders. Finally, information seeking has the potential to lead individuals toward poor decisions. For instance, one study showed that college students were woefully misinformed about whether their sexual partner had a sexually transmitted infection (STI), but were *certain* about the accuracy of their information. Why? Because that certainty was reached through considerable information seeking. The result may be that information seekers are less likely to practice safe sex and be more susceptible to STIs than information avoiders. The latter group may be more cautious in their approach to safe-sex decisions precisely because they do not have the false security gained by those who sought information. This is one area of research that is sorely in need of additional attention.

Impact of Social Networking Sites

The spread of online social networking sites has important implications for information seeking in close relationships. In the past 3 to 4 years, sites such as *Facebook* and *MySpace* have become online hosts to millions of individual profiles across the globe and a rich source of information for those seeking it. Indeed, recent studies have shown that individuals' primary use of these sites is to gather information about people who they have recently met. The effort is made easy by the fact that people often leave their profiles open to the public, with information ranging from contact information to likes and dislikes to photographs, and well beyond. Unfortunately, the scholarship in this area has not kept pace with the speed in which this phenomenon has spread. This new mode of

information seeking in close relationships, however, has significant potential to dramatically change both what information is discovered and the way in which it is done.

INGRATIATION

Ingratiation is a form of self-presentation or impression management, with the specific goal of enhancing one's likability. Any behavior that potentially

has the effect of increasing liking for the actor and that is enacted for this reason can be seen as an instance of ingratiation. This does not mean that all likable behaviors are examples of ingratiation; the crucial point is the motive for the behavior. For example, if an employee supports his or her boss in a meeting because the employee agrees with the boss, or if someone helps a friend for truly altruistic reasons, the behavior is not ingratiating. Of course, the boundary is quite fuzzy because people are not always aware of their true motives. They may consciously think they really agree or wish to be genuinely altruistic, whereas their unconscious motives may be ingratiating. Many instances of ingratiation are unconscious, so ingratiation occurs more often than people generally assume. This entry discusses the different strategies that ingratiators use and the motives and goals that ingratiation can serve.

Ingratiation Strategies

Different research paradigms have been used to study how people ingratiate themselves and what the effects are. When looking at the ingratiator's part, the researcher may instruct participants interacting with someone to make the other person like them and then examine how they behave. Looking at the target's end—the person being ingratiated—the researcher can expose participants to an ingratiating actor and examine whether they like this person or are easily influenced by him or her, compared with control conditions (e.g., a noningratiating actor or participants observing the same behavioral episode directed at someone else).

On the part of the actor, studies show that getting people to like oneself (ingratiation) is easier than getting them to think that one is smart and capable (self-promotion, another form of self-presentation). A common ingratiation strategy is to show interest, ask questions, pay attention, and single out the other person to make him or her feel special. A second strategy is to do favors, buy presents, or to help or assist a person. Third, people may show support and loyalty (e.g., support their supervisor during a meeting). A fourth way to be liked is simply to smile and be friendly, cheerful, and positive. Fifth, people can directly express

admiration by flattering people and telling them what they like or admire about them. Sixth, people can create sympathy by talking about things they have in common with someone or expressing agreement in attitudes, values, or interests because similarity produces attraction.

On the part of the target, ingratiation is not always recognized. Uninvolved observers tend to quickly notice when ingratiation occurs, whereas targets of ingratiation are less suspicious. Thus, the behavior is generally quite effective precisely with respect to the person for whom it is intended, the target. So, when a student flatters a teacher or offers assistance, fellow students who see this may immediately suspect the student's motives, but the teacher may simply appreciate the help or the excellent judgment of character and like the student as a result. Similarly, in a dating context, people can get away with quite blatant flattery unless it becomes unequivocally clear that they make the exact same compliments to other potential dating candidates.

One reason that targets may be relatively gullible is that most people aim to have a positive view of themselves (called the self-enhancement motive), and when they are ingratiated, their self-esteem is bolstered. This makes them feel good even if they might not entirely trust the ingratiator's motives. Importantly, there is a difference between cognitive and affective responses to ingratiation. Cognitively, the target may suspect someone's motives, especially if the flattery concerns qualities that the target is not sure she or he has. Affectively, however, it feels good to be the object of interest, compliments, and support. Many people say that they do not care for this, but unconsciously all people like to feel good about themselves, and they feel good most of all when they feel valued by others. This is a central tenet of Mark Leary's Sociometer Theory.

As a consequence, ingratiation can be a powerful tool in social influence. In his seminal book on ingratiation, Edward Jones noted that the goal of ingratiation is typically instrumental: People ingratiate others because they want to influence their behavior in some way (e.g., get a date, borrow money, get a raise, get a good grade). Thus, ingratiation is a strategy for social influence and it is, in fact, used quite a lot by sales people. People buy more from someone who flatters them. For

instance, if a sales person compliments a shopper on his or her figure and excellent taste in clothes, the shopper is more likely to buy the shirt. In part, this happens because people like the person who ingratiate them. Also, being ingratiated enhances their mood, which in turn may affect their behavior in desired ways. Another reason that ingratiation works is the reciprocity principle: If someone does something good for you, you want to do something in return.

So, the effects of ingratiation are generally as intended: The target likes the ingratiator and is more inclined to do favors to the ingratiator. The ingratiator may not be aware of his or her own insincerity and may come away feeling that she or he and the target get along well. Jones called this the *autistic conspiracy*: Both ingratiator and target are not fully aware of the hidden agenda in their interaction (the ingratiator who wants something, the target who is happy to be flattered) and simply feel good because they both attain something desired. Neither person is motivated to look at the interaction more critically.

Motives Underlying Ingratiation

A strong motive for ingratiation, then, is simply that people can affect others' behavior with it. But there are other motives as well. For one, ingratiation is the lubricating oil of social traffic. If a waiter asks about a meal or if a friend has a new hairdo, most people will say something nice even if they don't entirely mean it. Saying exactly what one thinks can make people feel awkward and uncomfortable. A related motive for ingratiation is that people who get along well with others will be liked and responded to favorably, which in turn benefits their self-esteem. In effect, then, ingratiation can be seen as a social skill.

As noted, targets of ingratiation typically like the ingratiator. Observers are in a different position, and they may give quite harsh judgments of ingratiators. The strongest cue for detecting ingratiation is dependence: When a person is likable toward someone with higher status or power, people instantly become suspicious of ulterior motives. At this point, their judgments are not yet quite negative because they cannot be certain: For all they know, the person might simply be likable. But

once they notice that a person behaves less friendly toward those with less power, they immediately identify the person as a brownnoser and judge the person negatively—in fact, just as negatively as someone who is dislikable toward everybody. This is called the “Slime Effect” because it was first reported in the Netherlands, where people are more wary of ingratiation than in the United States and where the common word for ingratiation is *slime*.

Ingratiation and ulterior motives are identified more easily when the ingratiator depends on the target in some way. This can occur in hierarchical relationships in organizations, but in many other settings as well (e.g., when the ingratiator is a single man out to find a date and the target is a beautiful woman, when the ingratiator is a child or adolescent and the target is a parent or teacher, or when the target is a powerful person in a company or in politics). Because such asymmetry in power makes it more likely that friendly behavior by the lower status person is seen as ingratiating, this presents the ingratiator with a dilemma: When it matters most (i.e., when one depends strongly on someone), ingratiation is most likely to backfire because people will easily see through the ingratiator's hidden agenda, so that credibility is strongly reduced. This problem is called the ingratiator's dilemma.

Conversely, it is relatively easy for powerful people to ingratiate lower status persons without being suspected of insincerity, but the incentives for doing so are also smaller because high-status persons usually do not need favors from those with less power. This dependence is likely underestimated by lower status persons because ingratiation is less easily noticed in these cases. Ingratiation by powerful people may actually be more common than is often assumed.

Fortunately for the low-status ingratiator, several psychological mechanisms may come to the rescue. People in powerful positions typically do not see how their subordinates behave toward others, so the slimy subordinate may easily get away with it. Leaders in organizations usually have multiple subordinates to whom they must attend, so they do not keep track of how everyone behaves toward everyone else. Also, leaders are typically high in self-esteem, so excessive flattery may simply confirm what they already know, and they are not likely to question the ingratiator's motives. Moreover, people

generally attach more weight to how a person behaves toward them than toward others, another reason that flattery toward powerful people will usually have the intended effect. As a result, powerful people rarely find out what others really think of them and may end up with a rather inflated and unrealistically favorable image of themselves.

In addition, according to Jones, ingratiation can use several strategies to resolve the ingratiation's dilemma—that is, to make themselves more credible when flattering someone on whom they depend. The first is to build a power bank by starting the flattery long before a favor is needed. By ingratiating oneself for a longer period, one builds up credit, which can later be withdrawn.

A second strategy is to find a setting in which the power imbalance is less salient. For instance, subordinates may take their supervisor out for dinner, thus creating a setting in which it is less obvious who is in charge and who is not.

Third, people sometimes obscure their behavior—for instance, by disagreeing with their supervisor on trivial matters. This way they won't look as if they blindly follow and support their supervisor, and they convey the impression that they are independent.

Finally, it is a good idea to flatter via a third party. For example, one may tell the boss's secretary that one has never had a better supervisor than this one. With a little luck, the secretary will pass the compliment on to the boss, and the flatterer will have a great deal of impact because the flatterer is not suspected of ulterior motives.

The examples used here are prototypical instances of ingratiation, in which the ingratiation is not sincere. It is important to realize that, in everyday life, there is a large fuzzy area between not saying exactly what one thinks and blatantly deceiving people to accomplish one's goals. In everyday social interaction, ingratiation has many advantages. Most people do not know the truth of what others really think of them, and they might be a lot less happy if they did. This creates the window of opportunity in which ingratiation is effective.

INITIATION OF RELATIONSHIPS

Relationships go through many stages of development, but the first stage is always initiation. Although people (and scientists) do not usually refer to an initiation stage for family relationships, this stage is particularly relevant for voluntary relationships, such as romantic relationships and friendships. People select their friends and lovers, and therefore such relationships need to be initiated in order to exist. This entry summarizes several important aspects of the initiation stage of relationships, including the meaning of relationship initiation; how common relationship initiation is; diverse settings in which relationship initiation may occur; involvement of the social network in relationship initiation; the emotions, beliefs, and behaviors associated with relationship initiation; and the negative side to relationship initiation.

What Does Relationship Initiation Look Like?

Generally, relationship initiation refers to the beginning period of relationship development for voluntary relationships such as romantic relationships and friendships. Some theorists, such as George Levinger and Mark Knapp, have developed stage models of relationship development and argue that the first stage of the relationship includes such phases as first awareness of each other, first superficial contact, and the first communication behaviors, which express that the two are developing a connection or potential for a relationship. The relationship initiation stage is probably more distinct as well as more clearly

recalled later for those whose relationships blossom quickly. For example, consider one hypothetical couple: Abby and Alex meet in a bar, e-mail and phone for a week after this brief meeting, and then begin dating. For them, first awareness, first superficial contact, and first communication of a connection occurred quickly and without too much time between each phase. Another hypothetical couple, Kate and Samuel, were in a class together their freshman year in college and talked occasionally, but then forgot about each other until they frequented the same coffee shop their senior year. It was months of running into each other at the coffee shop and chatting briefly before they realized their attraction for each other; another month passed before one suggested to the other that they should go to dinner. When was their relationship initiated? Months and even years spanned between their first awareness, first superficial contact, and the early communicative behaviors that expressed a desire to begin a relationship. Relationship initiation refers not only to the first time two people meet, but can also refer to the process of the relationship transitioning from one type of relationship (casual friendship) to another type (romantic). Laypeople, as well as experts on relationships, would likely consider the time period in which a pair transitions from casual acquaintances to dating partners as the initiation of the relationship.

In defining relationship initiation, Dan Perlman distinguished between “initiating interactions” and “initiating relationships.” As he notes, “initiating interactions” may lead to a relationship, but in many cases may fail to do so. Many pairs experience attraction for each other and initiate interactions that never develop into a relationship. More research is needed to explore why some initiating interactions lead to a relationship and others do not.

How Common Is Relationship Initiation?

Compared with the time that people spend maintaining and nurturing their existing relationships (including family relationships), the time spent engaged in relationship initiation is relatively brief. Because there is a norm of exclusivity and monogamy associated with romantic relationships, most adults have only one such relationship

at a time. Therefore, people who stay in a romantic relationship for a long period generally do not enter the initiation stage of a romantic relationship again unless their long-term romantic relationship comes to an end, either through dissolution or death of the other. Adolescence and young adulthood, however, is a time of experimentation with short-lived romantic relationships, and therefore relationship initiation behaviors are quite common at that time.

In contrast to the limited number of romantic relationships that may develop over a lifetime, friendships may begin at any time regardless of how many friends one already has. Friendship generally has a less clearly defined initiation stage compared with romantic relationships. Two people may move slowly from nodding acquaintances to casual acquaintances to good friends, and possibly on to best friends. Friendship initiation may be more common when there are life transitions or changes, such as in geographical location, job, or marital status. The number of new friendships that are initiated is also influenced by the desire for and capacity (e.g., resources) to have a large social network. Some people prefer to have many friends and are often expanding their social network (although perhaps at the same time allowing friendships at the periphery of their social network to fade away). Others may prefer only a few close friends.

Socioemotional Selectivity Theory, developed by Laura Carstensen, states that the desire to initiate new friendships varies across the life course. This theory argues that as people approach the end of their life, they become more selective in regard to with whom they spend time. When time is running out, resources (including time) are devoted to intimate others, rather than to developing new relationships. At younger ages, however, when focusing on the future and when new contacts are important, relationship initiation is likely to be much more common.

Where Does Relationship Initiation Occur?

There are a variety of settings in which relationships begin, including bars, classes, work, parties, church, and on the Internet. Although the most common settings for meeting potential partners vary somewhat as a function of age, according to

several studies, the most common locations for meeting romantic partners are parties, classes or work, and settings centered around hobbies or sports. Many years ago, social psychologist Bernard Murstein distinguished among settings in which people meet others by the degree to which they involve different degrees of voluntariness of interaction. A *closed field* (e.g., a small college seminar) is characterized by the presence of a small group of people who are all likely to interact with one another. In contrast, in an *open field* (e.g., a singles bar), there is no structured interaction and therefore more choice about one's interactions. Some have speculated that the factors that lead to attraction and the desire to initiate relationships differ in these two types of settings. For example, physically attractive people are more likely to be noticed in an open-field setting. In closed fields, however, attraction to others can be influenced by less superficial characteristics, such as the person's honesty, integrity, or sense of humor.

Regardless of the particular setting in which two people meet, one of the major predictors of the likelihood of two people initiating a relationship is physical proximity. Physical proximity increases the likelihood that two people will be in the same setting at the same time. Furthermore, within a particular setting (e.g., an apartment, a classroom, a workplace), two people are more likely to initiate interaction the closer in proximity they are. Proximity contributes to the initiation of a relationship for a number of reasons, including the high rewards and low costs associated with interacting with someone who is near (relative to those who are at a distance) and the familiarity that derives from "mere exposure" to the other (such as seeing that person in class repeatedly). Another type of proximity, social proximity, also influences the likelihood of two people initiating a relationship. As noted by Malcolm Parks and other experts of social networks, the closer two people are in a network of relationships (e.g., if they have mutual friends), the greater their likelihood of meeting.

Advances in communication technologies have reduced at least somewhat the importance of physical proximity for initiating interaction with others. Although there has been considerable media attention given to online relationship initiation, recent studies with representative samples

indicate that only a small proportion of committed, romantic relationships began online (3 percent according to one study, 6 percent according to another). Nonetheless, this translates to millions of relationships, and most experts agree that online relationship initiation is here to stay and is likely to become more common.

Although online dating is generally a homogeneous concept to the general public, differences exist among types of Internet relationship initiation. Katelyn McKenna, a pioneer in the study of relationship initiation on the Internet, has distinguished among three types of online relationship initiation: *naturally forming relationships*, *networked relationships*, and *targeted relationships*. Naturally forming relationships occur in those venues in which people congregate online because of an interest or hobby. For example, although the goal for participating in newsgroups and interactive online games is not relational, relationships can form from interaction on these sites. Networked relationships may also be initiated online through social network sites such as *Facebook*, *Friendster*, and *MySpace*. These social network sites provide opportunities to meet others who are linked to one's friends and acquaintances.

Targeted relationships are those that develop from interactions in online dating sites. People go to dating Web sites (e.g., *eHarmony*) for the specific purpose of initiating a romantic relationship with a compatible match. Such sites can facilitate relationship initiation by offering a large pool of potential partners, an easy way to search for compatible others who are interested in starting a relationship, and a legitimate and relatively safe format for initiating communication, such as by sending anonymous preprogrammed messages. Individuals meeting on the Internet often disclose personal information sooner and deeper than they might in face-to-face conversation.

Long before the Internet, there were newspaper personal want ads, video-dating services, singles functions, and professional matchmakers. These services, along with Internet dating sites, have been described as *commercial marriage market intermediaries*. Another recent type of commercial service to assist in relationship initiation is speed-dating. These are events that often occur in bars and involve brief "dates," 3 to 8 minutes long, for participants who attend for the purpose of meeting a date.

Self-Initiation Versus a Little Help From Friends and Family

The first meeting or superficial contact between two people is a big step in the relationship initiation process and is sometimes planned and schemed even if only in the minutes after first awareness of the other. According to research on dating relationships conducted by Charles Berger, people use any of three general techniques to meet another person, particularly in open fields. One way is to introduce oneself to the other. A second technique is to give nonverbal cues and wait for the other to introduce him or herself. Third, one could have a mutual friend make the introduction. Berger found that men were more likely to engage in the first strategy, whereas women were more likely to engage in the other two strategies.

The strategy of friends facilitating the initiation of relationships is common. Many relationships begin through an introduction by a friend or through other types of assistances from the social network. Research conducted with college students and with national, representative, samples of adults indicates that 25 to 50 percent of people meet their current partner through another person. Most often this is a friend, but family members, coworkers, and others also make introductions. Besides assisting in first meetings, friends and family members contribute to the relationship initiation process through supportive behaviors, such as inviting the two to social gatherings and encouraging the relationship. Research indicates that these supportive behaviors from the social network have a positive effect on the likelihood that the relationship develops.

In some cultures, traditionally, parents were instrumental in orchestrating the relationship initiation process through arranged marriages. This still occurs in some areas of the world, such as in subcultures in India.

Emotions, Beliefs, and Behaviors Associated With Relationship Initiation

Regardless of the type of relationship, the setting in which the relationship begins, relationship initiation consists of many specific emotions, behaviors, and beliefs.

Attraction

Attraction is the emotion or catalyst behind relationship initiation in most voluntary relationships. People initiate relationships with others because they are attracted to them. Considerable research beginning in the 1960s examined the factors that lead to attraction. These include proximity, perceived similarity, reciprocity of liking, and the degree to which the other person is physically attractive. In addition, a host of other desirable characteristics—including wealth, status, sense of humor, and warmth/kindness—can lead to attraction primarily by increasing the perceived probability of having rewarding experiences. Although people may be attracted to those who have desirable characteristics, in real life, matching often occurs by the pairing of individuals with equally desirable characteristics.

Behaviors to Demonstrate Interest

In open fields (such as single functions), people can send nonverbal signals to show their interest in developing a relationship, which can have a significant impact on the likelihood that other(s) will return relationship-initiating-type behaviors. Observational studies of men and women flirting in singles bars suggest that successful flirtation involves one person approaching the other. In a unique observational study, Monica Moore recorded the nonverbal acts that women engage in that seemed to result in a man's attention within a few seconds after the behavior. Some of the more common flirting behaviors were the smile, laugh, room-encompassing glance, short darting glance, head nod, primp, lean, and solitary dance. In follow-up research, she found that the average number of flirting acts engaged in by women was much greater in singles bars than in other settings, such as a snack bar or library, suggesting that women strategically use flirting behaviors in settings in which the behaviors may have an effect on attraction. Of course, heterosexual men (and homosexual men and women) are likely to do the same, but the focus of the research has been on women as flirts and men as onlookers.

The first communication in an open setting is often called "the opening line." Three types of opening lines have been identified: *direct* (a direct statement of interest), *innocuous* (a pleasant statement, such as

about the setting), and *cute-flippant* (humor, often with sexual overtones). Although all three types of opening lines may be used in the get-acquainted process, cute-flippant lines (e.g., “Your place or mine?”) are rated as least desirable, especially by women.

Beliefs

There are various beliefs that can influence the relationship-initiation process, for example, by influencing the information to which a person attends and how that information is processed. Some general schemas and beliefs that people bring to a relationship come from the larger culture, including the family, peer group, and the media. Romanticism (or romantic attitudes) is a general focus on relationships that emphasizes love as a basis for entering a relationship. People who have strong romantic beliefs are likely to approach relationship initiation in different ways than those who endorse romantic beliefs to a lesser degree. For example, in a study by Sandra Metts, a belief in love at first sight was associated positively with commitment to one’s partner following first intercourse. In addition, greater romanticism was associated with recalling that one was more in love sooner in the relationship. Another example of a general belief that influences relationship initiation is relational ideals, which are beliefs about what makes a good relationship and an ideal partner. For example, a person may believe humor is important in an ideal partner, and therefore may be drawn to partners who make them laugh. These relational ideals will influence the type of partner sought and how one approaches a potential relationship.

People also develop specific beliefs about the person or the relationship, which can influence the initiation process. First impressions can be based on the other’s appearance, demographic characteristics (e.g., age), and their initial communication. These first impressions can, in turn, influence behavior toward the other, which may create a self-fulfilling prophecy. That is, the other can become more like the person we think they are based on our first impressions.

The Negative Side of Relationship Initiation

If a person desires to enter a new romantic relationship or a friendship, has the requisite social

skills to engage in relationship initiating behaviors, and the other person is also interested and responds with his or her own initiating behaviors, the result can be an exciting and positive event. The successful start to a new relationship is associated with enhanced positive mood and self-esteem. However, the initiation stage of relationships, as is true of all stages of relationships, also has a dark side. Even in the most successful initiation attempts, there are times of awkwardness, embarrassment, and miscommunication.

Beyond the typical awkwardness of two strangers meeting for the first time, interest in developing a relationship is not always mutual. Although the disinterested partner may be flattered, he or she is likely to reject the attempt to initiate the relationship. Rejection, even mild rejection, feels bad and has potentially important emotional consequences. The person being sought may, in some cases, be exposed to unwanted and unrelenting relationship pursuit, such as stalking in extreme cases. The person who does not want the relationship, who is the victim of unwanted relational pursuit, can experience anger, guilt, and perhaps some fear.

Another negative experience of relationship initiation occurs when a person desires to enter a relationship, but fails to do so because of fear of rejection, social anxiety, or a lack of social skills (i.e., not knowing how to communicate with the potential target). People who have an insecure attachment style find it more difficult to initiate and maintain close relationships. Another negative experience is loneliness, which is a discrepancy between the number of relationships one initiates and maintains and the number that is desired.

In summary, the initiation stage is an essential stage of the voluntary relationship. It has been a relatively neglected topic of study in the field of personal relationships. The *how*, *where*, and *when* are equally important as the *who* is when it comes to relationship initiation. The manner and the setting in which an initiation takes place often influences the relationship’s potential to prosper.

IN-LAWS, RELATIONSHIPS WITH

When one marries, the new partner becomes an “in-law” to all family members related to his or her spouse. The marriage ceremony creates a family out of relative strangers. No other family relationship has generated so much negative attention. The first mother-in-law joke was recorded in Roman times. In-law relationships, especially those related to the mother-in-law, have led to the creation of “mother-in-law” languages and taboos. Many entering the in-law domain still do so with negative expectations and anxiety about these new family relationships. This entry explores the

nature of in-law relationships, their psychological dynamics, and research findings.

Nature of In-Law Relationships

The term *in-laws* often conjures images of an intergenerational family represented by mothers-in-law, daughters-in-law, fathers-in-law, and sons-in-law. Most commonly, one thinks of the mother-in-law–daughter-in-law or son-in-law relationship when reflecting on in-laws. However, the in-law network also extends to fathers, siblings, cousins, aunts, uncles, and grandparents.

Changes in family life, such as divorce and remarriage, have increased the convolution of these connections. For example, divorce and remarriage increase the number of mothers-in-law or fathers-in-law in a marriage network. The wife of a man whose parents have both divorced and remarried might have two or more mothers-in-law. A remarried woman with children likely retains her relationship with her previous mother-in-law, for a potential total of three or more mothers-in-law.

Although expectations are common, especially ones that suggest intrusiveness and negativity, there are few established norms for in-law roles. The extended family models once prevalent in an agrarian society have vanished in a more mobile, egalitarian society. Women in the workforce, geographic separation, and later ages at marriage have increased the complexity of in-law relations. The increasing independence and cultural diversity of marriage partners leads them to establish isolated nuclear families with fewer face-to-face connections with the extended family network.

Psychological Dimensions

In-law relationships are perhaps the most complicated in the family system. This relationship is a secondary rather than a primary relationship created through the choice of one family member. Due to their intergenerational nature, in-law relations are influenced by differences in developmental stages and generational differences.

In-law relationships are transformed across time by others in the family network. For example, the openness and vulnerability of a daughter-in-law's

relationship with her mother-in-law is often related to the nature of her relationship with her own mother. On the one hand, if she has a close tie with her own mother, she might view a mother-in-law who is different or expresses different values from her own mother as not fitting within her family, despite the fact that she is her husband's mother. On the other hand, a daughter-in-law who has a distant, formal relationship with her mother may appreciate her mother-in-law's hugs and expressions of affection as providing a sense of connection she has missed with her own mother. How the husband describes and expresses his feelings about his mother, both pre- and postmarriage, can influence his wife's perception of her mother-in-law. The birth of a child/grandchild also changes the dynamics because the two women now have a mutual focus they can celebrate together.

Power and control are persistent issues among in-law relations. While remaining asymmetrical, in-law interactions face constant power shifts across time. At the beginning, when the child-in-law-to-be is first introduced, most of the power resides with the parents-in-law. Once the wedding occurs, the power differential shifts to give the child-in-law more power. Once a child is born, the child-in-law, specifically the daughter-in-law, holds the majority of the power. She becomes the gatekeeper controlling access to her parents-in-law's grandchildren.

Although both research and popular culture focus on the mother-in-law–daughter-in-law or son-in-law relationships, the interactions of siblings-in-law and fathers-in-law also play an important role in family functioning. For example, research indicates that, among rural farm families, fathers-in-law can create more strain on young marriages than any other in-law relationship. At times of family or health crises, parents- and children-in-law often receive the support they need to survive the crisis from their in-laws. Female in-laws might provide the emotional support that male kin struggle to adequately provide. A sister-in-law who views her brother's wife as the sister she never had can influence her mother's perception of her brother's wife, positively impacting that relationship's quality. Likewise, a hostile relationship with a father-in-law might contribute to negative perceptions by the mother-in-law of her daughter's husband. The ambiguity experienced by both generations about

what the relationship “should be” increases the fragility of in-law relationships.

The rules for appropriate interactions become more ambiguous as the number of generations increases. The ambivalence often found in adult parent–child relationships is intensified in the parent-in-law–child-in-law relationship. One of the most ambiguous roles in the extended family network is that of the father-in-law. For example, the matriarchal nature of the African-American family contributes to a sense of ambiguity for the father-in-law as to how he should act in his role in the family. Ambivalence can add stress that weakens the kinship network.

Research on In-Law Relations

Due to the multifaceted, dynamic nature of in-law relationships, little research has explored them. Most of the research focuses on women's roles in the extended family and the role of children-in-law in caring for aging parents-in-law. Within the family network, women fulfill the role of kinkeepers. They are expected to maintain the connections, rituals, traditions, and histories for both sides of the family.

Intergenerational exchanges occur across the family life cycle. In the early years of family life, support often originates from the older generation and passes to the younger (i.e., providing child care, financial assistance, and advice). As the parents age, they depend on younger family members to provide the support needed to remain independent. Research suggests that, in the absence of a spouse or daughter, the responsibility for caring for aging parents falls to the son(s). Typically, the son provides instrumental care, like home repair. When personal care is needed, sons depend on their wives to assist with bathing, feeding, and so on. When the primary caregiver is a daughter, her husband, the son-in-law, often assists by providing instrumental care. Thus, the daughter-in-law and son-in-law are central in the caregiving network supporting parents-in-law. The only factor consistently found to be related to children-in-law's willingness to provide assistance is the strength of the emotional tie between the son- or daughter-in-law and the parent-in-law. Yet the complexity of in-law relationships, the in-law's lack of choice in

selecting this family member, and the impact of other individuals on relationship quality combine to make building positive in-law relationships challenging.

In-law relationships are a central core of extended family relationships. The impact of each generation on the other continues throughout the family life cycle. The dynamic nature of these relationships provides the opportunity for the best of relationships or the worst of relationships. The dynamic interaction across multiple generations opens the opportunity for building unique family relationships like no other in the kinship network.

INSIGHT-ORIENTED COUPLE THERAPY

Insight-oriented couple therapy (IOCT) emphasizes the interpretation of recurrent maladaptive relationship patterns from a developmental perspective. IOCT helps partners develop more satisfying ways of interacting by coming to understand and modify enduring dysfunctional patterns of emotional and behavioral responses linked to

unmet needs and unresolved anxieties rooted in prior relationships. This entry describes the historical and theoretical underpinnings of IOCT, the sequence of interventions through which partners gain a new understanding of dysfunctional relationship themes and modify maladaptive interpersonal exchanges, and empirical findings regarding this treatment approach.

Historical and Theoretical Underpinnings

Insight-oriented approaches to couple therapy vary in the extent to which they emphasize the unconscious nature of relational patterns, the developmental period during which these maladaptive patterns are acquired, and the extent to which interpersonal anxieties derive from frustration of innate drives. However, a shared focus of insight-oriented strategies are previous relationship injuries resulting in sustained interpersonal vulnerabilities and related defensive strategies interfering with emotional intimacy, many of which operate beyond partners' conscious awareness. Consequently, insight-oriented approaches to couple therapy emphasize that partners' maladaptive relationship patterns are likely to continue until they are understood in a developmental context. This new understanding serves to reduce partners' exaggerated emotional and behavioral reactivity and permits them to develop alternative, healthier relationship patterns.

Couple interventions emphasizing the interpretation of maladaptive relationship themes derive from diverse theoretical approaches that can be placed on a continuum from traditional psychoanalytic techniques rooted primarily in object relations theory to schema-based interventions derived from more traditional cognitive theory. In its most orthodox formulation, IOCT derives from object relations theory (developed by Melanie Klein, Ronald Fairbairn, and others) and its central tenet that the primary drive in infants is to secure attachment to the mother. From interactions primarily with the mother, infants develop internalized images (or "introjects") of the self, significant others, and transactions connecting these images. From an object relations perspective, maladaptive relationship patterns of adults reflect enduring, unhealthy introjects that give rise to inevitable frustration when these are projected onto

relationships with significant others. In a distressed marriage, partners' dysfunctional mental representations of significant others interact in an unconscious, complementary manner, resulting in repeated disappointments and persistent conflict. Consequently, the goal of psychoanalytically oriented couple therapy is helping partners to modify each other's projections, distinguish these from objective aspects of their own self, and assume ownership of their own projections.

Evolving from object relations theory, attachment theory (developed by John Bowlby) emphasizes the importance of emotional closeness to others as an innate survival function from which infants develop information-processing capabilities and emotional responses intended to foster secure emotional bonds. From an attachment perspective, difficulties in intimate adult relationships stem from underlying insecure or anxious models of attachment. Susan Johnson and Leslie Greenberg developed emotionally focused couple therapy (EFT) from an attachment theory perspective. EFT is different; EFT is how this is known by the field.

Interpersonal role theory (developed by Jack Anchin and Donald Kiesler) regards the persistence of maladaptive interpersonal patterns as resulting from their reinforcement by the responses of significant others. Rather than stressing dysfunctional mental representations, interpersonal theory emphasizes the unconscious assignment of specific roles to oneself and others in which feared relational events are elicited and enacted by the individual in his or her interactions with others.

Schema theory (developed by Mardi Jon Horowitz and expanded by Jeffrey Young) emphasizes relationship schemas extending beyond attachment to the mother (object relations theory) or significant others (attachment theory) to consider more generally how early relationship experiences influence adult intimate relationships. Schema-based approaches to couple therapy overlap with IOCT in their emphasis on interpretation of interpersonal exchanges within the therapy session as a vehicle for change, attention to affect during the processing of schema-related events, and their emphasis on the childhood origins of maladaptive schemas and the emotional reworking of these early experiences.

Drawing on earlier psychodynamic formulations, Douglas Snyder and colleagues described an

insight-oriented approach to couple therapy emphasizing affective reconstruction of previous relationship injuries. In affective reconstruction, developmental origins of interpersonal themes and their expression in a couple's relationship are explored using techniques roughly akin to traditional interpretive strategies promoting insight, but emphasizing interpersonal schemas and relationship dispositions rather than instinctual impulses or drive derivatives. Previous relationships, their affective components, and strategies for emotional gratification and anxiety containment are identified to highlight each partner's consistencies in their interpersonal conflicts and coping styles across relationships. In addition, ways in which previous coping strategies represent distortions or inappropriate solutions for emotional intimacy and satisfaction in the current relationship are articulated.

Treatment Components

Understanding of maladaptive relationship patterns begins with identifying exaggerated emotional responses to current situations—for example, intense hurt or anger in response to modest disapproval from one's partner. Both partners are encouraged to explore early relationship experiences that evoked similar feelings and to consider how these emotional responses may have originally developed as protective coping strategies or tactics for satisfying interpersonal needs.

Initially, previous relationships are explored without explicit linkage to current relational difficulties to reduce anxiety and resistance during this exploration phase. Both partners are encouraged to remain "intently curious" about their own and each other's relational history. Gradually, as the couple continues to explore tensions and unsatisfying patterns in their own relationship, both partners are encouraged to examine ways in which exaggerated emotional responses to current situations have at least partial basis in affective dispositions and related coping styles acquired in earlier relationships. Developing a shared formulation of core relationship themes is vital before linking these themes to current relationship exchanges. Both individuals can be helped to understand that, whereas certain relational coping strategies may

have been adaptive or even essential in previous relationships, the same interpersonal strategies interfere with emotional intimacy and satisfaction in the present relationship.

In IOCT, the therapist's direct access to exchanges between partners affords a unique opportunity for linking enduring relationship themes to current relationship events. Rather than interpreting exaggerated responses that distort exchanges between the partner and the therapist, the focus is on partners' exchanges in the immediate moment. Interpretations emphasize linking each partner's exaggerated affect and maladaptive responses to his or her own relationship history, emphasizing the repetition of relationship patterns and their maintaining factors in the present context. In linking the couple's current struggles to enduring relationship patterns, the therapist encourages attention to the following questions: How does the immediate conflict between partners relate to core relationship themes explored earlier in the therapy? What are each person's feelings toward the other and their desired response? What impact do they wish to have on the other in this moment? How do their perceptions regarding their partner's inner experience relate to their attitudes toward themselves? What fantasies do they have regarding their partner's possible responses? What kinds of responses from their partner would they anticipate being helpful in modifying their core beliefs about their partner, themselves, and this relationship?

In IOCT, cognitive linkage of relational themes from early development to the current context is frequently insufficient for reconstructing or modifying these interpersonal patterns. The affective component of interpretation is seen in the reconstruction of these critical emotional experiences in the immediate context; new understanding by both partners often promotes more empathic responses toward themselves and each other, facilitating more satisfactory resolutions to conflict. Often the individuals must be encouraged to work through previous relationship injuries (e.g., with parents or intimate partners), grieving losses and unmet needs, expressing ambivalence or anger, and acquiring increased differentiation of prior relationships from the present one.

Partners' insight into enduring maladaptive relationship themes makes possible but does not inevitably

lead to changes in their own relationship. In addition to interpretive strategies, IOCT promotes interactions that counteract early maladaptive schemas. Thus, the couple therapist allows partners' maladaptive patterns to be enacted within limits, but then assists both partners in examining exaggerated emotions in their present exchange. Partners' exaggerated responses are framed as acquired coping strategies that interfere with higher relationship values such as intimacy, trust, altruism, and compassion. Interpretations about prior relationship experiences underlying the current unsatisfactory exchange help both partners to depersonalize the noxious effects of the other's behavior, to feel less wounded, and consequently to be less reactive in a reciprocally negative manner.

Both individuals are encouraged to be less anxious and less condemning of their own and their partner's emotions, and they are helped to explore and then express their own feelings in a less aggressive or antagonistic fashion. Throughout this process, each individual plays a vital therapeutic role by learning to offer a secure context that facilitates their partner's affective self-disclosures in a softened, more vulnerable manner. The couple therapist models empathic understanding for both partners and encourages new patterns of responding that enhance relationship intimacy. That is, by facilitating the nonoccurrence of expected traumatic experiences in the couple's relationship, both individuals are able to challenge assumptions and expectations comprising underlying maladaptive schemas. Thus, therapeutic change results from the experiential learning in which both partners encounter relationship outcomes different from those expected or feared. In response, partners' interactions become more adaptive and flexible in matching the objective reality of current conflicts and realizing opportunities for satisfying more of each other's needs.

Supporting Evidence

Douglas Snyder and Robert Wills compared their insight-oriented approach emphasizing affective reconstruction with a traditional behavioral couple therapy emphasizing communication skills training and behavior exchange techniques. Thirty couples were randomly assigned to each of these two treatment conditions, and 20 couples were assigned to

a wait-list control group. At termination after approximately 20 sessions, couples in both treatment modalities showed significant gains in relationship satisfaction compared with the control group; specifically, 73 percent of couples receiving the insight-oriented therapy and 62 percent of couples receiving the behavioral therapy experienced significant improvement, in contrast to only 15 percent of the control couples. In addition, couples in both treatment conditions generally maintained their therapeutic gains at 6 months following termination.

However, Snyder and colleagues followed up couples in their treatment study 4 years later and found striking differences between couples treated with insight-oriented versus traditional behavioral therapy. Four years following treatment, 38 percent of the behavioral couples had experienced divorce, in contrast to only 3 percent of couples treated in the insight-oriented condition. Based on these findings, Snyder and colleagues argued that spouses' negative views toward their partner's behavior are modified to a greater degree and in a more persistent manner once individuals come to understand and resolve emotional conflicts they bring to the marriage from their own family and relationship histories.

New Directions

Recent developments regarding IOCT have emphasized assimilation of this approach within multi-theoretical integrative couple treatments. Snyder has emphasized an integrative approach for treating difficult couples in which exploration of developmental sources of relationship distress using IOCT follows more behavioral and cognitive techniques for strengthening the couple dyad and promoting relevant relationship skills. Snyder and colleagues (Donald Baucom and Kristina Gordon) have also developed an integrative approach to treating couples struggling with extramarital affairs, in which interventions derived from IOCT play a central role in examining factors contributing to a partner's affair.

INTEGRATIVE BEHAVIORAL COUPLE THERAPY

Integrative Behavioral Couple Therapy (IBCT), developed by Andrew Christensen and Neil S. Jacobson, is part of what Steve Hayes has called the third wave of behavior therapy. The first wave of behavioral approaches, derived from operant and classical conditioning, sought to create change directly by altering observable antecedent or consequent stimuli such as rewarding desirable behavior. The second wave, coming on the heels of the

cognitive revolution in psychology, emphasized interpretations of behavior in addition to the overt behavior. The third wave emphasizes acceptance, mindful awareness, and direct experience. Rather than trying to control internal negative experiences, third-wave approaches emphasize greater awareness of those experiences, direct exposure to them, and acceptance of them. This entry reviews IBCT and applies its central concepts to interpersonal relationships.

IBCT begins with an evaluation or assessment phase that normally consists of three sessions—a joint session with both partners and an individual session with each partner in which the couple's presenting problems, a brief history of their relationship, and a brief history of each partner's family background are obtained. Following this evaluation period is a feedback session, in which IBCT therapists provide the couple with an overview of their understanding of the couple and recommendations for treatment. The key feature of this feedback is a dyadic conceptualization of the couple's difficulties, emphasizing the key interaction cycles in which the couple gets stuck and the differences between partners and their individual vulnerabilities that fuel this cycle. For example, partners may be locked in a cyclical pattern of demand–withdraw interaction, in which one partner seeks discussion of the relationship while the other avoids those discussions. The “demander” may seek greater closeness in the relationship, fueled in part by a fear of abandonment by the other, whereas the “withdrawer” seeks greater autonomy, fueled in part by a fear of being controlled.

In the research protocol for IBCT, the feedback session is followed by about 20 sessions, typically once a week, of active treatment intervention. These treatment sessions normally involve both members of the couple and are directed at emotionally salient events and issues in the couple's relationships, such as recent examples of their interaction cycle. In the previous example, the therapist and couple might address recent incidents of the demand–withdraw pattern between the couple as they dealt with a situation in which the demander wanted more closeness or the withdrawer was seeking greater independence.

In IBCT, there are three major strategies designed to foster greater awareness and emotional acceptance between partners—*empathic joining*, *unified detachment*, and *tolerance building*—and three

major strategies for fostering deliberate change in partners—*behavioral exchange*, *communication training*, and *problem-solving training*. To promote empathic joining, IBCT therapists try to create a safe environment in which they can elicit partners' unexpressed, or rarely expressed, vulnerable emotional reactions. These reactions may in turn elicit more sympathetic responding by the partner. To promote the joint mindfulness of unified detachment, IBCT therapists have partners step back from their interactions and look at them more objectively, engaging the couple in a joint effort to describe nonjudgmentally the major moves that each partner makes that serve as triggers for the behavior of the other. Partners may have difficulty being empathic with one another or taking a nonjudgmental approach to the other's behavior, but the IBCT therapist maintains a consistent nonjudgmental and empathic approach to both. A variety of strategies are incorporated in tolerance building, such as a discussion of the positive and negative consequences of each partner's characteristics that are upsetting to the other. During behavioral exchange, partners are encouraged to define specific actions each could take that would better the relationship and are encouraged to engage in those behaviors, and the impact is then debriefed. Communication training involves active instruction and practice in speaker skills, such as nonblaming description of problems, and listener skills, such as active listening strategies of paraphrasing and reflection. During problem-solving training, partners are given instruction and practice in defining problems, brainstorming potential solutions, and negotiating agreements. Typically in IBCT, the strategies for promoting emotional acceptance are initiated prior to the strategies for fostering direct change. Often the strategies for promoting emotional acceptance provide the necessary improvement for the couple. As couples near the end of their treatment, sessions may be spaced at greater lengths such as every 2 to 4 weeks to see how couples manage without regular contact with the therapist. A final session involves a review of treatment progress, often centered around the formulation provided in the feedback session.

Three studies have provided evidence for the efficacy of IBCT. A small study showed that a couple group treatment using IBCT was better

than a wait-list control group; another small study showed that, in the short-term, IBCT produced as good or better outcomes than traditional behavioral couple therapy, a well-researched treatment; finally, in the largest clinical trial to date of couple therapy, evidence indicated that IBCT created clinically significant improvement over a 2-year follow-up period in more than two thirds of a sample of seriously and chronically distressed couples. A study of mechanisms of change in treatment showed that IBCT worked by creating change in both the frequency of partners' behaviors, as well as their emotional acceptance of those behaviors (see work by Andrew Christensen, Jennifer G. Wheeler, and Neil S. Jacobson for a review and citations to this research).

INTERACTION ANALYSIS

The term *interaction analysis* is used in a broad sense to refer to a large body of research and theory concerned with understanding how conversation works. Interaction analysis researchers look for systematic devices of discourse used by communicators as they take part in conversation. Interaction analysis is largely concerned

with verbal communication as opposed to non-verbal communication, although nonverbal communication is not excluded in principle, especially nonphonemic properties of speech, such as speaking tempo, silence, vocal pitch, and intonational contours. Research on interaction analysis pays attention to discursive devices related to turn taking, topic selection, purposes of individuals' utterances, interruptions, structure of conversation, relationship between utterances, alignment between communicators, indirectness, metamesages, social actions, frames, background knowledge, context, identities, face, roles, and the relationship between properties of talk and outcomes. This entry addresses key concepts that arise as we develop an understanding of how social interaction works.

Research on conversation tries to understand how individuals coordinate their behavior, and it examines how people create their relationships with one another by talking. Conversation can be seen as a cooperative and collusive activity that is sensitive to reducing the risks to communicators. By risks what is meant are things like being seen in a poor light, as insulting someone when that is not intended or appearing ungrateful or critical. Most of this relational work is done as communicators talk to one another not about their relationship or who they are, but about other things. Conversation is improvisational theater. Utterances, not sentences, are the units of talk; utterances occur at particular points in time and place, and they are intended for particular recipients. Sentences are grammatical units that occur in writing. Utterances may consist of a sound, "uhuh," word, "yes," phrase, "I will," and sometimes a full grammatical sentence, "He did come home." One popular metaphor that has been used to describe conversation is *game*, with moves, rules, goals, and strategies. Another metaphor is *dance*, with one partner taking the lead while being responsive to his or her partner.

As a broadly applied label, interaction analysis covers a number of overlapping approaches, including conversation analysis (with an emphasis on the structure of conversation; e.g., greeting-greeting or summons-response), pragmatics (the principles and mechanisms that allow us to communicate more than is actually said), ethnomethodology (the appropriateness of linguistic behavior), rules theory (the implicit rules communicators follow), and

discourse analysis (a wide-ranging, interdisciplinary study of how people make sense of what they hear and read).

Interaction Analysis: A Specific Method

In its more specific sense, interaction analysis refers to one particular approach to studying conversation, describing discourse by mapping the frequency of occurrence of units of speech in relation to one another, the regular sequences of events (such as a greeting following a greeting or an answer following a request for clarification), and the functions served by those sequences. It is a quantitative approach as opposed to the qualitative approaches of conversation analysis, pragmatics, ethnomethodology, rules theory, and discourse analysis. It is concerned with the temporal sequencing of messages, not the individuals speaking to one another. Interaction analysis as a specific method or approach to studying conversation will take a set of categories to code the talk. For instance, research might look at the occurrence of ambiguous statements followed by requests for clarification. The research is concerned with identifying structures that consist of statements—requests for clarification—statements (called *interacts*). One such study showed that more interacts correlated with greater ambiguity in proposals made at meetings of university faculty senators. Interaction analysis attempts to capture communication process by making use of Markov chain analysis, a mathematical system for assessing the probability of occurrence of sequential events. How often is a greeting followed by a greeting? How often is a highly ambiguous term followed by a message that seeks clarification? Clearly this is an approach to describing discourse that makes use of frequency of occurrence and what sort of utterance is next to what other sort of utterance, usually by using structured, predetermined observational schemes. To understand just how quantitative interaction analysis fits into the larger picture of studying discourse, it is necessary to consider interaction analysis in its broader sense. The next section reviews the questions that have been raised by researchers, some devices that have been posited, and how researchers go about the study of conversation. The entry returns to the approach of quantitative interaction analysis later.

Transmission Model of Communication

A popular conception of communication or social interaction—although an inadequate one—is to picture two people talking to each other and sending or exchanging information. Attached to this imagery is the purpose of the encounter, to transfer or to share information. According to this model of communication, the speaker sends a message to the receiver. The message is sent along auditory and/or visual channels in verbal and/or nonverbal form. Implicit in such definitions are concepts such as two people, message, channel or medium, intent, information, knowledge, meaning, as well as the idea that the message goes in a straight line from one person to another, it starts at one point and ends up at another point. It follows naturally enough that the accuracy and efficiency of the transfer is a measure of the success of the event. This view does not encourage us to stop and think about what goes on when people communicate with one another, how it works, how meaning is assigned to utterances, and what kinds of meaning may be communicated in an utterance.

Many scholars have emphasized the communication of information or propositional meaning in their study of conversation, especially linguists, philosophers of language, and psycholinguists. They have tended to concentrate on the message or the intentional transmission of propositional information, the facts stated, *transactional meaning*. They have tried to understand how this process works. Attention has been paid to syntax, retrieval of stored information, information processing, pattern recognition, and other measurable variables.

More Than Propositional Information

Other scholars have concentrated on social or relational messages communicated in addition to the factual (propositional) messages communicated. They have attended to what sorts of knowledge, beliefs, intentions, assumptions, norms, and relational history must be taken into account in arriving at the meanings communicated. Imagine that, in my telling you that it is raining, I intend for you to know, in addition to the fact that it is raining, that you are forgetting to take your umbrella, that you are forgetful, and that we probably won't be

playing golf later. Moreover, I may communicate in that same utterance that I am pleased by this state of affairs. I am implying that I have a right to communicate those messages to you. I am assuming that we share knowledge. I am assuming that you will know what I am hinting at and that you will be able to apply that knowledge to understand what I am implying. We can refer to this as *interactional meaning*, or meaning that goes beyond the linguistic meaning of my utterance. In other words, you won't find the full meaning(s) of my utterance in the dictionary (i.e., what the utterance would mean to people in everyday life). Hence, scholars of interactional meaning have needed to discuss social variables, pragmatics of everyday life, norms of society, and social actions not required for understanding transactional meaning. By social actions what is meant is what social purposes are served by speaking, such as promising, criticizing, demanding, and threatening. Another way to make the distinction is to refer to language as an abstract, decontextualized system versus language in use. Interactional meaning is language in use.

The study of humans talking to one another and communicating both propositional meaning *and* relational meaning, following the interactional view, has received attention from a variety of theoretical and methodological traditions, including discourse analysis, conversation analysis, and interaction analysis. Researchers have noted that language not only points to a world outside the speaker, it also points to who the speaker is and who the hearer is. A major insight of interaction analysis is that utterances take on meaning against a background of invisible framing, a body of ideas that are used in making sense out of talk but are not visible to communicators. When a young couple was putting away groceries after the young woman had returned from shopping, the young man said, "We need peanut butter." The utterance served not only to state a need, it served to direct the woman to buy peanut butter the next time she goes shopping because it was understood between the two of them that she does the shopping.

The idea that saying something to another person is primarily to inform him or her begins to lose its force when one thinks of those many times when people say something to one another that really does not offer information or does more

than offer information. Telling the person who does the grocery shopping that "we need peanut butter" does more than inform him or her of a state of affairs. Telling someone how cold it is on a brutally cold day does not offer much information; or on a day when you planned to play golf with your roommate and you find there is a snow storm blowing outside your window, saying "what a nice day for golf" does not offer information in any simple, factual sense.

Findings from interaction analysis have added to our understanding of doctor-patient interviews; job interviews; mother-daughter relationships; control tower-pilot exchanges; or the interpersonal effects of gender, social class, ethnicity, culture, and region. For instance, research findings from interaction analysis have shown that just how group members respond to attempts at persuading affects the degree to which a group shifts its attitude in one direction. Supportive reactions to minority arguments in a group were found to result in the group shifting less toward a more extreme final decision. This helps to explain how group dynamics work and suggests how to influence a healthy climate within a group discussion.

Research on conversation has uncovered what men talk about and what women talk about (topics); how messages best provide comforting; how talk both reflects and makes use of "who we are," our identity; how turn taking is managed and what variables affect the perception of being interrupted; how messages are effective in compliance-gaining; and how conflict is managed. One study of job interviews found that successful candidates handled turn taking by giving longer answers to questions than unsuccessful candidates and sometimes taking the role of a storyteller. Research on gender and social interaction shows how varying styles of interacting can produce varied interpretations of social actions. Deborah Tannen has done extensive research on friendship and marital relationships, with special attention to gender styles, regional differences, and relational connections. Studies have found that speakers adjust their accent and rate of speech and their pausing patterns in relation to their conversational partner. This sort of accommodation is found in sales and political speeches. Sometimes the opposite to accommodation occurs when we wish to distance ourselves from our hearer. Some researchers have argued that the

expression of solidarity and power in talk is tied to how we think about these two dimensions—use of frameworks—and thus how we interpret what is said. Many variables influence how people talk to each other and how they understand exchanges. Satisfaction with doctor consultations was found to be more highly correlated with the degree to which doctors asked questions seeking patients' opinions, leaving opportunity for patients to say what they wish to say, as opposed to closed-ended questions, ones seeking information.

Philosophers J. L. Austin and John Searle developed the idea that utterances can communicate social action meaning, which they organized under speech act theory.

According to speech act theory, utterances have, in addition to linguistic meaning or transactional meaning, social action meaning. Under the right circumstances, say at lunch break with a friend, to utter "my sandwich is huge, I couldn't possibly eat it all" could easily serve to indirectly offer some of the speaker's sandwich to his or her friend. The act of offering was referred to as a speech act, and the act was a social action, not just an utterance with linguistic or literal meaning—it did something social. It had meaning as a social action.

From the perspective of conversation analysis, speech acts can be organized into adjacency pairs, where a first pair part is closely related to a second pair part. For instance, a request for information is followed by giving information, an offer is followed by an acceptance or rejection, and a greeting is followed by a greeting. Of course, deciding on just what speech act has been produced is always a question. Was the utterance an insult or a compliment, a claim about the state of the world or a criticism, or a request for information or a reminder that you did not do what you had promised? Just how we make this judgment is by interpreting what an utterance might mean given the relational history between the communicators, frameworks for interpreting, which are based on gender, region, social class and other variables, the immediate conversation, and, most generally, our knowledge of the world.

Complicating speech act theory is the larger context in which utterances are spoken. If the recipient of an utterance is to interpret just what speech act was produced and that interpretation takes into account intentions of the speaker, then

a larger context than the utterance would play a role in the interpretation. Yet speech act theory does not have anything to say about such a larger context. Telling your friend, "Your glass is empty," may serve as an offer, a criticism, or a description. In short, utterances are subject to interpretation.

Quantitative Interaction Analysis

Most approaches to studying conversation tape record and transcribe the talk. Most of the research is nonexperimental and usually does not use interviews. Philosophers and linguists have tended to use hypothetical utterances and constrain their analyses to abstract principles of language. The research done in conversation analysis, discourse analysis, ethnomethodology, and pragmatics has collected naturally occurring, spontaneous speech. Quantitative interaction analysis has more often been used with experimental design or quasi-experimental design. Joseph Capella, well known for his work on quantitative interaction analysis, argued against the limitations of qualitative analyses, pointing to what he called proof by example (i.e., finding examples or excerpts within the data that exemplify various organizing principles).

In contrast to proof by example, Capella argues for proof by data obtained with objective methods of sampling and conclusions reached with statistical testing. Capella argued that proof by example is subject to many alternative explanations in establishing regularity. It is also subject to selection bias on the part of the researcher. In other words, the bias of even the most well-intentioned researcher may influence the results. Accordingly, the quantitative approach buys the researcher some degree of objectivity.

Pulling It All Together

Studies of social interaction under the broader view have suggested that simply looking at sequential order of units omits variables that influence meaning and structure. Hence, interaction analysis researchers have had to find ways to incorporate factors such as who is speaking, the duration of the units, and the latency of pauses. Although mathematical accommodations may be made to integrate additional factors, one is still left wanting to understand what

resides behind such parsimonious equations describing the event (i.e., why did these values occur in this conversation?). The explanatory power of mechanisms that produce regularities in talk push the descriptive Markovian models. For instance, Harvey Sacks, Emanuel Schegloff, and Gail Jefferson suggested the transition-relevance place (TRP) as a *potential* point in the talk where turn change can occur. Such mechanisms are powerful and help to explain structure in conversation. The TRP functions as a highly variable unit that operates on a semantic base. Participants project to the endpoint of a semantic unit, which could be a nonverbal sound, word, clause, or longer. Just which TRP serves to change turns may depend on social and psychological variables, relationship, knowledge, motivation, and more. To map only the actual point of turn change is to miss the potential points of change and the power of the TRP to explain turn change. In other words, potential points of change are not captured by quantitative interaction analysis. Likewise, often what is not said carries more meaning than what is said.

Finally, it should be said that qualitative and quantitative analyses of conversation complement one another. Qualitative analysis of interaction suggests a rich underworld of explanation for what goes on in conversation. Quantitative interaction analysis codifies actual observational categories of speech in relation to one another. If the meaning of a communication event could be captured with just the surface structure, then there would be little need to look further, but that is unlikely.

INTERDEPENDENCE THEORY

Interdependence Theory is one of the few extant theories to provide a comprehensive analysis of interpersonal phenomena. The theory analyzes *interdependence structure*, describing the character of the interpersonal world by identifying crucial properties of interactions and relationships. The theory also analyzes *interdependence processes*, explaining how structure influences emotion, cognition, motivation, and behavior. Harold Kelley and John Thibaut developed interdependence theory over the course of four decades, beginning in the 1950s. Its initial formulation was contemporaneous with early social exchange and game theories, with which it shares some postulates. This entry reviews key concepts and principles of the theory.

Interdependence Structure

Interdependence Theory presents a formal analysis of the abstract properties of social situations. Rather than examining concrete social elements such as “professor threatens student” or “woman argues with man,” the theory identifies abstract

elements such as “dependence is nonmutual” or “partners’ interests conflict.” Hence, the theory allows scientists to understand situations that might differ in their superficial character, but that share crucial abstract properties. These abstract features of a situation constitute its “interpersonal reality”—a reality that causes people to think, feel, and behave in predictable ways.

The basic unit of interpersonal experience is an *interaction*: Each of two or more people can enact any of two or more behaviors. As a result of their choices, each person experiences good versus poor *outcomes*—consequences that are more versus less satisfying or pleasurable. The outcome of an interaction is satisfying to the extent that it gratifies (vs. frustrates) the individual’s important needs, such as companionship, belongingness, and exploration.

Interdependence Theory analyzes the ways in which people affect their own and each other’s outcomes, describing social situations in terms of six structural dimensions (see below). Most situations are defined by two or more dimensions, such that the key dimensions of interdependence are the building blocks of structure. Specific structural patterns are meaningful in that they activate specific sorts of goals and motives, influence cognition and emotion, and thereby shape behavior. As such, situations also determine what people can learn about and communicate to one another. The concept of *affordance* describes the implications of a specific situation for specific types of cognition, emotion, and motivation, identifying that which a situation makes possible or may activate in interaction partners.

Dimensions of Interdependence Structure

Level of dependence describes the degree to which an individual’s outcomes are influenced by the partner’s actions. John is more dependent when Mary—through her actions—can cause John to experience good versus poor outcomes. He is independent when her actions do not affect his well-being. Dependence is the converse of partner power—when John is dependent on Mary, Mary holds power over John. Although dependence causes people to persist in relationships, it also makes people vulnerable and exposes them to possible exploitation. Therefore, dependence affords people’s

thoughts and motives about trusting and depending on others versus remaining independent of others.

Mutuality of dependence describes the degree to which partners are equally dependent. Mutual dependence exists when Mary is as dependent on John as he is on her. Unilateral dependence exists when Mary is more dependent on John than John is on her, such that John holds greater power than Mary. Mutual dependence constitutes balance of power and tends to yield more stable and secure interaction. Situations with unilateral dependence entail risk, in that unilaterally powerful partners may behave as they wish without concern for others’ well-being—unilaterally dependent partners are vulnerable to possible exploitation or abandonment. Thus, situations with unilateral dependence afford thoughts and motives about vulnerability (for the more dependent partner) and responsibility (for the less dependent partner) and give the less dependent partner the opportunity to behave in a generous or heroic manner.

Basis of dependence describes the manner in which partners influence one another’s outcomes. Dependence may rest on partner control, where John’s outcomes are governed by Mary’s unilateral actions, versus joint control, where John’s outcomes are governed by their joint actions. Partner control is absolute and externally controlled, in that John’s outcomes are entirely governed by Mary’s behavior; such situations tend to promote exchange-based interaction (trading favors) and are governed by morality norms. Joint control is contingent, in that John’s outcomes rest on coordination with Mary (if he can predict her actions, he can modify his behavior and achieve good outcomes); such situations tend to promote simple coordination and are governed by norms of “good sense.” Thus, the basis of dependence affords the expression of dominance and assertiveness (vs. submissiveness or passivity; e.g., suggesting a pattern of fair exchange, taking the lead in coordinating action).

Covariation of interests describes the degree to which partners’ outcomes correspond—whether events that benefit John are similarly beneficial for Mary. Covariation ranges from correspondent situations (what is good for John is also good for Mary) through mixed-motive situations to

situations with conflicting interests (“zero sum”; what is good for John is bad for Mary). Interaction is simple when interests correspond—John can simply pursue his interests, knowing that doing so will also yield good outcomes for Mary. Interaction is simple when interests conflict—one person must lose if the other is to gain, so each person tries to “come out on top.” Mixed-motive situations are more complex, pitting impulses to benefit the other against temptation to exploit, thereby affording the expression of cooperation and trust (vs. competition or mistrust).

Temporal structure describes the fact that interactions are dynamic and evolve over time. Interaction must be understood not only in terms of the immediate outcomes produced by partners’ choices, but also in terms of the future behaviors and outcomes that are made available versus eliminated as a result of interaction. For example, John and Mary may make an extended series of investments to develop a committed relationship. For example, by behaving in a particular manner today, they may proceed down a path where only poor outcomes are available for one or both partners. Temporally extended situations afford the expression of dependability versus unreliability and loyalty versus disloyalty.

Availability of information is the sixth dimension. John and Mary may possess complete versus incomplete information about their own or the other’s outcomes for various combinations of behavior (“How does Mary feel about marriage?”), the partner’s motives (“Will Mary use her power benevolently?”), or future interaction possibilities (“If we do this now, where will it take us?”). Information is especially critical in novel or risky situations and in interactions with unfamiliar partners. Inadequate information gives rise to ambiguity and misunderstanding, thereby challenging interaction. Thus, incomplete information affords the expression of optimism versus pessimism, as well as tolerance for ambiguity versus the need for certainty.

Interdependence Processes

Human cognition is inherently interpersonal—humans are well prepared to recognize key properties of interdependence situations. Indeed,

interactions are shaped not only by interdependence structure, but also by partners’ needs, thoughts, and motives in relation to one another in the context of the situation in which the interaction takes place. Thus, it is important to understand how situation structure affords specific sorts of affect, cognition, and motivation.

Transformation. To describe the interface between interdependence structure and process, interdependence theory distinguishes between: (a) the *given situation*, or behavioral preferences based on the reality of self-interest as represented in situation structure; and (b) the *effective situation*, or preferences based on broader psychological considerations. *Transformation* is the motivational process whereby people depart from situation-based self-interest, instead reacting on the basis of broader considerations, such as long-term goals, the well-being of a partner, or stable traits or motives. The transformation process may rest on systematic thought or automatic habits. It is through this process that an individual’s unique “self” is revealed. For example, if Mary decides to take care of John when he is ill rather than going out with her friends, she reveals her concern for him. Because Mary departs from that which is dictated by the given situation (her desire to go out with her friends), her unique traits and motives become visible (i.e., her compassion, feeling of responsibility for John’s well-being).

Attribution process and self-presentation. People engage in *attribution processes* to understand the implications of their partners’ behavior in specific situations. During the attribution process, people seek to explain prior behavior and predict future behavior via an analysis of the meaning of behavior in light of specific patterns of interdependence structure (“Is John concerned about my needs?”). In like manner, through *self-presentation* people attempt to communicate the implications of their own actions via deviations from the dictates of self-interest (“See, you can trust me”). Of course, people cannot communicate or discern all motives in all situations, in that specific motives are relevant to specific types of situation. For example, in situations with perfectly corresponding interests, John cannot display trustworthiness—if he behaves in ways that benefit Mary, he is likewise benefited, such that it is impossible

to determine whether he is driven by self-interest or prosocial motives.

Adaptation. Where do the motives that guide the transformation process come from? In a novel situation, John may treat the situation as a unique problem, carefully examining his options; alternatively, he may react impulsively. In either event, he acquires experience: If his reaction yields poor outcomes, he may behave differently in future, parallel situations; if his reaction yields good outcomes, he is more likely to react similarly in future, parallel situations. *Adaptation* describes the processes whereby repeated experience in situations with similar structure give rise to stable transformation tendencies that on average yield good outcomes. Stable adaptations may reside within persons, relationships, or groups (see below).

Interpersonal dispositions are actor-specific inclinations to respond to specific situations in a specific manner across numerous partners. Over the course of development, people undergo different experiences with kin and peers. As a result, people acquire dispositions to perceive situations in specific ways, anticipate specific motives from others, and transform situations in predictable ways. In short, the “self” is the sum of one’s adaptations to previous interdependence problems. For example, if John benefited from good caregiving as a child, he is likely to feel more comfortable with dependence, which may cause him to behave in a more trusting manner in situations involving high dependence and conflicting interests.

Relationship-specific motives are inclinations to respond to situations in a specific manner with specific partners. For example, Mary’s trust reflects her confidence in John’s benevolence. Mary develops trust when John enacts a prosocial behavior, departing from his self-interest to promote her welfare. His actions communicate responsiveness to her needs, thereby enhancing Mary’s trust in his motives, causing her to feel less fearful in situations involving conflicting interests, encouraging prosocial transformation, and thereby enhancing the probability of reciprocal benevolence. This form of trust is relationship-specific and exists above and beyond generalized tendencies people possess based on their longstanding dispositions.

Social norms are rule-based, socially transmitted inclinations to respond to particular situations in a specific manner. For example, societies develop rules regarding the expression of anger; such rules help groups avoid the chaos that would ensue if people were to freely express hostility. Likewise, dyads may also develop relationship-specific norms that promote harmonious day-to-day interaction (e.g., agreements about the fair division of household chores).

Conclusion

Interdependence Theory provides unique and necessary tools for analyzing *interpersonal* phenomena. Whereas most psychological theories focus on the individual, suggesting that people behave as they do because of their unique traits or cognitions, in interdependence theory, the relationships *between* people are as important as the people. Thus, the theory represents an elegant, functional model of the nature and implications of interdependence. It is a truly *social* psychological theory.

INTERGENERATIONAL FAMILY RELATIONSHIPS

Ties between the generations have been of great interest throughout recorded history, as demonstrated by

the central role of these relationships in popular works of fiction as varied as Shakespeare's plays in the 16th century and Bernhard Schlink's novel *Homecoming* and the television series *Everybody Loves Raymond* in the 21st century. Not surprisingly, both clinicians and scholars have devoted substantial effort to describing and explaining relations among family members in different generations. This high level of professional and popular attention is consistent with the importance that individuals place on their family relationships. Indeed, given high rates of divorce and geographic mobility in contemporary society, relationships between parents and children are likely to be the most stable and long-term ties that people experience. Further, research has shown that both parents' and children's well-being is affected by the quality of their relationship and by the problems they each experience. Thus, there is ample evidence to demonstrate the centrality of this intergenerational tie.

This entry begins by describing historical and demographic trends in intergenerational relationships, followed by discussion of the factors that characterize parent-child relationships that are the most satisfying and stable. The entry then turns to two issues of concern to aging families: caregiving to frail parents and elder maltreatment. Finally, the entry describes trends in grandparent-grandchild relations, a tie that has become increasingly complex in recent decades due to increased life expectancy and increasing rates of difficulties in the lives of many adult children.

Historical and Demographic Trends

Several trends over the last century have affected intergenerational relationships. The trend that has had the greatest impact is the dramatically lengthened life span; for a child born in 1900, life expectancy was 48 years; by 2005, it had increased to nearly 78 years. Perhaps even more important, for individuals who are now about 50 years of age, the life expectancy for women is 33 additional years and for men it is 29 years. Thus, family members now spend more time occupying intergenerational family roles as adult children, parents, and grandparents than did any earlier cohorts.

The second major demographic change is a decline in parent-adult child coresidence. Coresidence with adult children when parents entered their later years was common in earlier historical

periods; however, there was a dramatic decline in this pattern across the 20th century in the United States. Nevertheless, many parents and adult children still coreside, although more recently coresidence typically involves the adult child living in the parents' home rather than the reverse. According to the U.S. Census Bureau, in 2006, 22 percent of householders 65 and older had an adult child living with them, whereas only 3 percent of householders ages 25 to 54 had an older family member coresiding.

The third important change involves women's increased participation in the labor force, reducing the time and energy devoted to "kinkeeping." In fact, married women's labor force participation has increased from 30 to 60 percent since 1970 alone. Although one might expect that this demographic change would lead to women doing markedly less caregiving, in most cases, women instead expand their responsibilities to meet their older parents' need for assistance.

Finally, the paths that current middle-age Americans (referred to as the "baby boomers") have followed differ from earlier cohorts in ways that affect kin relations. Compared with earlier cohorts, baby boomers have been more likely to remain unmarried, have lower birth rates, and become divorced, each of which tends to weaken intergenerational ties, particularly for men.

Although these sociodemographic transitions have changed the face of family life in the past several decades, research has shown that none has reduced the importance of the parent-child relationship in adulthood. Both high levels of contact and mutually supportive exchanges are reported by parents and their adult children despite the presence of conflict and ambivalence common to intimate interpersonal relations. Further, at the end of parents' lives, adult children often provide care and support, particularly when a parent is widowed.

Closeness and Contact Between Parents and Adult Children

In the 1950s and 1960s, scholars expressed concern that intergenerational contact and support were increasingly threatened by industrialized societies. However, research has demonstrated these concerns were unfounded. Most parents and

adult children have relatively frequent and regular contact with parents despite that adult children are more likely to live farther away from their families of origin than were previous cohorts. Further, studies of the quality of relations between the generations find consistent evidence that the emotional ties between parents and adult children remain strong, particularly between women in the family. Recent investigations have revealed that conflict and ambivalence are more common characteristics of intergenerational relations than previously thought; nevertheless, the most prominent pattern of parent–adult child relations continues to be positive and supportive.

Exchange of Support, Parental Dependency, and Family Caregiving

Most families are characterized by mutual exchange between the generations, typically following a pattern reflecting the life course stages of parents and adult children. When offspring are young adults, support tends to flow from parent to child in the form of assistance in establishing independent lives. As children leave young adulthood, support still generally flows from parent to child, but usually diminishes somewhat. It is typically only in the late stages of the parents' life that the direction of support flows more heavily from child to parent.

Most assistance provided to parents is routine and produces little strain; however, as parents age and experience declines in health and income, adult children are increasingly likely to assume the role of family caregiver. This represents a major life-course transition for adult children that typically has far-reaching consequences for the caregiver's physical, mental, and social well-being. This is particularly the case if the parent has developed Alzheimer's disease or some other form of irreversible dementia.

Studies have focused primarily on the difficulties that adult children experience when they begin caring for older parents. This line of research has shown that parents' increased dependence on their adult children often reduces positive feelings between the generations while increasing children's difficulty managing the competing roles of spouse, parent, and worker. Not surprisingly, caregiving is often associated with increases in adult children's physical and emotional stress.

However, the effects of caregiving are not uniformly bleak. First, studies have found that many caregivers identify positive consequences of caregiving, such as feelings of gratification derived from helping someone they love and fulfilling expectations of filial responsibility. Second, several circumstances affect the consequences of caregiving on adult children. For example, caregiving is associated with fewer negative and more positive outcomes when the parent and child have a history of closeness and support and when there is little conflict among siblings regarding parent care. Further, among married adult daughters, those whose husbands are supportive of the daughters' caregiving efforts experience more positive outcomes. Recent studies have shown that parents have specific expectations and preferences regarding which of their children take primary responsibility for caregiving. Future research may reveal that caregiving outcomes are better for both parents and children when those preferences and expectations are met. Understanding the factors that improve the quality of the caregiving experience may also be an important key to reducing the risk of elder maltreatment because individuals most likely to need assistance—those with physical and psychological impairments—are at a higher risk of becoming victims of such maltreatment than are more healthy persons.

Determinants of the Quality of Parent–Child Relationships

Understanding the quality of parent–adult child relations has been of great interest to scholars and clinicians. The most consistent finding in studies of intergenerational relations is the primacy of the bond between mothers and daughters, which is stronger than that of any other gender combination in the family. Children's transitions into adult social statuses also typically improve relations between the generations. For example, the parent–child tie becomes more harmonious as adolescents move into adulthood, and it continues to strengthen as both children and parents move across the life course. Further, there is generally increased closeness when children begin to share a large number of adult statuses with their parents, such as employment, marriage, and parenthood. However, the trend toward greater closeness when children attain

adult status is not always straightforward because some adult transitions (such as becoming a parent) also increase competition for scarce time and energy, leaving fewer resources for intergenerational relationships. Nevertheless, children's transitions into adult status increase the similarity of values and interests between parents and children, which enhance closeness and reduce conflict.

Recent studies have shown that parents often differentiate among their adult children in terms of emotional closeness, preferences for support, and provision of support to the younger generation. The factors just discussed are the best predictors of which children are most likely to be favored—daughters and children who are more similar to the parents in terms of values and social structural positions. In addition, parents favor children who live nearby.

Major problems in adult children's lives have been shown to have detrimental effects on parent-child relationships. For example, parents are likely to experience poorer relationships with children who have mental, physical, substance abuse, or stress-related problems. Such problems have stronger effects on parent-child conflict and ambivalence than parents' feelings of emotional closeness toward their children. Not surprisingly, problems for which children are perceived as not responsible, such as illness, have fewer negative effects than those for which they are perceived as responsible, such as substance abuse or trouble with the law. Regardless of whether the problem is voluntary, children's difficulties have been found to affect their parents' physical and psychological well-being.

Adult children's problems also increase the risk of elder maltreatment. In fact, children's problems are a better predictor of elder maltreatment than parents' dependency. Abusive adult children are likely to be financially dependent, live with their parent(s), have problems related to alcohol and drugs, and have some indication of socioemotional maladjustment.

Diversity and Older Parent-Adult Child Relations

Studies have revealed both similarities and differences in intergenerational relationships among racial and ethnic groups. Both parents and children of all racial and ethnic groups appear to place

substantial importance on both the emotional and instrumental aspects of intergenerational relations, reporting high levels of closeness, as well as regular contact and a history of exchange. However, research has revealed notable racial and ethnic variations in these relationships. African Americans and Hispanics appear to have stronger ideals regarding filial obligations than do their White Anglo counterparts, and they are more likely to exchange support. Further, older African Americans and Hispanics are more likely to live with their adult children. Both African-American parents and adult children report higher levels of closeness and lower levels of conflict than do Whites; however, such differences are not found between Whites and Hispanics. Comparisons reveal greater filial responsibility, exchange of support, and intergenerational coresidence among Asian Americans than Anglos, but substantial diversity among Asian subgroups regarding intergenerational support. Rapidly expanding diversity in the United States makes it increasingly important to understand patterns and consequences of racial and ethnic variations in older parent-adult child relations.

Grandparents and Grandchildren

In recent years, popular and scholarly interest in relationships between grandchildren and grandparents has grown. This can, in part, be attributed to the historical and demographic changes outlined earlier, each of which has influenced the role of grandparenting as well as parenting. First, due to increasing life expectancy, most parents of adult children will occupy the role of grandparent for nearly one third of their lives. Second, the effects of high rates of divorce extend to ties between grandparents and grandchildren. Adult children's divorces often reduce contact and closeness between grandparents and grandchildren—particularly on the father's side of the family. Third, although intergenerational coresidence has declined overall across the past century, such residential arrangements remain common in Black and Hispanic families, thus providing higher levels of grandchild-grandparent contact in these groups than that found in White families.

Grandparents often play a major role in raising their grandchildren. In coresidential families in which parents are present, grandparents are less

burdened by parenting stress, and can serve primarily as a source of support; however, when grandparents serve as sole guardians of grandchildren, they are more likely to experience decreased well-being—particularly greater depression and lower life satisfaction.

Predictors of the quality of grandparent–grandchild relations are well documented. Closeness and contact are greater when the generations live near each other and when grandparents are better educated, healthy, have fewer grandchildren, and are married. Families living in rural areas also have stronger intergenerational links. Other relations in the family also affect the quality of the grandparent–grandchild tie. For example, grandparents are likely to be more supportive and attentive to grandchildren if they had positive childhood experiences with their own grandparents. Also, grandparent–grandchild ties depend heavily on relationships with the parent generation. If there is high affectional solidarity and support between the grandparents and parents, the relationships between grandparents and grandchildren will also tend to be strong.

Professionals have labeled this phenomenon “the cycle of violence” or “the intergenerational transmission of violence,” and it is the most heavily researched phenomenon within family maltreatment. Is there merit to these assumptions? If so, how strong is the effect? This entry reviews what has been learned, focusing on conceptualization of the phenomenon, extent of transmission, and possible mechanisms by which transmission may occur.

Conceptualization

One might think that intergenerational transmission of abuse would be a relatively straightforward concept; however, this is not the case. Children can be direct victims of maltreatment, they can be exposed to interparental violence, or both. As adults, they can maltreat their own children, they can perpetrate or be victimized by partner violence, or both. Maltreatment can be further subdivided into physical, emotional, sexual, and/or neglect subtypes.

In research, the definitions of maltreatment vary widely. Many studies follow children who were substantiated by local Child Protective Services (CPS) as being maltreated. However, state statutes vary widely, as do local CPS’ de facto standards for what is substantiated as maltreatment. In studies that rely on self- or parent reports of maltreatment, researchers frequently rely on reports of behaviors (e.g., being struck by a parent) without requiring impact on the victim (e.g., bruises) or extreme danger, as CPS investigations would. Furthermore, victims often experience more than one subtype of abuse (e.g., both physical and emotional), and child and partner maltreatment often co-occur in the same homes. With such variety in what can be and has been examined, interpretation and comparison of abuse research findings is often difficult. This entry is as specific as space will allow; interested readers will find more detailed information in the supplementary readings.

INTERGENERATIONAL TRANSMISSION OF ABUSE

Most people believe that most or all abusive adults must have been exposed to abuse as children.

Extent of Transmission

What effect does the presence of violence or abuse in a childhood home (i.e., “family of origin” [FOO]) have on the probability that a particular type of abuse will be present in the adult homes of

former victims? The scientific research literature is summarized later, broken down by type of abuse (i.e., physical, emotional, sexual, or neglect). Overall, the effects found have been statistically significant, but only small to medium in size. There is evidence that risk of transmission may increase (a) with frequency or severity of abuse, and/or (b) when exposure to multiple types of abuse has occurred.

Physical Abuse

The vast majority of research on the intergenerational transmission of abuse has been conducted regarding physical abuse. There are two primary lines of inquiry: transmission of child physical abuse and transmission of intimate partner violence (IPV).

Child physical abuse. Most studies of the transmission of physical violence toward children have focused on mothers', rather than fathers', FOO histories. Parents who were physically punished as children—particularly during adolescence—are at higher risk of perpetrating both minor and severe violence toward their own children; for mothers, the effect is stronger if it was their own mothers who abused them. Witnessing IPV during childhood also increases risk of child physical abuse perpetration in adulthood.

IPV. Research has shown that children who are physically, sexually, or emotionally abused—or witness either parent being physically or emotionally aggressive toward someone else—are at increased risk of perpetrating and/or experiencing IPV as adults. Although the risk of both perpetration and victimization is amplified for all children who grow up in violent homes, boys appear to be at more greatly increased risk than girls for becoming IPV perpetrators, whereas girls are at more greatly increased risk than boys of becoming IPV victims.

Emotional Abuse

Little research has been done on the transmission of emotional abuse; the few studies that do exist are difficult to interpret and compare because (a) definitions of emotional abuse vary dramatically, and (b) emotional abuse is usually

not considered in isolation, but combined with other types of abuse. It does appear that experiencing or witnessing physical or emotional violence on the part of either parent places a child at increased risk of perpetrating and/or experiencing emotional violence in later romantic relationships, although the effects found so far have been small.

Sexual Abuse

Gauging the extent of intergenerational transmission of sexual abuse is difficult because most child sexual abuse studies do not distinguish between extra- and intrafamilial perpetrators. The vast majority of rapes and sexual abuse incidents are perpetrated by males; however, there is some evidence that a history of childhood sexual victimization may increase the risk of child sexual abuse perpetration for both men and women. In fact, parents who were sexually abused as children are at greatly increased risk of having a sexually abused child even if they themselves are not the perpetrators.

Neglect

Child neglect is by far the most common form of child maltreatment in the United States, but has received relatively little research attention, particularly in terms of intergenerational transmission. This is likely due to difficulty and wide variability in operationalizing neglect. There is some evidence that parents neglected as children may be at increased risk of neglecting their own children, but the transmission effect, if it indeed exists, appears to be weak.

Possible Mechanisms of Transmission

Studies have begun to illuminate how the cycle of family violence may operate. Some of the mechanisms of transmission that have received the most research support include modeling, poor parenting, and transmission of risk.

Modeling

Modeling, or observational learning, is considered to be a primary cause of the intergenerational transmission of abuse. Behavioral modeling generally refers to the tendency for someone who notices the success of others' behavior to imitate it, hoping for a

similar outcome. If the imitated behavior does indeed obtain the desired result, the probability that the behavior will be repeated increases (i.e., operant conditioning). Thus, children see that violence against themselves or loved ones works in getting something that the perpetrator wants. When they later want something themselves, they imitate what they have observed and use violence to obtain it; thus, victimized children learn to victimize others.

Poor Parenting

Not surprisingly, parents who abuse each other and/or their children also tend to be poor parents who have less-than-diligent monitoring habits and utilize ineffective discipline strategies that are overly harsh and coercive. Moreover, children of ineffective parents are at increased risk for a host of negative outcomes, including failure in school, work, and interpersonal relationships; anxiety, depression, and personality problems; association with deviant peers; substance abuse and conduct problems; and problems with anger control and interpersonal violence. The increased risk occurs even if parents cannot be termed abusive; thus, it appears likely that poor parenting is the driving factor, rather than abuse as such.

Transmission of Other Factors That Increase Risk

It should also be noted that troubled children tend to form romantic relationships with each other (i.e., assortative mating); any children born to such a couple are likely to receive a “double dose” of risk. Risk factors for abuse that may be passed on from one or both parents may be biological, cognitive, emotional, or environmental. For example:

- Genetic factors that predispose one generation toward violence may be passed on to the next.
- Abusive parents tend to attribute their children’s undesirable behavior to negative personality traits and hostile intent, and children whose parents make such attributions about them tend to make such attributions about others.
- Children of parents who habitually and rapidly escalate when they get angry tend to develop similarly poor emotion-regulation skills.
- Children who grow up in poverty-stricken, high-crime neighborhoods tend to remain in them as adults.

In part because risk factors for abuse can be passed on from generation to generation, abuse can even be transmitted in a seemingly indirect way. For example, children (particularly girls) whose mothers have a history of childhood sexual victimization are three or more times more likely than other children to be sexually victimized themselves, although it is virtually never the former victim (i.e., the mother) who perpetrates the abuse. This is most likely because former sexual abuse victims have higher rates of several maternal characteristics that are known to place children at increased risk of being sexually abused—for example, mental illness, substance abuse, and becoming romantically involved with violent men.

Conclusions

Despite definitional and methodological inconsistencies within the literature, there is support for the hypothesis that intergenerational transmission of family maltreatment does occur. However, contrary to popular belief, the effects of childhood exposure are nowhere near universal. For children of former child abuse victims, the best estimates available predict about a one in three probability of exposure to abuse. Sobering as this forecast is, it should be noted that there is also hope, in that the majority of children of former victims will seemingly grow up without being abused, neglected, or in a relationship characterized by intimate partner violence. Unfortunately, relatively little research has been conducted into possible reasons, causes, or mechanisms for nontransmission of abuse. Quite often, it appears, the apple does indeed travel far from the tree, but the field does not yet know why most seeds of family violence, planted during childhood, never sprout.

INTERGENERATIONAL TRANSMISSION OF DIVORCE

The intergenerational transmission of divorce (alternately, the divorce cycle) refers to the propensity for people to end their own marriages as a result of growing up in a divorced family. Social scientists first suggested that divorce might run in families in the 1930s. Since then, more than 25 studies have confirmed that the adult children of divorce dissolve their own marriages with disproportionate frequency. This entry provides a brief overview of the intergenerational transmission of divorce.

For the social scientist, divorce provides a fabulous independent variable: It has strong and generally negative effects on almost every aspect of people's economic, social, and psychological lives. Compared with their married counterparts, divorcees generally are poorer, more depressed, and less physically healthy. Marital disruption has similarly wide-ranging negative effects on offspring. Compared with youth in intact families, the children of divorce do worse in school, are more likely to be substance abusers, are less happy, and as adults have worse jobs and less money. Few social scientists question these findings. There is even evidence that, all else being equal, people from divorced families do not live as long as people who grew up with two biological parents.

Parental divorce has implications for almost every aspect of children's behavior in romantic relationships. Teenagers from divorced families date more, have sex earlier, and, if women, are disproportionately likely to get pregnant out of wedlock. Teenage girls from divorced families even have their periods earlier than do their counterparts from intact families. People from divorced families also think about intimate relationships differently. Compared with their peers from intact families, the adult children of divorce view marriage less favorably and divorce less unfavorably.

Parental Divorce and Offspring Marital Behavior

Given the differences between people from divorced and intact families, it should come as little surprise that the children of divorce have distinctive marital behavior. This behavior is important for understanding why divorce rates are higher for people from nonintact families.

For many years, social scientists were divided as to whether parental divorce made marriage more or less likely among adult offspring. The answer is both. The children of divorce have disproportionately high marriage rates through age 20. However, if they remain single past that point, they are about one third less likely to ever get married, compared with their peers from intact families.

How can this pattern be explained? The children of divorce sometimes wed in order to escape unpleasant home lives; this is particularly true for

youth living in stepfamilies. As previously noted, parental divorce increases the incidence of teen sexual activity and, for women, nonmarital births. Early sex and pregnancy may in turn lead to early marriage. Past age 20, there are several reasons that the children of divorce have lower marriage rates than do their counterparts from intact families. First, marriage may simply seem unappealing to some people who grew up in divorced families. Perhaps fearful of repeating their parents' experience, living with a partner out of wedlock may seem preferable; indeed, the children of divorce have high rates of nonmarital cohabitation and are more inclined to view cohabitation favorably. Half of the disparity in marriage rates between people from divorced and intact families can in fact be explained by the former's propensity to cohabit. Second, past age 20, the children of divorce may avoid marriage for the same reasons they have high divorce rates. As is shown, people who grew up in divorced families often have trouble in their own marriages because they evince problematic interpersonal behaviors. Assuming these behaviors are present prior to marriage, they may interfere with the formation of lasting relationships.

Parental divorce also influences how people go about picking spouses. In particular, people from divorced families often marry other people from divorced families. This proclivity, which has been called *family structure homogamy*, goes a long way toward explaining why the children of divorce have high divorce rates. How can family structure homogamy be explained? Parental divorce provides a broad common ground of painful and poignant experiences. As children grow up, these experiences may become ingrained, making it harder to relate to people who feel differently about intimate relationships. A prospective mate from a divorced family has had a wealth of similar experiences. He or she may be able to empathize with the anguish, anxiety, and anger of parental divorce, whereas someone from an intact family might not be able to do so.

Explaining Divorce Transmission

Although the divorce cycle has been studied for many years, it is only in the last two decades that multivariate analysis has enabled scholars to

pinpoint the reasons that parental divorce increases the likelihood of dissolving one's own marriage. The first task was to rule out the confounding influences of race, education, marriage timing, and other demographic differences between people from married and divorced families. For instance, African Americans have traditionally had higher divorce rates than Whites. It is also known that parental divorce reduces offspring educational attainment and increases the odds of a teenage marriage. Race, low educational attainment, and youthful marriage are all noteworthy predictors of divorce. Perhaps these differences, not the effects of parental divorce per se, are responsible for the intergenerational transmission of marital instability. These factors all make a difference, but collectively they can account for at most one third of the divorce cycle.

With one caveat, the rest is directly attributable to the experience of parental divorce. Thanks in large part to the research of Paul Amato, two psychological mechanisms for divorce transmission have been identified. The first is problematic interpersonal skills. Adult children of divorce often engage in behaviors that are not conducive to maintaining a lasting interpersonal relationship. A long list of these behaviors has been proposed; examples include anger, jealousy, submissiveness, poor conflict resolution skills, and distrustfulness. Statistically controlling for these and other behaviors can account for the relationship between growing up in a nonintact family and the likelihood of dissolving one's own marriage. Note that this finding precludes many traditional explanations for the intergenerational transmission of divorce, including role modeling—parental divorce instills offspring with prodivorce attitudes that ultimately engender divorce transmission—and the notion that the divorce cycle is entirely attributable to the social and demographic correlates of marital instability.

The second explanation for the intergenerational transmission of divorce concerns marital commitment. Social science has repeatedly shown that parental conflict is bad for offspring; the more conflict, the worse children do across a variety of social and psychological outcomes. However, parental conflict does appear to have one benefit for offspring. Divorce transmission is weaker for offspring who endured high-conflict parental divorces. Conversely, adults from divorced families

have the highest divorce rates when their parents' marriages ended after virtually no acrimony. Parental conflict teaches children to remain in their own marriages no matter what happens. When parents divorce after virtually no conflict, children may not learn the persistence that a successful marriage ultimately requires.

The exception to these explanations for the divorce cycle is the role played by genetics. In research based on twins, researchers have shown that a portion of the intergenerational transmission of divorce can be attributed to genetics rather than behavior. The reasoning is this: Some people are innately difficult, and their problematic interpersonal behaviors are conferred genetically as well as socially. Recipients of this "difficult gene" often have trouble in their own marriages; thus, their troubles may have a purely biological component. The scholars who conducted this research concluded that genetics only play a partial role in explaining divorce. Genetics cannot account for why the divorce rate skyrocketed between 1965 and 1985, or why the divorce cycle has weakened over time, as discussed next.

How Strong Is the Divorce Cycle?

The strength of the divorce cycle varies according to the historical period the divorce data were collected in, how parental divorce is measured, and whether the analysis controls for social and demographic differences between respondents. Irrespective of these factors, parental divorce increases the likelihood that adult offspring will dissolve their own marriages by at least 40 percent. Under some conditions, the children of divorce are three times as likely to get divorced as are their peers from intact families.

The most important predictor of divorce transmission is the extent of a couple's exposure to parental divorce. Each spouse's experience with parental divorce contributes separately and additively to the probability that their own marriage will dissolve. Thus, marriages between people from intact families have the lowest divorce rates, unions containing one child of divorce are in the middle, and marriages between people from divorced families have the highest chances of dissolution. Furthermore, the odds of divorce transmission are

the same whether it is the husband or the wife who hails from a divorced family. People from divorced families exhibit behaviors not conducive to maintaining happy marriages; family structure homogeneity compounds these problems by uniting two people who are ill disposed to marital success.

Multiple family disruptions while growing up incrementally increase the likelihood of dissolving one's own marriage. People whose divorced parents remarry are more likely to dissolve their own marriages than are their peers experiencing parental divorce but not remarriage; multiple parental divorces produce even higher divorce rates in offspring. Also, people experiencing multiple family structure transitions while growing up are more likely to dissolve multiple marriages as adults; the divorce cycle holds for second and third marriages as well as initial unions. People often repeat the patterns of marital behavior they learned growing up.

Trends in Divorce Transmission

Divorce in America has changed substantially over the past 50 years. Concomitant with increases in the divorce rate has been a sea change in how people view ending a marriage. In 1952, voters were more concerned about Democratic presidential nominee Adlai Stevenson's divorce than they were about the threat of domestic communism. Less than 30 years later, Ronald Reagan's divorce was the nonevent of his successful presidential campaign in 1980. This comparison of two presidential hopefuls shows how divorce went from stigma to commonplace in a relatively short period of time.

The result has been a dramatic change in the divorce cycle. Survey respondents who grew up in divorced (but not remarried) families that were polled in 1973 were 126 percent more likely to have dissolved their own marriages than were otherwise comparable individuals from intact families. By 1994, the disparity had declined to 45 percent. Thus, the intergenerational transmission of divorce weakened over the same years that the divorce rate in America increased. At least in this one respect, divorce no longer appears to hurt offspring as much as it once did. There has been no change in the divorce cycle for offspring experiencing both parental divorce and remarriage.

The declining marriage rate for people from divorced families has played a small role in the weakening divorce cycle, but a larger part is directly attributable to the changing message (Note missing letter) children receive when their parents get divorced. Recall that the divorce cycle can be attributed to the reduced commitment to marriage that results from growing up in a divorced family. The message that children received about commitment was doubtless much stronger in the days when almost nobody got divorced because it stood out more starkly against the experiences of one's peers (few of whom likely came from divorced families). Under these conditions, children learned that it might be preferable not to stay in a marriage that had turned sour. These lessons were doubtless reinforced by the stigma and shame of life in a single-parent family. In contrast, no matter how painful it is at the time, a modern divorce does not stand out against the experiences of one's peers and therefore does not send nearly as strong a message to children. This is the most likely reason that the divorce cycle weakened during the latter third of the 20th century. Declining stigma may have also affected rates of divorce transmission.

attract or is it the case that birds of a feather flock together? In recent decades, many theories have been developed about what attracts people to one another, when, and why. Although much remains unknown about the dynamics of attraction, some critical factors have been identified. This entry distinguishes factors involved in attraction on the Internet in different kinds of online venues and as compared with face-to-face social settings. It examines the causes and correlates, explores the consequences of attraction for potential and ongoing romantic and platonic virtually formed relationships, and examines the technology and social changes that affect attraction online.

Attraction, Lack of Attraction, and Physical Appearance

In face-to-face interactions, physical appearance has been found to be perhaps the most influential factor in initial attraction. Physical appearance plays an essential role in the attraction process and creates the primary initial “gate” that determines who an individual will approach when in a crowded room of strangers, the friends who will be made, and especially the people who will be approached in hopes of developing a romantic relationship.

Without being aware that they are doing so, people habitually and automatically categorize others by physical features such as ethnicity, style of dressing, and level of physical attractiveness. Research has shown that, based on only seeing a photograph of an individual, there is extremely high consensus about the judgments most people tend to make about the person, across a wide variety of personality measurements, based only on physical appearance. Based solely on facial features, people draw strong conclusions about the other person's levels of intelligence, kindness, sense of humor, motivation, ability to succeed, and other personality traits. The adage “What is beautiful is good” applies to the judgments that people tend to make about others because people tend to assume that those who are more physically attractive also have more positive personality characteristics and are more interesting and attractive in other ways.

Research has shown that first impressions also tend to be lasting impressions and bear on attraction to others over time. First impressions tend to

INTERNET, ATTRACTION ON

What is the basis of attraction? In not very scientific terms, attraction—whether on the Internet or in person—remains largely a mystery. Do opposites

become enduring because people selectively focus on information that confirms rather than disconfirms their initial judgment as they interact with the other person or meet him or her again at a later time. Furthermore, the expectations others form based on their first impression may actually elicit confirmatory behavior from the other person.

Features that are readily perceived, such as physical appearance (attractiveness), an apparent stigma (e.g., obesity), or apparent shyness, thus often serve as gates in face-to-face interactions. These gates often open to admit those who are physically attractive and outgoing, but also often bar the way when the person is less physically attractive or less socially skilled. Attraction on the Internet can have different bases, however. Katelyn McKenna conducted a study that examined determinants of attraction in face-to-face interactions and in Internet interactions by comparing randomly paired participants who interacted face to face to those who interacted via text-only chat on the Internet. The study found that when people interacted on the Internet, in the absence of physical appearance, the quality of the interaction, especially the feelings of similarity, intimacy, and closeness attained, determined liking and attraction. In the face-to-face meetings, however, the quality of the conversation or the similarity of views, interests, and values did not matter to judgments of liking at all, suggesting that physical appearance dominates liking and overwhelms other interpersonally important factors for attraction. Not surprisingly, when participants were asked to freely describe the characteristics of their interaction partner, online partners focused on personality traits, whereas those who met face to face focused largely on physical characteristics, using descriptors such as *tall*, *blonde*, and *well dressed*.

When interactions take place with new online acquaintances in venues where physical appearance is not apparent, such as common interest groups, instant messages (IMs), chat rooms, or the comment sections of blogs, the way an individual looks does not become a barrier to potential relationships. Participants in such venues typically only exchange photographs or get together in person once they have already developed an interest in one another based on their text-based interactions. When a relationship is formed in this way, the level of physical attractiveness does not carry as much

weight when the individuals do finally meet in person. Physical attractiveness, at that point, plays a less influential role in attraction than it would had the participants known immediately what the other looked like when they first became acquainted. Research has also found that the emphasis on physical aspects of self and other is much less when individuals engage in romantic cyberflirting in chat rooms than when flirting in person. Instead, the opinions expressed, and the information about the self that is revealed, form the basis of attraction in such online venues, rather than more superficial features, such as appearance, that drive attraction in face-to-face interactions.

When physical appearance is immediately in evidence on the Internet (such as in dating sites, social networking sites like *MySpace*, and blogs), then the same biases that operate when people meet in person also operate online. As in face-to-face social settings, in online dating venues, when it comes to initial attraction, similarity plays only a minor role compared with the powerful role of physical appearance. Participants in online dating sites use the physical appearance of potential partners as the first criteria and only examine the profiles of those who pass the physical appearance test to discover the potential partner's interests, values, and goals. Indeed, Monica Whitty and Adrian Carr conducted a study that found that more than 85 percent of dating site users would not even consider examining profiles that did not contain a photograph. Other studies have shown that, even after discovering more about the person from the available profile, it is the attraction to the photo that is the deciding motivator to contact or bypass the person. Andrew Fiore and Judith Donath used the number of messages expressing interest that online daters received as a measure of attractiveness and found that men who were older and more educated received the greatest number of responses. For women, however, it was the attractiveness of the photograph along with self-descriptions that did not describe their body type as being "heavy" that received the most responses, regardless of the other information provided in their profiles.

Similarity and Attraction

The Internet has exponentially expanded the potential for individuals to meet others with

important similarities. Common interest groups of every description can be easily found on the Internet where individuals can meet others who share their hobbies, political and religious beliefs, lifestyle preferences, and specific combinations of all these. The Internet can be particularly useful for locating others who share specialized interests (such as an interest in medieval history), who are experiencing similar health or emotional difficulties, or who share aspects of identity that are socially sanctioned and thus are often not readily identifiable in one's physical community. In a longitudinal study of participants taking part in common interest groups online, McKenna found that the relationships, including the romantic relationships formed among members of those groups, were more stable and durable over a 2-year period of time than comparable relationships formed through traditional means. Studies using the same 2-year timeframe, as well as relationships at the same developmental stage at the start of the study (couples who had been "in love" for 3–6 months), have found that the most commonly given reason for the dissolution of romantic relationships formed in traditional settings is that the couples discovered that they did not, after all, share the same interests and values. In contrast, those who met their partner through a common interest group online noted the common interests and values they shared as an important component in the continuation and closeness of their relationship.

Mutual Self-Disclosure and Attraction

It has been well established that people tend to more readily engage in acts of self-disclosure on the Internet than they do in person. Both on the Internet and in person, situation-appropriate self-disclosure fosters feelings of liking and attraction between people. There is a strong tendency for individuals to like and feel attracted to those to whom they self-disclose, to like those who disclose to them, and to disclose more to those they like. Self-disclosure is important to the development of intimacy because it entails being able to express and have accepted one's true personality and inner feelings.

Self-disclosure also has implications for maintaining levels of attraction. In promising relationships in which the partners do not get beyond

superficial levels of self-disclosure, the parties tend to lose the attraction they feel toward one another relatively quickly. When a strong foundation of mutual self-disclosure has been laid, the parties tend to continue to feel deep levels of attraction for one another and to be motivated to maintain the relationship. The tendency to disclose more about oneself, and sooner, to others on the Internet has been linked with feelings of attraction developing more quickly between the parties than typically occurs when new acquaintanceships begin in person. Even with long-standing relationships with family and friends, the heightened self-disclosure that frequently occurs between them through e-mail and IMs has been shown to increase feelings of closeness and to deepen the relationships.

Technological and Social Changes Affecting Attraction on the Internet

When the Internet was in its infancy, the information available and the interactions between individuals were completely textual in nature. Interpersonal attraction at that time was wholly founded on the power of words: through the ideas and thoughts expressed, self-disclosures and aspects of the self that were revealed, and similarities discovered between the writers. It was perceived as being risky to provide identifying information about oneself in any sort of public forum, and thus the majority of users cloaked themselves in anonymity by using nicknames in their interactions online. This anonymity allowed users to be bolder in their self-disclosures than they would be were they identifiable.

Despite that society viewed Internet-initiated relationships with skepticism and, to some extent, disapproval, friendships and romantic relationships between users flourished in this text-only medium. Because of fears surrounding meeting someone only known through the anonymous environment of the Internet and because of forging a relationship entirely through written form, users typically corresponded for an average of 3 months prior to taking the step of meeting one another in person. Internet-initiated relationships became increasingly common and thus increasingly accepted in society.

Technological advances changed the Internet from a text-only media to one that commonly

includes pictures and prerecorded videos, voice chat, and live video feeds. Each of these technological advances has affected attraction processes on the Internet. When pictures and video are initially available, then attraction on the Internet is based on the same determinants of attraction as occurs outside of the Internet.

The technological advances have kept step with the social acceptance of the Internet as a venue for forging and maintaining relationships. Social acceptance and the accompanying reduction in fears surrounding the Internet have decreased the tendency for users to interact anonymously. As users become increasingly identifiable, there is a corresponding chilling effect on the self-disclosures they make with others through the Internet. Social acceptance has also encouraged Internet users to meet one another much more quickly than they did in the past. Dating-site participants exchange an average of only two e-mails before arranging a meeting, for instance. When time and effort have been invested in a relationship (along with an exchange of intimate disclosures), people tend to be more motivated to maintain a positive opinion of the other and to wish to continue that relationship even if, upon meeting, the other's physical and personality attributes are less than expected or optimally desired. Research suggests that the more quickly a new or potential relationship is moved offline, the less chance it stands of the attraction between the parties continuing or the relationship developing further. As the Internet increasingly mirrors communication in the physical world, so too will the patterns and bases of attraction on the Internet.

INTERNET AND SOCIAL CONNECTEDNESS

When Internet-based communication technologies, such as e-mail and chat, became available to the general public in the 1990s, it was widely assumed in both academic and popular literature that these technologies would reduce people's social connectedness. Social connectedness refers to the relationships that people have with others in their environment (e.g., friends, family members, and neighbors). This reduction hypothesis rested on three assumptions: (1) the Internet motivates people to form superficial online relationships with strangers, which are less beneficial than existing, offline relationships; (2) time spent with online strangers occurs at the expense of time spent with existing friends and relationships; and (3) strong, close offline relationships are replaced by weak, distant online relationships, so that the overall quality of people's relationships is reduced.

The reduction hypothesis received considerable empirical support at the early stages of Internet adoption. Several studies conducted in the second

half of the 1990s demonstrated that Internet use significantly reduced people's social connectedness. However, the size of these negative effects was usually small. In such Internet effects studies, social connectedness was operationalized as, for example, the size of people's local network; the time they spent with family members, friends, and neighbors; their perceived social support; or the perceived quality of their relationships with family members and friends.

However, although these reduction effects were demonstrated consistently in the second half of the 1990s, at least two changes in the use of the Internet may render such effects less plausible at the current stage of Internet adoption. First, at the early stages of the Internet, it was hardly possible to maintain one's existing social network on the Internet because the greater part of this network was not yet online. At the time, online contacts were inherently separated from offline contacts. Currently, however, the majority of people in Western countries have access to the Internet. At such high Internet access rates, a reduction effect is less plausible because people have more opportunity to maintain their existing relationships through the Internet than at the early stages of the Internet.

Second, in the past few years, several communication technologies (e.g., IMing and social networking sites) have been developed that encourage users to communicate with existing contacts. Earlier Internet-based communication technologies, such as Multi-User Dungeons (MUDs) and public chat rooms, were primarily used for communication between strangers around certain topics or activities. However, more recent technologies distinguish themselves from previous ones by people's predominant communication with existing relationships.

Against this backdrop, reductive effects of the Internet on people's social connectedness have become less likely. It is no surprise, therefore, that the majority of studies that appeared in the new millennium have found positive effects of different types of online communication on social connectedness. To explain these positive results, scholars have put forward the *stimulation* hypothesis. This hypothesis attributes the positive effects of online communication on social connectedness to enhanced intimate self-disclosure. It is assumed that the reduced auditory and visual cues in online

communication serve as facilitators of intimate online self-disclosure. This Internet-enhanced self-disclosure seems to occur during communication with existing friends, as well as with newly formed relationships. In fact, the stimulation hypothesis is based on three assumptions. First, the Internet's reduced auditory and visual cues encourage people to disclose their inner feelings more easily than in real-life interactions. Second, intimate self-disclosure is an important predictor of reciprocal liking, caring, trust, and, thereby, of the quality of relationships. Third, this Internet-enhanced intimate self-disclosure stimulates relationship formation and maintenance.

Several studies have indeed shown that online communication stimulates intimate online self-disclosure. These studies have also demonstrated that this intimate online self-disclosure promotes online friendship formation, as well as the quality of existing relationships. As a result, the stimulation hypothesis can currently be considered a valid description of the impact of Internet communication on people's social connectedness.

Shortcomings and Future Research

Existing research on the relation between Internet use and social connectedness suffers from several shortcomings. First, in several Internet effects studies, Internet use has often been treated as a one-dimensional concept. These studies only employed a measure of daily or weekly time spent on the Internet and did not distinguish among different types of Internet use, let alone among different types of Internet communication. However, it is widely understood in the media effects literature that different types of media use may result in different outcomes. If the Internet is to influence social connectedness, it will be through its potential to alter the nature of communication when being online. Consequently, not Internet use per se, but specific types of Internet *communication* should be the focus when investigating Internet effects on social connectedness. Some types of online communication technologies (i.e., IMing and e-mail)—in fact those that are predominantly used to maintain one's social network—seem to increase social connectedness. However, communication technologies that are predominantly used

to communicate with strangers (e.g., chat in a public chat room) or more solitary forms of Internet use may have no or even negative effects on social connectedness. Future research should differentiate between types of Internet use and formulate effects hypotheses that are related to the functions that these particular technologies have for their users.
