About the Editors

Harry T. Reis is Professor in the Department of Clinical and Social Sciences in Psychology at the University of Rochester. He was editor of the *Journal of Personality and Social Psychology: Interpersonal and Group Processes* (1986–1990) and is currently editor of *Current Directions in Psychological Science*. He recently completed 10 years as Executive Officer of the Society for Personality and Social Psychology (1995–2004) and has served as member and Chair of the APA Board of Scientific Affairs (2001–2003). He is a past President of the International Association for Relationship Research (2000–2001), a past President of the Society for Personality and Social Psychology (2007), Fellow of the American Psychological Association and the Association for Psychological Science, member of the Board of Directors of the Wynne Center for Family Research, and a former Fulbright Senior Research Fellow (1991). His research concerns mechanisms that regulate interpersonal processes in close relationships.

Susan Sprecher is Professor in the Department of Sociology and Anthropology with a joint appointment in Psychology at Illinois State University. She was the recent editor of *Personal Relationships* (2002–2006). She has also coedited several books or handbooks, most recently *The Handbook of Sexuality and Close Relationships* (2004; Lawrence Erlbaum), *The Handbook of Relationship Initiation* (2008; Taylor & Francis), and *The Science of Compassionate Love* (2009; Blackwell-Wiley). She has served many positions in the International Association for Relationship Research, including most recently as Chair of the Publications Committee. Her research, which has spanned almost 30 years, has focused on many aspects of the social psychology of interpersonal relationships, including love, attraction, exchange and equity, social networks, and sexuality.

Introduction

No attempt to understand behavior, in the individual case or in the collective, will be wholly successful until we understand the close relationships that form the foundation and theme of the human condition.

Ellen Berscheid and Anne Peplau (1983, p. 19)

Although lay people and scholars alike have been interested in human relationships since at least the beginning of recorded history, it is only in the past 3 decades, with the emergence of what has come to be called *Relationship Science*, that systematic attention across diverse disciplines has kindled tremendous growth in research and theory about human relationships. This work takes as its starting point the idea that relationships are fundamental to nearly all domains of human activity, from birth to death. When people participate in healthy, satisfying relationships, they live, work, and learn more effectively. When relationships are distressed or dysfunctional, people are less happy, less healthy, and less productive. Few aspects of human experience have as broad or as deep effects on our lives as relationships do.

When we refer to relationships, we mean the full gamut of human associations in which behavior is influenced by the real or imagined presence of another person with whom one has interacted in the past and expects to interact in the future. This definition includes many different types of associations—friends, lovers, spouses, roommates, teammates, parents and their children, cousins, siblings, acquaintances, neighbors, mates, coworkers, and business associates. Although each of these relationships is unique in one or another respect, they share a common core of principles and processes. Researchers strive to identify both the unique

features and the common elements, with the ultimate goal of explaining parsimoniously and accurately the nature and impact of human relationships. The types of relationships that have received the lion's share of scientific attention are those in which the members are interdependent—that is, frequently, strongly, and diversely influenced by each other—and as a consequence these receive greater coverage in this encyclopedia.

Many of the scientists who have contributed to scientific knowledge about personal relationships over the past several decades are represented as authors in this encyclopedia. They come from many disciplines. Some of the more central disciplines in Relationship Science are psychology, sociology, communication, and family studies, but scholars from anthropology, physiology, neuroscience, history, economics, and legal studies are also involved. Typically, scholars from different disciplines emphasize different aspects of relationships, come from different theoretical backgrounds, use different methods for research, and publish their work in different journals. Despite these differences, they share an interest in advancing understanding of human relationships, both in terms of how they operate and how they influence human activity. This diversity of approaches has enriched Relationship Science, although it also makes the field seem like a sprawling, modern metropolis with many communities, each with its own special character, spread around a common hub. Some leaders in this field, such as the late Harold Kelley, have asked whether the field should become its own discipline. Although the field is not at that stage, many relationship scientists from a variety of disciplines are connected through their association with the professional organization, International Association for Relationship Research (www.iarr.org), which sponsors conferences and two journals that publish scholarship on personal

relationships, *Personal Relationships* and *Journal of Social and Personal Relationships*. Still, most relationship scholars retain their identification with their home disciplines, as evidenced by the fact that relationship research is published in many and diverse journals.

Why an Encyclopedia of Human Relationships?

In a review of the personal relationships field written about 10 years ago, Ellen Berscheid and Harry T. Reis described the field of interpersonal relationships as “one of the most rapidly growing areas of the social and behavioral sciences” (1998, p. 194) and as resembling a “boomtown during the gold rush days of the American west” (p. 257). In the decade or so since then, the boomtown has become, as mentioned above, a sprawling metropolis, suggesting to Michael Carmichael and Rolf Janke at Sage that the time was right for a multi-volume encyclopedia reviewing the field’s extensive set of theories, concepts, and empirical findings about human relationships. Their excitement about the project was infectious, and they easily convinced Reis to be an editor, who in turn, easily convinced Susan Sprecher to join as co-editor. Together, we chose advisory board members with special expertise that we did not have: Rosemary Blieszner, W. Andrew Collins, Patricia Noller, Terri L. Orbuch, Doug K. Snyder, and Anita L. Vangelisti. As a team, we then reached out to hundreds of authors, who also caught the fever.

The Process

Obviously, there was much work behind the scenes to make it possible for you, the reader, to now be browsing through three volumes of up-to-date information about human relationships. (And we encourage browsing!) We considered several options for selecting the list of topics to be included, settling on what might be called the Willie Sutton method. Willie Sutton, a prolific bank robber, was once asked why he robbed banks. He is reputed to have replied, “Because

that’s where the money is.” We too decided to go “where the money is”—that is, we examined leading textbooks and handbooks in the field to see “where the research and theory is.” Letter by letter, we identified the most popular and important topics, eliminating redundancies or idiosyncrasies and adding new headings where we saw gaps or new developments. Later, our superb team of advisory editors helped us refine the list. And much later, authors, too, pointed out omissions. The encyclopedia thus emphasizes those theories and topics that are most commonly studied in the field.

Once we had a near-complete list, we began the task of identifying an author for each entry. We invited accomplished researchers and scholars with expertise on the topics to write the entries. Most accepted our invitations; in fact, some volunteered to write more than one. Many involved coauthors, including their brightest students.

Beginning in October of 2007, drafts of entries began arriving. For months rarely would a day go by that we were not providing feedback on one or more entries. Most of the entries were superbly written by our authors, but in our role as editors, we typically offered suggestions for making the entries even more informative and accessible to the general reader. Fortunately, our team of advisory board members also assisted us in this formidable task. The project moved quickly, thanks to hard-working authors and advisory board members, an excellent staff and Web site at Sage, and our compatible workaholic styles. (There were more than a few “Are you still up?” e-mails.) Now, as the encyclopedia nears completion, in February of 2009, we marvel at the speed with which this project has been accomplished and the breadth of topics represented.

The Audience

In deciding to embark on this project and during the many hours of work that this enterprise took, we never lost sight of you, our audience. We knew our audience would be as diverse as the scientists in the field. We both come from nonacademic families, and we thought about readers who do not have advanced degrees, but will still find their way to these volumes because they are curious about

relationships. We wanted this work to be accessible and of interest to you. We thought about undergraduate and graduate students, who thirst for scientific knowledge about relationships and human behavior; we envisioned you scanning these volumes for ideas to pursue in a class project or thesis. We thought about our colleagues from around the world, with whom we have shared the journey of the scientific pursuit of knowledge about personal relationships. We pictured all of you pulling these volumes off a library shelf over and over again in order to read what an expert has to say about something you have been wondering about, a new idea you want to explore, or to look up further readings. We even thought about the librarians who will order this encyclopedia—perhaps it will be more than a professional tool for you. This volume is for all of you.

Organization of the Entries

Topics are listed in alphabetical order, from A (Abortion) to W (Workplace Relationships); no suitable X-Y-Z topics appeared (although we considered xenophobia, youthfulness, and zoology). Some topics are particularly central and well developed in the literature, and these receive thorough attention in more than one entry. Long entries, approximately 3,000 words in length, represent the most important and well-developed topics in the field, for which extensive and general research and theory exists. These might be considered the bedrock for current understandings of human relationships. Medium-length entries, approximately 2,000 words in length, discuss subjects that have attained significance in the field as core topics. Short entries (1,000 words) describe topics that are relatively new to the field or that are less central to understanding human relationships.

Readers wishing a more reader friendly overview to the encyclopedia, and hence to Relationship Science as a field, will find the Reader's Guide helpful. The Reader's Guide organizes the headwords into the following 18 substantive themes:

- Cognitive Processes in Relationships
- Communication Processes

- Creating and Maintaining Closeness
- The Dark Side of Relationships
- Dating, Courtship, and Marriage
- Emotion Processes in Relationships
- Family
- Friendship and Caregiving in Adulthood
- Health and the Biology of Relationships
- Methods for Studying Relationships
- Personality and Individual Differences
- Prevention and Repair of Relationship Problems
- Psychological Processes
- Sexuality
- Social Context of Relationships
- Social Relations in Childhood and Adolescence
- Theoretical Approaches to Studying Relationships
- Types of Relationships

Each entry is categorized into one or more of the above themes. In addition, each entry includes cross-references at the end, cross-references which allow the reader to easily find other entries covering related material. Readers wanting more in-depth information will also find the Further Reading list provided for each entry to be helpful.

Acknowledgments

A project of this sort does not come off without the assistance of many people. We are indebted to Michael Carmichael, whose infectious enthusiasm we could not resist, and to Rolf Janke, who made it real. Sanford Robinson, our developmental editor, solved innumerable problems and was always encouraging. Leticia Gutierrez and Laura Notton made the Sage Reference Tracking system work for us, without which this encyclopedia would have been a logistic nightmare. Kate Schroeder and three copyeditors—Robin Gold, Heather Jefferson, and Renee Willers—did their magic in turning our word-processing files into books.

Just as the theme of this encyclopedia is human relationships, so we both have benefitted throughout this project from relationships both professional and personal. As for the former,

our advisory board—Rosemary Blieszner, W. Andrew Collins, Patricia Noller, Terri L. Orbuch, Doug K. Snyder, and Anita L. Vangelisti—was a steady source of brainstorming, sound advice, and confidence as the project progressed. We could not have done it without them! As for the latter, Harry is grateful to Gus and Margot, his parents, for making relationships so compelling, and to Ellen and Lianna for their patience, support, and above all else, love. Susan wants to acknowledge the support, past and present, of Charles, Abigail (and partner Alex), Katherine, and Samuel, and of Milton and Shirley, her parents. Finally, we both are grateful for our friendships with colleagues that blend the personal

and professional. Most of them are in these volumes with us.

Harry T. Reis

Susan Sprecher

A

ABORTION

Abortion, the medical or surgical termination of a pregnancy, is one of the oldest, most commonly practiced, and most controversial medical procedures performed in the United States. Pregnancy and abortion are intertwined with close relationships; pregnancy is of course the natural result of a sexual relationship (brief or long lasting) between a female and a male partner. The decision to deliver versus terminate a pregnancy is often based on relationship issues, and close others frequently are involved in the decision process. Support and/or conflict with close others influence women's coping and adaptation following abortion. And delivering versus terminating a pregnancy can affect close relationships. Following is a brief discussion of each of these issues.

Role of Close Relationships in the Abortion Decision

The majority of abortions are of unintended pregnancies. Approximately half of American women will face an unintended pregnancy, and nearly half of those pregnancies will be resolved through abortion. Hence, abortion cannot be separated from the precipitating event of unplanned pregnancy. The small percentage of abortions that are of planned pregnancies usually occur because of fetal anomalies or risks to the woman's health.

Relationship concerns, including the desire to avoid single parenthood, problems within an ongoing relationship, and concerns for or responsibility to others are among the most frequent reasons cited for terminating an unintended pregnancy. Motivations for abortion differ among different subgroups of women. Women at particularly high risk for unintended pregnancy and for abortion tend to be young, unmarried, poor, and women of color. The majority of women obtaining abortions already have one or more children. Adult mothers are more likely than younger women or nonmothers to cite responsibilities to other children as reasons for obtaining an abortion. In contrast, younger women and nonmothers are more likely to cite partner issues and immaturity.

The lack of a stable relationship with a male partner is a primary reason women cite for deciding to abort a pregnancy. Some women believe that it is inappropriate or too difficult emotionally or financially to raise a child without a father. Women also cite problems within an ongoing relationship as major reasons for choosing abortion, including poor quality relationships and concerns about whether the relationship would survive childbearing (or additional childrearing). Women who have unintended pregnancies and women who have abortions are disproportionately likely to have been the victims of intimate partner violence in their current or former relationships. Possible explanations for this include (a) situational and personal risk factors (e.g., poverty, substance abuse, poor coping skills) that put women at risk of unintended pregnancy and abortion also put

women at risk of entering into abusive relationships, (b) women in abusive relationships may be less able to regulate their fertility because they are subordinate to their partners, (c) women in abusive relationships who become pregnant may be more likely to abort the pregnancy rather than have children (or more children) with abusive partners, (d) unwanted pregnancy may be seen as an obstacle to leaving an ongoing abusive relationship, and (e) women in abusive relationships may be more likely to feel pressured by their partners to have an abortion. With regard to this last possibility, however, a national study revealed that less than 1 percent of women cite coercion from others as a major reason for their abortion.

Most women who obtain abortions inform their conception partner of their pregnancy, and most women report that the decision to abort was either entirely their own decision or was shared equally with their conception partner. Women in the United States are not legally required to inform or seek the consent of their conception partner. The U.S. Supreme Court ruled in *Planned Parenthood v. Casey* (1992) that requiring a woman seeking abortion to notify her husband creates an “undue burden” on her constitutional rights. Women are more likely to inform partners who they perceive as likely to support rather than to oppose their decision. Data on male partners’ influence in the abortion decision, however, is sparse. The little research that exists suggests that in deciding whether to deliver versus abort a pregnancy, male partners consider similar factors as do women, such as current family size and the ideal conditions of childrearing.

Parents also can play an important role in the abortion decision, especially for minors. In 1976 the U.S. Supreme Court decided in *Planned Parenthood of Central Missouri v. Danforth* that states may infringe on the constitutional right of minors to privacy given a “significant state interest” in doing so. By 1997, a majority of the U.S. states had enacted statutes requiring minors to either involve parents in abortion decisions (by notifying them of the abortion or by obtaining their consent) or to petition a judge for an exception (commonly referred to as judicial bypass).

The Supreme Court based their decision to constrain minors’ ability to obtain abortion on several assumptions. First, that minors are especially at risk for negative psychological responses following

abortion and that such consequences would be less of an issue if they carried a pregnancy to term; second, that minors are too immature to make a sound, well-reasoned decision without the benefit of input from an adult; and third, that parental consultation is desirable and in the best interests of the minor and her family. Scientific evidence in support of these three assumptions, however, is weak.

Critics of consent laws argue that minors who come from supportive families will consult with parents by choice and that girls who come from unsupportive, dysfunctional, or violent homes will not benefit from the forced disclosure of their pregnancy. Critics further argue that consent laws create delays in seeking care, thereby increasing the rate of later term abortions and teen parenthood. Even in the absence of parental involvement laws, a significant percent of minors do consult with at least one parent prior to making an abortion decision. A minor will be less likely to consult with parents for several reasons: She fears her parents will be hurt, unsympathetic, or even violent in response; she lives independently or already has children; she has experienced a chaotic home environment characterized by substance abuse, violence, or sexual abuse; or she suspects her parents will oppose her decision or force her into a specific undesired pregnancy resolution.

Close Relationships and Adjustment After Abortion

Close others, such as the conception partner, parents, and friends, can be both a significant source of support and a significant source of strain in coping with the stress associated with an unintended pregnancy and abortion. They can provide instrumental support, for example, by providing money to pay for the abortion or transportation to and from the clinic. They can also provide emotional support before and after the abortion.

The perceived reactions of close others are important factors in women’s postabortion adjustment. Women who perceive high levels of social support from close others are more satisfied with their abortion decision and have better mental health postabortion than women who perceive less social support from close others. Also, the more women perceive close others as supportive of their

decision, the more they believe they will be able to cope with the abortion. These positive coping appraisals, in turn, are associated with reduced postabortion distress. A longitudinal study revealed that women who had lower expectations for their ability to cope prior to their abortion also were more likely to report seeking social support from others to deal with emotions experienced in the 2 years following their abortion. Support seeking, in turn, was associated with reduced postabortion distress controlling for preabortion distress.

Perceived social conflict with close others surrounding an abortion can be a significant source of additional stress. The more women who abort perceive pressure from others to terminate (or not to terminate) a pregnancy and the more social conflict they perceive from partners, family, and/or friends around the abortion, the more likely they are to experience negative psychological reactions postabortion.

Fear of being rejected by others because of an abortion is a significant concern of many women who have an abortion. The current sociopolitical climate of the United States stigmatizes women who have abortions. One study found that approximately 50 percent of women who had an abortion felt that others would look down on them if they knew, and the more women felt stigmatized, the more they felt they needed to keep their abortion a secret from family and friends. Concealing an abortion from friends and family may provide some immediate interpersonal benefits. It may allow a woman to avoid social conflict and the disapproval of others, both of which can be detrimental to mental health. It also may preserve important relationships and social networks that could be threatened if the abortion was known.

Concealing an abortion, however, can also lead women to engage in maladaptive coping strategies, setting into motion cognitive and emotional processes that exacerbate psychological distress over time. One longitudinal study showed that the more women perceived a need to keep their abortion secret from family or friends, the more they reported trying to suppress thoughts of their abortion. Ironically, this attempt to suppress led to more intrusive thoughts of the abortion. Both suppression and intrusion, in turn, were associated with greater psychological distress 2 years postabortion, controlling for preabortion distress. Secrecy also

was associated with less disclosure of abortion-related feelings. Expressing feelings about emotion-provoking events can be a way of understanding and coming to terms with those events, as long as the others to whom one expresses are supportive. One study found that women who perceived their conception partners to be less than completely supportive were more distressed following their abortion than either women who did not inform their conception partners or women who told their partners and perceived them as completely supportive.

Impact of Abortion on Close Relationships

Very little research has examined how abortion affects close relationships. An adequate understanding of this question must consider the relative impact of abortion compared with its alternatives (motherhood or adoption). It must also take into account the nature and quality of the prepregnancy relationship. Because an unstable or unsatisfactory relationship is often a reason for abortion, rates of relationship dissolution after an abortion may reflect preexisting problems. The percentage of women expected to break up with their partner over the course of a year, irrespective of a pregnancy or abortion, also must be considered.

One prospective study compared the relationship quality of 92 women who were seeking abortion to the relationship quality of a comparison group of 92 demographically matched women who were not pregnant and did not desire a child. Both groups were in stable relationships of similar duration at the time of the first interview. Prior to the abortion, the relationships of the abortion group were of poorer quality (more conflict, less affection, less trust) than the control group. One year postabortion, however, there were no differences between the abortion and control group in relationship quality, mutual trust, satisfaction with sex life, or relationship separations. By the second interview, a similar percentage of relationships had ended in both groups (about 22 percent).

ABUSE AND VIOLENCE IN RELATIONSHIPS

The terms *abuse*, *violence*, and *aggression* tend to be used interchangeably, and such abuse can be physical or nonphysical, although violence usually refers only to physical abuse. The term *psychological abuse* tends to refer to abuse that is verbal or emotional, or even economic. In this entry, abuse is first discussed in terms of different behaviors, and then it is discussed in terms of Michael Johnson's typology based on both the behavior and the person who is involved in perpetrating the abuse. The focus then shifts to causes and predictors of abuse and violence, the types of relationships in which abuse and violence are most likely to occur, the consequences of partner violence for victims and for children who witness the violence,

and the ways victims tend to cope with violence. Although violence can be an issue in a number of relationships, including parent–child and sibling relationships, the focus in this article is on couple violence.

Types of Abusive Behavior

Physical abuse can range from pushing and shoving, hitting and punching, to using or threatening to use a weapon such as a knife or gun. Battering tends to involve the more extreme forms of physical abuse mentioned above, as well as beating-up the victim. Verbal abuse can involve name-calling, insults, put-downs (behaviors that most couples are likely to use from time to time during conflict), or more extreme emotional abuse that attempts to destroy the confidence and self-esteem of the victim. Statements such as “You’ll never amount to anything,” “You’d be nothing without me,” “You’re useless” fall into this category. Perpetrators may also seek to separate the victim from support groups of family and friends and may threaten extreme consequences if the victim reports the abuse. Another tactic of extreme abusers is to threaten to harm children or pets or to damage precious possessions if the victim does not comply. Some abusers use economic abuse such as denying access to money as a means of control and as a way of ensuring victims have less access to a range of resources and hence a great difficulty leaving the relationship.

Whether abuse is primarily perpetrated by men or women has been a contentious issue over more than 25 years. Some argue that men are the main perpetrators of violence in couple relationships, and women are violent only when defending themselves against male brutality. Others argue that males and females are equally violent because that is what most studies show. Michael Johnson's typology, however, has to some extent helped to clarify the issues. He argues that there are different types of abuse; his main two categories are intimate terrorism and situational couple violence.

According to Johnson, which type of violence is found depends on the type of sample being studied. Intimate terrorism is more likely to be found in clinical or refuge samples (those seeking refuge

in a shelter). This form of violence is seen as one tactic in a general pattern of control, is more likely to escalate over time and involve serious injury, occurs more frequently than situational couple violence, and is mostly perpetrated by men, although it is sometimes perpetrated by women. Intimate terrorism tends to be based on a belief in male privilege and superiority: "I am the boss in this house," "What I say goes and you'd better do it." It can involve physical attacks, coercion and threats, emotional abuse, intimidation, isolation, and economic abuse.

Some research suggests that there are two types of intimate terrorists: dependent and antisocial. The dependent group tends to be jealous and possessive and use violence to deal with fear that the partner might leave. The antisocial group is more generally violent in a range of contexts, both familial and nonfamilial, mostly in order to dominate. They are more likely than the dependent group to be involved in substance abuse and criminal behavior.

Situational couple violence, on the other hand, accounts for almost all violence in community samples, is less likely to involve severe violence or to escalate over time, generally involves both members of the couple, and is not connected to a general pattern of control. Many of the studies finding equal levels of violence by men and women are based on community samples. This type of violence often occurs as the consequence of an argument between partners.

Although both members of couples are likely to be involved in violence, because of sex differences in size and strength, women tend to be more vulnerable to injury. The important difference between intimate terrorism and situational couple violence is that intimate terrorism is part of a general pattern of control of the partner whereas situational couple violence comes out of a particular event such as an argument and can reflect poor conflict resolution skills.

Another type of violence is included in the typology: violent resistance, which is mostly perpetrated by women to defend themselves from intimate terrorists. Whether women's violence is mainly about resistance, however, is a contentious issue. Although women may try this form of resistance, they generally develop a pattern of not resisting because of fear for their lives. In extreme situations, they may

even resort to killing their violent partner. Unfortunately, most research does not distinguish between different types of violence and does not make clear which type of violence is being studied.

Couple Violence

Some writers argue that the main reason for couple violence is the patriarchal nature of society and the gendered nature of roles. They argue that male dominance at the societal level is the most important contributor to wife abuse at the personal level. Others, however, argue that although patriarchy may contribute to violence against women, there are multiple causes of violence. Violence can be a result of individual psychopathology such as psychopathy or lack of impulse control or other individual factors such as attachment insecurity or rejection sensitivity.

The communication patterns established by the couple can also increase the possibility of violence, although it is important to see such patterns as a couple issue rather than blaming the victim. In other words, violence can be seen as a product of the way couples have set up their relationships. For example, there is evidence that couples in violent relationships tend to be highly sensitive to each other's negativity. Problems with children can also lead to couple violence, especially if the perpetrator sees the partner as responsible for the problems (e.g., "She's too soft with him, that's the real problem in this family").

Abuse and violence can be predicted by relational factors and by individual characteristics of the husband and of the wife. For example, in a large study conducted in New Zealand where all families with a baby born at a particular time were recruited, violence against the wife was predicted by all three factors. Violence was most likely to occur if the partners were under 20, unmarried, or had been married only a short time before the birth; the pregnancy was unplanned; their educational level was low; and they did not attend church. Because this study involved a community sample, the violence was most likely to be situational couple violence, although some intimate terrorists were probably included.

There is also evidence that male perpetrators of violence tend to differ from other males in the following ways: They have longer periods of unemployment, have lower levels of education, have less social support, use a variety of drugs, are more severely depressed, and are more likely to have an antisocial personality and to perpetrate violence outside the family. Individuals involved in severe partner violence tend to be similar to those described above but more likely to be alcohol dependent and to score higher on criminality scales. Alcohol use is strongly related to abuse and violence, particularly if the husband is drinking heavily before marriage. If the wife also has a drinking problem, the risk of violence tends to increase.

Types of Relationships

Dating and Courtship

Abuse and violence can occur in a range of relationship types from dating relationships to marriage and lesbian relationships. Abuse and violence occur in dating relationships, and around a third of couples report violence before marriage. About one third of high school and college students report experiencing violence in their dating relationships, although some studies show lower levels of violence. Even severe violence or battering seems to begin during courtship.

Abuse and violence are more likely to occur when couples engage in verbal aggression, the male partner lacks social support, and the female partner uses negative coping strategies such as avoidance and distancing. One study of undergraduate students found 12 different risk factors for assaulting a partner. These factors included problems with anger management, jealousy, and communication; a history of neglect or sexual abuse; negative attributions about the partner; and approval of violence as an interpersonal tactic. As can be seen, some of these factors belong to individuals and some are characteristic of relationships. Violence seems to increase with the length of relationships but decrease as commitment increases, with commitment tending to promote positive relational strategies. Thus violence is less likely in long-term committed relationships.

Cohabiting or de Facto Relationships

Although it has been claimed that the marriage license is a “hitting license,” there is evidence for more violence in cohabiting, de facto, or common law relationships than in marital relationships. This finding is likely to be related to lower levels of commitment in cohabiting relationships than marital relationships. In addition, women in cohabiting relationships are more likely to be killed by an intimate partner than are those in marital relationships (e.g., 6 times more likely in Canada and 9 times more likely in the United States).

In a large Canadian study aimed at increasing understanding of women’s heightened risk of violence in common-law unions, researchers included both selection variables and relationship variables. Selection variables are those that individuals bring with them into cohabitation (such as education, employment history, and previous relationships), and relationship variables are about the relationship itself (such as jealousy, social isolation, and dominance). The researchers found significantly higher levels of violence in cohabiting than in marital relationships. In addition, despite the increase in cohabitation in the culture, selection variables were more important than relationship variables in predicting violence against women; it seems that the type of person who cohabits rather than the couple’s relationship predicts the greater likelihood of violence. These researchers note that not all potentially relevant variables were included in this study, and a more comprehensive study might find variables such as commitment and relationship satisfaction as important predictors of violence in cohabiting relationships. It is also important to note that relationship variables included in this study tended to have an impact on violence for both cohabiters and for those married.

Marriage

In the first year of marriage, almost a third of husbands and wives report at least one act of aggression by husbands, and more than a quarter of couples report multiple episodes of violence and/or severe violence. About half that number report single episodes of minor violence during that first year. Younger couples and those where at least one member belongs to a minority group are more likely to report aggressive behavior. Conflict

is also an important predictor of aggressive behavior, with husband and wife anger expression and husband problem solving being positively related to marital aggression and wife problem solving being negatively related to marital aggression. It seems likely that the problem solving by husbands referred to in this study tends to involve dominating rather than facilitative behaviors.

Couples in violent relationships have been studied in terms of their interaction patterns while discussing an issue in their marriage. Both husbands and wives in relationships involving physical aggression have been found to enact fewer positive behaviors than other couples and to respond in ways likely to increase the partner's anger. They are also likely to become involved in cycles of attack and defense. They have fewer problem-solving skills, and have difficulty discussing a marital problem without withdrawing and experiencing a sense of despair. They tend to be highly aggressive to one another and to engage in criticism, disagreement, and put-downs at a high rate and engage in lower levels of such positive behaviors as approval, smiling, and paraphrasing.

Lesbian and Gay Relationships

Studies have shown that violence in homosexual relationships occurs as frequently as in heterosexual relationships and is equally severe and that rates of psychological abuse tend to exceed rates of physical and sexual abuse. In addition, power and control tend to be major sources of conflict. One very powerful control tactic used in these relationships is threatening to "out" the partner to their family or at work. Another is to threaten a partner that they could lose their children if outed because of their sexual orientation. Problems can also be caused by their lack of support from friend, families, and society.

Coping With Partner Violence

There are basically two ways to cope with violent relationships: One is to negotiate an end to the violence, and the other is to leave the relationship. For example, in one study, 75 percent of victims were no longer in a violent relationship after 2.5 years. About 40 percent had left the relationship, and 30 percent had negotiated an end to the violence.

Of course, partners must improve their problem solving and communication skills to successfully maintain a violence-free relationship.

Concerns are frequently expressed about women who stay in abusive relationships, particularly when battering is involved. The evidence suggests, however, that about twice as many wives leave as stay in abusive relationships. Nevertheless, those who stay are a concern, particularly if trapped by partners who manipulate their personal, moral, and structural commitments to the relationship. In one study, whereas wives in distressed nonviolent relationships reported that they stayed in the relationship in the hope that it would improve, those in violent relationships tended to focus on their love for their partner.

Leaving seems to involve a two-stage process. The first stage involves victims working out whether they will be better off if they leave than if they stay, and the second involves assessing their confidence in their ability to go through with their decision. This latter decision may be particularly difficult for those whose self-esteem has been destroyed through years of physical or verbal abuse. If they have also been victims of economic abuse, or have no resources such as money or a car, leaving may be particularly difficult.

Consequences of Partner Violence

For Victims

Researchers tend to agree that the consequences of partner violence are much more serious for female than for male victims. Because men tend to be bigger and heavier than women, the chances of serious injury are much greater for women than for men. Given the heavy controlling tactics often used by perpetrators, women are also likely to suffer more serious psychological effects such as depression, anxiety, and lowered self-esteem. Some have even been treated for post-traumatic stress disorder. Men who are abused may be doubly stigmatized because of the shame involved in admitting to abuse by a woman.

For Children Who Witness Violence

Children who witness violence between their parents are affected in terms of both their behavior

and their psychological adjustment. Their behavior is likely to be more aggressive than that of other children given the strong model of violence in the family. Psychological effects include anxiety, depression, lower self-esteem, and a diminished sense of security in the family. Long-term effects include depression, lower self-esteem, and lower levels of social competence.

Intergenerational Transmission

The term *intergenerational transmission* refers to the likelihood that those who grow up in violent homes are more likely to perpetrate violence against a partner. Studies have shown that males growing up in violent homes are significantly more likely to be violent toward partners than males growing up in nonviolent homes. In addition, experiencing abuse in the home is more strongly related to becoming a victim than witnessing abuse is, and this effect tends to be stronger for females. Not surprisingly, these effects tend to be stronger in clinical than community samples, given that the violence is likely to be more severe in these samples and more likely to be perpetrated by males.

Conclusion

Couple violence is a serious problem in many societies and causes a range of physical and psychological problems in the victims. Children who witness violence are likely to have poorer psychological adjustment and are more likely to become perpetrators of violence in their own close relationships. The causes of couple violence are complex and multilevel, and although patriarchy may play a role, a range of other individual, couple, and family factors also need to be considered. Couple violence occurs in a variety of relationships including dating, courtship, cohabitation, marriage, and gay relationships, with evidence for more violence in cohabiting relationships.

ABUSED WOMEN REMAINING IN RELATIONSHIPS

A woman's decision to stay in or leave an abusive relationship is complex. It can be influenced by the type of abuse the woman has experienced (psychological, physical, sexual, or various combinations of these types), the characteristics of the abuse she has experienced (frequency, intensity, injuries sustained, and whether or not it is escalating or diminishing over time), the characteristics of the abuser (remorse shown, degree of alcohol involvement, amount of emotional instability, degree to which his threats are perceived as putting her in mortal danger, his level of psychopathy, and whether he is violent both inside and outside of the intimate partner relationship), and the characteristics of the victim (education level, religiosity, mental health concerns, income generating capability, responsibility for mothering children, perceived options, level of fear, the degree of hopelessness, and her sense of feeling love toward the perpetrator). Characteristics of the interpersonal relationship (prior separations, married versus cohabitating or dating) and social context in which the relationship is embedded (police involvement, access to help, external support,

cultural pressure to remain married) may also play a role in how the abuse is perceived and whether or not the woman chooses to stay in the relationship over time or to end it. Each of these aspects of the stay–leave decision is briefly discussed below. Each of these elements feeds into two central questions that are at the essence of the stay–leave decision facing abused women. According to Pamela Choice and Leanne K. Lamke in an influential 1997 article, these two questions are as follows: “Will I be better off?” and “Can I do it?”

Characteristics of the Abuse Experienced

The type of abuse experienced by the woman may differentially impact her and may affect her help-seeking behavior. It may also play a role in a woman’s decision about whether to stay in or leave an abusive relationship. Recent research indicates that acts of physical violence and psychological aggression between intimate partners are relatively common among dating, cohabitating, and married couples. Sexual violence occurs less frequently and may be the most taboo type of violence to disclose to others. Experiencing psychological abuse may, at times, impede the woman’s leaving the relationship, as it can reduce the victim’s sense of self-efficacy and confidence while increasing her feelings of self-blame. Women are less likely to leave an abusive relationship if they have been repeatedly told, and they, in turn, come to believe, that they cannot leave or will not make it without their abuser or that no one else will ever love them or care for them. In contrast, experiencing physical violence alone or in conjunction with other types of abuse has been shown to have the strongest relationship to leaving the abusive relationship, but relatively little is known about the experience of sexual violence within an ongoing intimate relationship and how this impacts remaining in the relationship over time.

Women also consider characteristics of the violence they are experiencing when they are considering whether to leave or stay in the abusive relationship. Women are more likely to leave relationships in which the violence has led to a physical injury, and although some studies have suggested that women tend to underestimate the risk of injury or death from their violent intimate partner, they rarely have been shown to overestimate the

risks associated with remaining in the relationship. Women consider aspects of the violence in their risk appraisals, and women who perceive the violence as escalating in severity and frequency have been shown to be more likely to intend to leave the abusive relationship permanently.

Characteristics of the Abuse Perpetrator

Recent research has repeatedly asserted that there are subtypes of violent perpetrators who may have substantially different characteristics. Many studies have shown that common couple violence may describe the majority of intimate relationships in which violence has occurred. Both men and women have been shown to perpetrate common couple violence. Generally, this type of violence is related to relationship distress and poor conflict management techniques. Bidirectional common couple violence is the most common pattern. The violence perpetrated in these types of relationships tends to be less severe and more episodic in nature than the violence perpetrated by other types of offenders and in other types of relationships. Perpetrators of common couple violence have typically been shown not to suffer from severe personality disturbance and severe alcohol problems; in addition, they do not usually perpetrate violence outside of their intimate relationship. Because of the lower severity and greater likelihood of mutuality, women involved in these types of violent relationships may be less likely to leave than women who are being abused by a violent man who is psychopathic or suffers from various kinds of emotional problems including depression, alcoholism, or borderline personality disorder. Consistent with this supposition, it has been shown by Karen Pape and Ileana Arias in 2000 that women’s intentions to permanently end their violent relationships increase if they perceive that their abuser is malicious, selfish, and blameworthy. On the other hand, evidence suggests that leaving an abusive relationship can be a particularly dangerous time and may be more so with malicious, controlling, emotionally volatile, or selfish perpetrators. Many abused women have to consider the reality that leaving their abusive partner may not end the abuse or even lessen it. Leaving may even end in the murder of the woman and/or her children.

Characteristics of the Abused Woman

Characteristics of the abused woman may also influence her stay–leave decision. Younger women have been shown to be more likely to leave an abusive relationship than older women. Other factors associated with the victim may include the environment in which the abused woman was raised. Specifically, approximately half of all abused women report having experienced some type of childhood abuse, with two thirds reporting having experienced feeling unloved or rejected as children. It is possible that a history of childhood abuse impacts the stay–leave decision in a number of ways. Women who grow up in abusive homes may view their partner’s abusive behavior as more normative and less pathological than women who had not previously been exposed to family violence. A childhood abuse history may also negatively impact the woman’s self-esteem and confidence in her ability to successfully leave the relationship. Experiencing child abuse has also been associated with greater levels of depression and trauma symptoms in adult women, effects which may in turn make ending a currently abusive situation more difficult or may increase the woman’s feelings of self-blame for the intimate partner abuse.

Similar psychological symptoms that are known to be consequences of experiencing current abuse may also impact the stay–leave decision. These symptoms would include greater experience of trauma-related symptoms, increased intensity and severity of depressive symptoms, and a reduced sense of self-efficacy as a consequence of experiencing the relationship abuse. Women coping with these psychological sequelae may have a more difficult time believing that they can leave, seeking external support and resources for the separation or contemplating caring for themselves or their children in the absence of the intimate relationship.

Women also report staying in abusive relationships because of their religious or social role beliefs, such as holding the belief that it is their wifely duty to stay, that women are supposed to be able to please a man or make a marriage last, or that divorce is against their religion. Abused women also report a number of fears about leaving, including the fear of embarrassment, the fear of loss (e.g., the potential relationship, financial

loss, etc.), the fear of looking and/or feeling like a failure, and the fear of retaliation on the part of their partner. Fear of financial loss may be of particular importance in the decision-making process; women who have successfully left an abusive relationship are more likely to have left an unemployed than an employed intimate partner. Abused women also report worrying a great deal over what will happen to their children should they leave. On the other side of the equation, women who experience feelings of love, commitment, or hope for change on the part of their partner may be less likely to leave their abusive relationship than women who no longer experience positive feelings even intermittently in the relationship.

Characteristics of the Interpersonal Relationship

Both structural and dynamic characteristics of the abusive relationship may impact the stay–leave decision. Financially, it may be easier to leave a dating relationship than a relationship that involves cohabiting, marriage, or shared household expenses. In addition, legal involvement is required for dissolving a marital relationship; this level of disentanglement is likely to be even more difficult when there are children involved. Many abused women weigh the costs and benefits of leaving the relationship in relation to the emotional and physical health of their children, as well as in relation to themselves. Relationships characterized by reciprocal violence may be emotionally more difficult to leave than those characterized by unidirectional violence. Women may also be abused by other women in the context of a same-sex relationship. Factors associated with leaving lesbian relationships have been understudied.

Leaving More Than Once and External Support

Deciding whether to stay or leave an abusive relationship involves the weighing of a variety of costs against a number of benefits as well as a realistic consideration of whether the woman feels capable of instigating the leaving process. This decision is more likely to be a process than a one-time event, as it is common for women to leave the same abusive

relationship more than once. In fact, research has shown that those who successfully leave are more likely to have tried leaving the relationship at least once before.

Overall, deciding to leave involves repeatedly making the decision that the benefits of leaving outweigh the costs of leaving and, simultaneously, that costs of staying outweigh the benefits of staying. Evidence suggests that the process of making this decision often begins after a particular episode of abuse has occurred. Women are more likely to stay engaged in the decision-making process if they have the perception that the abuse is escalating and their lives may be in danger. The first stage of the process involves deciding whether or not to disclose the episode of abuse to someone, and if so, to whom. Abused women who are able to secure and utilize safety and housing for their children, who have access to transportation, and who have some assurance of financial support are the most likely to attempt to leave. Social support from family, friends, and the community (e.g., police, judges, health care providers) also plays a vital and ongoing role in the decision process. Leaving an abusive relationship has been associated with successfully obtaining a restraining order against the abuser and with talking with a health care provider about the abuse. Conversely, women who seek external support and are denied it have been shown to be even more likely to remain in the abusive relationship.

ACCOMMODATION

Even in the best relationships, close partners do not always treat each other with care and kindness. In interdependent relationships, it is inevitable that partners will sometimes behave in a manner that is potentially destructive to the relationship. For example, a partner might be rude or insulting, may neglect to spend promised time with the other partner, or may otherwise disregard the other partner's needs. When faced with destructive partner behaviors, the other partner has a choice: to respond in kind or to accommodate. *Accommodation* refers to responding to a partner's destructive act by inhibiting the impulse to reciprocate with another destructive act and instead behave in a constructive manner. For instance, if Bill criticizes Mary's taste in music, Mary could accommodate by choosing not to criticize Bill in return and instead calmly initiate discussion of their difference of opinion or simply let the moment pass without comment. This entry explains the concept of accommodation, the factors that may motivate interdependent partners to accommodate, and how accommodation may benefit close relationships.

Caryl Rusbult and her colleagues first identified accommodation as an important part of relationship interdependence. They defined accommodation in terms of the exit-voice-loyalty-neglect (EVLN) typology of responses to dissatisfaction in relationships. According to this typology, responses to dissatisfaction vary along two dimensions: Responses are constructive or destructive to the relationship, and responses actively or passively address the problem at hand. There are four categories of response: *Exit* involves actively harming

a relationship (e.g., yelling at the partner, leaving the relationship), *voice* involves actively attempting to improve the situation (e.g., discussing the problem, seeking advice from a therapist), *loyalty* involves passively waiting for the situation to improve (e.g., turning the other cheek in the face of criticism, hoping or praying for improvement), and *neglect* involves passively letting the relationship deteriorate (e.g., avoiding discussion of problems, ignoring the partner). Thus, accommodation can be defined as responding to a partner's exit or neglect behavior with voice or loyalty.

Furthermore, Rusbult proposed that when a partner acts in a destructive manner, the individual's first impulse is to reciprocate as a means of self-protection. For example, when Bill criticizes Mary, she may feel insulted and demeaned. If Mary's response is based on her immediate self-interest, she is likely to retaliate to regain her dignity or to seek revenge. However, such retaliation would likely escalate the conflict, potentially harming the relationship. If Mary forgoes her self-interest and instead acts in a conciliatory manner, their relationship may benefit. Thus, Mary faces a dilemma: to enact a self-interested response that is potentially destructive to the relationship or to enact a personally costly, relationship-oriented constructive response. *Interdependence theory* distinguishes between the given situation and the effective situation in interdependence dilemmas such as this one. The *given situation* involves an individual's self-centered, gut-level preferences that are based on the immediate, personal outcomes that he or she may obtain from an interaction. If Mary's behavior is guided solely by the given situation, then she is likely to retaliate. However, individuals often do not act on their given preferences alone; instead, they take into consideration broader concerns, such as their long-term goals for the relationship. If Mary considers that she is committed to her relationship with Bill and wants it to endure, then retaliation—which may damage the relationship—no longer seems desirable. By considering broader issues, Mary has transformed the given situation into the *effective situation*, and it is the effective situation that directly guides her behavior. Research has provided empirical evidence that this sort of *transformation of motivation* underlies the accommodation process.

Researchers have examined several relationship-specific factors that may promote prorelationship

transformation of motivation that results in accommodation. Results indicate that the investment model variables of relationship satisfaction and investment size are positively associated with accommodative tendencies, whereas quality of alternatives to the relationship is negatively associated with accommodation. Level of commitment to the relationship repeatedly has been found to be a highly reliable predictor of accommodation—the more committed partners are to each other, the more likely they are to forgo self-interest and accommodate for the sake of the relationship. Furthermore, research suggests that commitment largely mediates the association between the other investment model variables and accommodation.

Researchers have examined several personality variables that are predictive of accommodation. For example, people who are *psychologically feminine*—that is, they fit traditional feminine sex roles—are more likely to accommodate. To the degree that individuals are able to take their partner's perspective in a situation, they are likely to accommodate. People who exhibit greater self-control are more likely to accommodate, as are those who have greater self-respect. There is mixed empirical evidence that individuals with a secure attachment style are more likely to accommodate than those with an insecure attachment style. Although most research suggests that security is an important predictor of accommodation, some research suggests that security may be unrelated to accommodative tendencies. Recently, researchers also have found mixed evidence that socially oriented values, such as collectivism (i.e., concern for the welfare of one's community), promote accommodation.

Given that accommodation has been characterized as a relationship maintenance behavior, researchers also have examined how accommodative behavior may benefit a relationship. Researchers have found repeatedly that accommodation is positively associated with general relationship health. More specifically, researchers have found that accommodation may promote trust between relationship partners. For instance, if Bill recognizes that Mary is willing to forgo self-interest, overlook his criticism, and engage in prorelationship behavior instead, then he may come to trust that she cares about him and their relationship. Furthermore, accommodation is associated with persistence in relationships; in particular, longer

lasting relationships are characterized by high, mutual levels of accommodation between partners. Thus, although accommodation involves some immediate personal cost, the payoff of long-term relationship health may be worth it.

ACCOUNTS

Whoever takes the time to stop and listen to the conversations around them will come to recognize how often people describe their lives and relationships in story-like form. At the coffee shop, friends swap stories with each other about major problems with spouses, mothers-in-law, and nasty neighbors. At the lunch table, teens take turns telling stories about their most recent relationship breakups or who said what to whom at the last dance party. These accounts or stories all represent ways in which people organize views of themselves, of others, of their social networks, and of their relationships. They contain rich and detailed information about the nature and dynamics of a present

relationship and of preexisting normative beliefs and rules about what makes a relationship and how to behave appropriately in that relationship.

Sometimes others ask for these accounts, as when a friend asks how one first met one's boyfriend, girlfriend, spouse, or best friend. But other times, people spontaneously tell others a story about a specific relationship. Either way, people tell stories about their relationships because these accounts help to make sense of those connections, sometimes for their own benefit and sometimes for the benefit of those selected as their audience. This entry discusses the historical context of the concept of accounts and the usefulness of accounts-as-stories. Today, many relationship scholars are turning directly to the voices and stories of individuals for insight and information about relationship experiences.

Historical Context

Accounts as Justifications or Excuses

The concept of accounts historically had its development and central beginnings in the field of sociology. The writings of sociologists such as Harold Garfinkel, Erving Goffman, and Marvin Scott and Stanford Lyman led the early theoretical work, which was focused on understanding how people present or excuse themselves to others when their interaction or relationship is disrupted or problematic. The emphasis was on people trying to communicate or account for the negative situation or social predicament in a way that maintains the interaction or relationship. In general, this body of work examined three questions: (1) What is the content of these accounts? (2) Under what conditions (and relationships) do people present these accounts? (3) What factors influence whether an audience will accept the accounts of others? This line of research continues to elaborate and refine the various types of justifications and excuses that people communicate to others and the consequences of these specific justifications.

Accounts as Story-Like Constructions

In the field of interpersonal relationships, current views equate the concept of accounts with more common terms, stories, and narratives.

These story-like concepts emphasize first-person interpretations or explanations about why and how relationship events happen (e.g., initiation of sexuality in a relationship, pregnancy or birth of a child, divorce, financial hardship). These relationship accounts are told to others for feedback and support. In contrast to the earlier sociological concepts, this current notion of accounts-as-stories is more social psychological in nature and focus in that it embodies a wider variety of situations in which accounts are presented to others. Current work emphasizes accounts as cognitive processes by which individuals create, explain, and organize meaning about the social world.

Current viewpoints claim that accounts not only protect the self and maintain interaction but also give people a greater sense of control in their relationships, help people cope with stressful relationship events, provide a greater sense of hope and understanding for the future, and establish order and closure to their relationships. Accounts contain recollections of the events in one's relationships, including plot, story line, affect, and attributions. These accounts-as-stories are seen as fluid interpretations or meanings of relationships, meanings which are constantly being modified and updated as individuals obtain feedback from others. Current work on accounts also integrates research and theory from three general perspectives: attribution theory (causal explanations for relationship events and behaviors), ethnography (construction of meaning to make sense of relationships), and impression management theory (creation of desired impressions).

Current Themes in Research

A growing body of research indicates that there are multiple functions and beneficial consequences of relationship accounts to people's lives and relationships. Sometimes researchers ask people to account for a relationship event so that they can study these stories; other times people just spontaneously tell a story in a variety of forms (e.g., autobiography, folktales, mythology, organizational report). Regardless of whether they are solicited or spontaneous, examination of this scholarship illuminates several themes.

Coping With Stressful Events

An expanding and significant body of literature demonstrates that accounts allow individuals to cope with major stressors or traumas within their relationships. These stressful events can include a courtship that is filled with obstacles, betrayals within romantic relationships or friendships, and divorce or the termination of a relationship. Findings in this research demonstrate that when people experience a traumatic relationship event, they develop an account to understand what happened and why. This account helps individuals explain to others and to themselves why the event happened and provides a greater sense of control over what may seem otherwise incoherent and confusing. John Harvey and Terri Orbuch argue that when individuals try to understand their past through the use of accounts, they also can feel a sense of mastery over the past, a feeling which contributes to present well-being. Indeed, studies show that accounts are positively linked to the physical and mental health of individuals following a stressful relationship event. For example, research demonstrates that when sexual assault survivors engage in account making (e.g., tell their stories to friends, family, and therapists; journaling; expressing story through art or music), they are better able to cope with their trauma than survivors who repress or do not account for their experience.

One interesting finding is that relaying these accounts to others, especially a confidant who gives a positive and empathic response, plays an important role in coping with major relationship transitions and traumas, regardless of whether or not the account is wholly accurate. Once the events begin to make sense to the individual, the events can be better dealt with, even if these accounts do not mirror reality. Evidence also suggests that the interaction-social process of confiding a relationship account to others provides some degree of closure, which also may have positive consequences for well-being.

Relationship Meanings and Processes

Because accounts contain rich and detailed information about relationships, both in content and storytelling style, scholars can use these first-person interpretations to obtain information about relational beliefs or values (e.g., working models of

friendships, reasons for divorce) and about specific relational processes and concepts (e.g., commitment, marital quality, conflict, family traditions, and values). Some researchers claim that since accounts allow individuals to have a voice in the reports about their own relationships, these stories reveal distinctive information beyond what can be assessed with standard quantitative survey measures.

Many relationship scholars focus on relationship accounts as a technique to gain a better understanding of the meaning individuals find in their personal relationships and in the unfolding of relational processes over time. For example, the particular themes or issues that emerge in the account give information about how the individual thinks relationships should work (e.g., “My marriage should get better over time”) or serve as a warning signal of a relationship in trouble (e.g., jealousy, anger). Accounts also can reflect specific interactive processes and emotions. Studies show that the stories told by happy couples differ in many ways from those told by unhappy couples (e.g., happy couples typically develop their story in a much more collaborative rather than conflictive manner).

In addition, relationship accounts allow researchers to understand the self and the development of specific identities over time (past, current, and future). For example, research indicates that story-telling in families and couples helps to construct and strengthen a joint identity (e.g., family identity), which then leads to an increased sense of clarity and satisfaction for the couple and other family members. Family stories (e.g., about grandparents who survived the war and came to the United States with nothing but the clothes on their back) told and retold to other family members both construct and reflect the values and goals of a family (e.g., “This family works hard and survives hardship”).

Social Context of Account Making

Another research theme has been to examine the context within which accounts are developed and shared with others. In these studies, there is recognition that individuals construct meanings of their relationships based on the social context of that relationship and the individual. This research has focused on such questions as are there in certain periods of life (e.g., major transitions, retirement),

events, or relationship stages (e.g., initiation, termination) when the development of a relationship account is intensified, when a fuller account is presented to others, or when people are more likely to disclose their accounts to others.

One very important context that has received considerable recent attention is the cultural or group context within which accounts and relationships are embedded. Relationships are constructed and embedded in group norms and expectations, which help determine the meanings of various relationship processes, such as conflict, parenthood, or decisions regarding the division of labor. Three important group contexts for relationship accounts are race/ethnicity, gender, and social class. Research findings demonstrate that although there are similarities in the courtship and marriage stories presented by Black and White couples, there are important differences as well. For example, religion plays a stronger role in the way Black American couples, compared to White American couples, talk about their marriage. Also, at least in the early years of marriage, White Americans are more likely than Black Americans to talk about their feelings about something as a couple and to collaborate with their spouse in the story-telling process. In contrast, Black American couples are more likely to provide accounts as individuals involved in the marital relationship.

Relationship Therapy

The concept of accounts-as-stories also has played an important role in relationship therapy. Research evidence suggests that storytelling in the therapeutic environment is effective for dealing with emotional stress and reducing negative emotions. In particular, for couples who come to therapy to work on relationship issues, storytelling has been shown to be effective in reducing negative affect experienced about their relationship. These stories also help therapists and couples gain a handle on couple dynamics (e.g., how one spouse deals or speaks to the other spouse), insight which can reveal problems that need attention or encourage new ways of thinking about problems. Stories also elicit positive experiences and feelings of love, which couples may have forgotten ever existed in their relationship. In counseling, these stories strengthen the quality of the interpersonal relationship that is being worked

on or alternatively allow couples to separate in a way that facilitates future well-being and joint parenting obligations.

ACCURACY IN COMMUNICATION

Accuracy in communication encompasses how well communicators create verbal and nonverbal messages that are understood by others and how well those messages are recognized, comprehended, recalled, and interpreted. Accuracy refers to an objectively quantifiable metric by which the communication that is sent or received can be compared against some objective standard, or what is often referred to as *ground truth*. For example, if a sender expresses authentic anger,

the recipient is accurate to the extent that he or she classifies the expression as anger rather than, say, love or surprise. This entry describes those lines of research specifically conducted under the rubric of general *encoding* and *decoding* accuracy. Accuracy can be divided into expression or encoding accuracy, which concerns message production, and judgment or decoding accuracy (also sometimes referred to as sensitivity), which concerns message reception. Accuracy in sending and receiving messages depends on a variety of factors called moderating variables, which include sex or gender, personality, and individual social skills, among other moderating factors. This entry divides moderators between (a) communication and relationship variables such as presence of interaction, expression type, and communication channel and (b) individual difference variables such as gender and personality.

In some very important respects, people are accurate in their communication. When communicating with others, people make sense of situations quickly and with limited information. People interact on a daily basis with others whom they do not know very well or have just met, and they are able to converse and accomplish tasks together with ease. Additionally, people are able to anticipate how well-known others will respond and what they will say in a particular situation. Although the ability to read others varies based on a host of communication and individual difference factors, accuracy in communication and perceptions is frequent and evident in everyday interactions.

Nonetheless, in other ways, communication is very inaccurate. A common axiom in communication textbooks is that the message sent is not the message received. For example, research indicates that people tend to use their own thoughts and feelings to make sense of others' experiences, and they often overestimate the similarity between their own and others' reactions. Every textbook on communication fundamentals enumerates the source, message, channel, receiver, relationship, and context factors that affect the accuracy with which messages are exchanged. Finally, there is evidence that in ongoing relationships, people may not always strive for accuracy; inaccuracy may actually help sustain the relationship. Thus, inaccuracy must be addressed side by side with accuracy.

Encoding Accuracy

Four types of encoding accuracy can be distinguished. Two—social expressiveness and social control—refer to verbal aspects of message encoding (i.e., what people say), and two—emotional expressiveness and emotional control—refer to nonverbal aspects of message encoding (i.e., how they use body language when communicating). The expressive forms of verbal and nonverbal encoding apply to more spontaneous expressions of emotions, feelings, and mood states. Accurate encoders are ones whose verbal statements and nonverbal expressions are correctly identified by message recipients or observers. The control aspects of message encoding refer to the ability to regulate, mask, or modify verbal statements and nonverbal displays so as to maximize intentional, socially appropriate, or desired communication and to minimize unintentional, inappropriate, or undesired expressions. Accurate encoders are ones whose deliberate verbal and nonverbal expressions are correctly identified by message recipients.

Research on encoding accuracy is sparser than on decoding accuracy. Relevant veins of encoding research cover emotional expressions, deception, and moderators of encoding accuracy. Encoding research primarily examines nonverbal behavior, as compared to decoding research, which includes both verbal and nonverbal behavior.

Emotional Expression Accuracy

An emotion is accurately encoded to the extent that it is legible and readily identified by receivers or observers. Most of the work on encoding accuracy has focused on facial and vocal expressions rather than on other encoding modalities such as touch. Accuracy is a function of which emotion is being expressed. Readable facial and vocal expressions of anger, nervousness, and sadness appear to be easier to produce than complex affects like pride, sympathy, love, or jealousy. Whether an expression is posed or spontaneous, pleasant or unpleasant, or highly or moderately intense also influence accuracy.

Deception Encoding Accuracy

Deception, broadly construed, refers to messages sent with intent to mislead another. It may include not only outright lies but other forms of deceit such as equivocation, exaggeration, concealment, omission, and evasion. In the case of deception, accuracy in discerning the truth on the part of receivers means the sender has failed to accurately convey his or her intended message. Thus, inaccuracy on the part of receivers corresponds to success, or accuracy, on the part of senders.

Those who are best at fooling their targets include those who score high on the encoding dimensions of social skills (social expressivity, emotional expressivity, social control, emotional control), especially social (verbal) control and emotional (nonverbal) expressivity. Further, those who can convey an honest-appearing, credible demeanor—sometimes referred to as demeanor bias—are the most successful at evading detection and reducing accuracy of recipients.

Communication-Related Moderators of Encoding Accuracy

Perhaps the most influential factor moderating encoding accuracy is the presence of interaction itself. Research on interaction often utilizes a social relations model in which individuals interact with multiple partners so that factors related to individual differences and the impact of interacting with a particular partner can be sorted out. This research shows that accuracy does not simply result from the skills of the individual communicators. Some dyads were systematically more or less accurate than the individual skills of expressers or perceivers would predict, a finding which suggests that something happens within that specific interaction to allow communicators to more accurately assess one another.

A second plausible moderator is communication channel, or the vehicle used to convey the message, such as the voice or body or written text. Research on the relative merits of different channels for transmitting messages has focused more on which channels people rely on than on how accurate they are, but common wisdom suggests that having multiple channels with which to send

redundant and complementary information is superior to single channels. Also more beneficial is the use of interactive communication forms such as Internet chat or the telephone that permit corrective feedback. The impact of interaction and feedback on encoding accuracy is particularly evident in research on deception. Deceivers are better able to enact a more natural looking demeanor (e.g., fluent speech, appropriate content management) in interactive, dialogic situations, and this ability is especially true when an individual is interacting with a partner who displays an involved and pleasant communication style.

Individual Difference Moderators of Encoding Accuracy

Research has shown that effects of sender expressivity are reliable and large in magnitude, indicating significant individual variability. Among the specific individual variables that affect expressive accuracy are gender, age, social skills, and personality. Considerable research shows that women are more accurate than men at displaying both spontaneous and deliberate nonverbal expressions, and the differences are noticeable. This gender difference among male and female adults is not found reliably among children, suggesting that it is more attributable to social learning than to biology. Female superiority also varies by emotion and channel. Facial pleasantness, disgust, distress, fear, and anger are easier for women to produce than other basic emotions and complex affects; for men, only guilt is slightly easier to produce than other emotions. Female superiority in expressive accuracy is virtually nonexistent for vocal expressions.

Possible sources of differences among men and women in accuracy that have been proposed include evolutionary differentiation, different degrees of specialization in the brain, differences linked to power and domination of women by men, and differences in male versus female social roles. Comprehensive reviews of the research literature indicate that power and dominance explanations have less empirical support than sociocultural ones related to expectations, social norms, and roles and related affective experiences.

Other individual factors moderating encoding accuracy are social skills and personality. That is, some people have trait-like qualities that make their communication more readable than others. Emotionally expressive women and men who are good social actors are more proficient at emotional encoding. More generally, individuals who score high on social competence, expressivity, dominance, extraversion, and/or exhibitionism and low on neuroticism are more accurate in transmitting intended emotions than their less socially skilled, inexpressive, or shy counterparts.

Decoding Accuracy

Decoding accuracy addresses how well individuals recognize, comprehend, and interpret communication from others. Research on decoding accuracy, broadly construed, includes work that examines nonverbal and interpersonal sensitivity, emotional intelligence, and empathic accuracy. Overall, this research highlights the importance of decoding abilities in successfully managing interaction and developing relationships.

Emotion Identification Accuracy

Research indicates that individuals are able to recognize a variety of emotions (including happiness, fear, and surprise) quickly with relatively high levels of accuracy. Moreover, decoding emotion seems to involve automatic forms of processing, with accuracy increasing only slightly when perceivers are given time to reflect on the potential meaning of the emotion displayed.

That being said, some expressions are easier to decode than others. Primary emotions such as happiness, anger, and surprise are typically easier to recognize than blends of emotion such as contempt or shame. This tendency makes sense because blends incorporate cues from several different emotion displays and because emotions such as contempt or shame are often tied to social norms about expected behavior and appropriate emotional response. Pleasant facial expressions are typically easier for people to decode than unpleasant expressions (e.g., disgust, anger, or sadness). Skill in decoding pleasant expressions extends to

specific cues like smiling, and individuals are quite good at distinguishing between fake and genuine smiles. People are able to decode pleasant emotions at low levels of intensity while decoding accuracy for unpleasant emotions increases as the intensity of the displayed emotion increases. It is interesting that individuals are better able to decode emotions typically thought of as more socially appropriate. Much has been made of the importance of decoding accuracy as a type of survival skill, which would be particularly important with regard to negative emotional states of others; however, research suggests that people are good at recognizing the positive emotional displays that occur more regularly in interaction.

Empathic Accuracy

Decoding accuracy, however, involves more than simply recognizing or labeling the emotional expression of another. It also involves the ability to accurately take the perspective of a partner in interaction. Empathic accuracy refers to the extent to which an individual is able to accurately infer the thoughts and feelings of another. Although individuals show high levels of accuracy in some situations (especially with others they know well), inferring another's thoughts and feelings is a complex task fraught with error. Some researchers have noted the difficulty of taking another's perspective, a difficulty which is sometimes referred to as the empathy gap. This empathy gap occurs because accuracy requires that one take into account all aspect of another's perspective, including his or her emotional state. This gap seems to remain even when individuals share similar life experiences. For instance, research has shown that having similar life experiences, such as new motherhood, alcoholism, or parental divorce, did not increase empathic accuracy when assessing a partner's thoughts and feelings during interaction.

Deception Detection Accuracy

A significant body of research has addressed accuracy in detecting deception. Comprehensive studies of this demonstrate that detection accuracy averages 54 percent. This figure, which is just above the level of accuracy that would occur by

chance (50 percent) if one were to rate another's communication as either truth or lie, implies a poor rate of detection. However, other research using continuous measures reveals a greater level of sensitivity to deception. People are better able to recognize when something is amiss or suspicious than they are to identify deception *per se*.

Communication-Related Moderators of Decoding Accuracy

In interaction, individuals decode another's communication utilizing a number of different verbal and nonverbal cues as well as contextual information. Most of the research on decoding emotions has utilized posed expressions, often providing only limited nonverbal cues such as facial expressions. Such studies strip away emotional expressions of cues that communicators would typically use in making sense of an emotion display. This difference is important because natural interaction typically requires individuals to make sense of a wide range of cues and codes of information. Additionally, one thing that individuals are sensitive to is the consistency between verbal and nonverbal messages. Decoders show higher accuracy when channel consistency is present than when one channel contradicts another, such as when the words are encouraging but the voice and face show negative emotions.

As regards channels for judging emotions, individuals are more likely to accurately recognize emotions when they have access to a full range of verbal and nonverbal cues and when asked to judge emotion from a limited set of static cues. However, the reverse is true when decoding deception. Accuracy is higher (and better than chance) when judging vocal than facial expressions, and having visual cues available hampers judgmental accuracy, possibly because humans are easily misled by visual cues.

Research on empathic accuracy has shown that verbal content is a primary source of accuracy in assessing a partner's emotional state. However, highest accuracy obtains when participants have access to verbal and nonverbal cues and when participants assess both thoughts and feelings (rather than just one), possibly because perceivers utilize different types of cues for judging thoughts and

feelings. When making judgments about an interaction partner's thoughts, perceivers utilize verbal cues, but they rely more heavily on visual nonverbal cues when making judgments about feelings. Nonverbal cues are important to accuracy, but they may be most central when verbal cues are not informative or when there is discrepancy between verbal and nonverbal.

An additional influence on accuracy is the nature of the interpersonal relationship between communicators. It makes sense that individuals who know one another well would be better able to read one another, and some research supports this view. But this is not always the case. For instance, although relational partners tend to think they can accurately detect one another's deception, they typically cannot. Although relationships afford individuals the opportunity to develop sophisticated bases of knowledge from which they can draw to facilitate communication accuracy, constant accuracy in communication between relational partners may be threatening if accuracy reveals a partner's doubts or negative feelings about the relationship. When dealing with benign, nonthreatening information, accuracy should be beneficial to relationships. However, in the case of threatening relational information—such as information that a partner is attracted to someone else—inaccuracy helps to maintain stability of the relationship. This motivated inaccuracy is thought to have protective effects and may actually buffer individuals by lessening their awareness of relational threats or by limiting the impact of negative emotional contagion.

Individual Difference Moderators of Decoding Accuracy

Sociodemographic moderators of decoding accuracy include gender, age, and culture. Women are generally better at decoding than men, which may result from socialization practices but may also reflect power differences between men and women. There is some evidence that women demonstrate higher empathic accuracy than men, but a number of studies show inconsistency in men's and women's empathic accuracy. When men and women are equally motivated to infer a partner's thoughts and feelings, gender differences disappear.

Adults are typically more accurate at decoding emotion in interaction than children. This accuracy relates largely to the ability of adults to use more sophisticated perspective-taking skills in determining the meaning of messages. Interestingly, culture also plays a role in decoding emotion and nonverbal cues. For example, individuals more accurately identify emotions displayed by in-group members, possibly because cultures differ in how they conceptualize different emotions and in cultural norms of expressivity, sometimes called *display rules*. These differences shape what decoders expect when emotions are displayed.

Personality also moderates social sensitivity and accuracy. For instance, individuals who are higher in the "need to belong" are more accurate in assessing vocal and facial emotions and show greater empathic accuracy. Additionally, individuals who are more sociable, independent, and psychologically flexible tend to demonstrate greater decoding accuracy.

Work on individual differences in deception detection accuracy has proven controversial. Although some have proposed that there are individuals who are particularly gifted at detection of deception, the majority of the research concludes that there is very little variability among individuals; that is, people are uniformly poor in their detection accuracy. The occasional findings of personality differences do not hold up taken as a whole. However, individuals do differ in the extent to which they view others as truthful and credible. Factors influencing this variability in judgment warrant further examination.

ACQUAINTANCE PROCESS

All sorts and varieties of relationships can emerge from the point at which two people initially become acquainted. After meeting, no two relationships follow the same course of development. Certain commonalities, however, make up what is known about the path of acquaintanceship. The *acquaintance process* describes the initial conditions at work when two strangers meet, the forces and motivations that cause one person to be

chosen as an acquaintance or interaction partner over another, and the variables that contribute to the development of relationships after meeting.

Because acquaintance is less a concrete phenomenon and more a broad set of events and variables, it can be argued that much of relationship science is concerned, directly or indirectly, with how people negotiate the acquaintance process. Understanding how pairs of strangers initially meet and develop patterns of mutual interdependence, all during the course of frequent interaction, is fundamental to understanding later relationship maturation, maintenance, and potential deterioration. The current entry has two major thrusts. First, it will review the initial conditions in place when dyads begin to traverse the acquaintance process. Second, this entry will describe how relationships develop after the acquaintance process has been set in motion.

Setting the Stage for Relationship Development

Conditions for Meeting

In order for two previously unacquainted individuals to meet, at least one of them must first pay attention to the other. Because the world is filled with millions of bits of information, people must be selective in choosing where to focus their attention. In the social world, people who appear unfamiliar and unexpected more easily grab other people's attention. This tendency is important because it induces effort to determine whether the unusual individual is a potential friend or romantic partner, whether the individual presents a threat, or whether the individual is innocuous. People also tend to pay attention to those who appear important or attractive. If a stranger at a party appears to have high status, the likelihood of noticing the person increases—a necessary prerequisite for meeting. The stranger may not become an acquaintance, but the initial condition necessary for affiliation—attention—has been met.

Initiating acquaintance may not always involve choice. There may be other reasons to interact. For example, in situations such as assigned work groups, narrow hallways, and one-on-one meetings, people must interact to accomplish their goals. Scientists label situations containing these strong forces as *closed fields*. Even speed-dating

events consist of a series of closed field interactions that require no initiation to affiliate with multiple available partners, although individuals do decide whether to continue interacting with those they meet during the event. In contrast, situations in which options are available and interaction must be initiated are known as *open fields*. Open fields are exemplified by environments like parties and nightclubs, as well as more common encounters, such as deciding whether to approach a new coworker to discuss plans for the upcoming weekend or whether to strike up a conversation with a stranger about a shared interest in the slogan on his or her t-shirt. These examples all require initiation of acquaintanceship with desirable people among a host of alternatives.

Who Likes Whom?

Attraction is defined as an evaluation of liking for another person, coupled with a tendency to approach the person. Attraction principles apply to all kinds of relationships, romantic and non-romantic. A common assumption is that in open fields, people notice and seek out those whom they find attractive in some way. There is ample evidence to support the idea. Research has identified a number of factors that can cause one person to stand out from others and foster attraction between two people.

The Nature of the Open Field

Physical distance is an important factor in open field settings. All other things being equal, people are more likely to be attracted to others who are within reasonable physical proximity. Thus, those who share dorm hallways, sit in the same row of a classroom, share neighboring offices, or live next door are more likely to become friends than those who do not share proximal space. For example, in one study, police cadets in training were asked to name their best friend in the class. Cadets who sat close were more likely to be best friends than cadets who sat far away. Proximity contributes to attraction by providing individuals with repeated opportunities to engage in enjoyable interactions, which are rewarding and motivate future interactions.

Even if the physical distance between two people is great, the ease with which a person can

be reached represents another form of proximity. Advances in social technology affect the probability of interaction with or attraction to others who are not physically nearby. Cell phones, social networking Web sites (e.g., *MySpace*, *Facebook*), Internet communication (e.g., *Skype*, videoconferencing), and massive online multiplayer environments (e.g., *World of Warcraft*, *Second Life*) are all examples of social technologies that increase the ease with which strangers can meet and develop a relationship.

The Nature of the Self and the Acquaintance

Another set of variables that influence attraction concern the association between an individual's qualities and those of the person being considered for interaction. In general, people tend to like those who seem familiar to them. Familiarity may occur simply from mere exposure. For example, when students in a lecture class were asked to rate the attractiveness of a woman who had sat inauspiciously in the class 0, 5, 10, or 15 times, none of the students reported knowing the woman was in the class. Regardless, the greater the number of classes she had attended, the more attractive she was rated by students in the class.

The degree to which another person is similar to oneself is also an important determinant of attraction. People tend to like those who have similar attitudes and values. One reason why similarity is a strong predictor of attraction is that similar people are more likely to confirm one's beliefs about the world. Belief confirmation improves self-esteem and helps people make sense of the world. Furthermore, knowing that another person is similar to oneself increases the odds that the other person will reciprocate liking, further fueling mutual attraction. An important exception to the similarity-attraction principle is that when individuals expect to be liked by another, similarity matters less than if such an expectation is not already in place upon first meeting.

Finally, physical attractiveness predicts attraction. Those who are deemed beautiful by society are more appealing interaction partners than those deemed less physically attractive, especially, but not exclusively, in potential dating contexts. Romantic relationships tend to be composed of partners of roughly equal attractiveness. This so-called

matching hypothesis is explained as follows: In the process of acquiring mates, highly attractive people tend to be sought out by other highly attractive people whereas less attractive people tend to be avoided by them. The result is that the most attractive people end up with similar others, and less attractive people settle for each other. Another reason that the matching hypothesis works is that society has standards that dictate who is acceptable to whom, and one's field of eligibles tends to be composed of people of comparable beauty.

Other Motives for Acquaintanceship

Although attraction is a powerful predictor of interaction, there are other motives that help to determine when and with whom interaction occurs. Sometimes people affiliate with others to reap the benefits of being liked without actually liking the person back. This phenomenon is labeled *ingratiation*. Ingratiation often occurs when there is a status difference between two people. Associating with superior others confers a competitive advantage to the ingratiation in competitive situations. For example, employees may attempt to ingratiate themselves with a boss to get a promotion, earn praise, or try to stand out from other employees. However, it is not necessary for the employee to like the boss in return. A potential risk of ingratiation is that other people, including the one to whom the ingratiation is being directed, may look down on the tactic.

Another motive for interaction is the desire to gain information and operate effectively in the world. This approach, called *uncertainty reduction*, indicates that individuals pursue interaction with others under two conditions. When highly emotional, people seek out others to evaluate the appropriateness of their feelings, particularly others who may face the same stimulus (e.g., an illness). This sort of social comparison helps people understand their feelings, fulfilling the primary motive, but it also fosters affiliation and strengthens bonds between people. Second, in established relationships, attitude dissimilarity may be problematic because partners often need to make joint decisions and cooperate. Thus, all other things being equal, disagreement with a close partner can make it harder to successfully accomplish various tasks and goals.

Sometimes people are motivated to not interact with desirable and attractive others. Fear of rejection—fear that one's liking for another person will not be reciprocated—is a common motive for avoiding interaction with an attractive or high status acquaintance. When fear of rejection is high, people may not pursue relationships with those they find to be the most attractive; instead, they lower their standards for a potential mate. When initiating relationships, people with a strong fear of rejection tend to feel vulnerable and behave in a more guarded manner, which often inhibits relationship development. Low self-esteem, social anxiety, and shyness are associated with fear of rejection, and people with chronic fears of rejection have difficulty initiating and maintaining relationships.

Relationship Development

Not all dyads, even if mutually attracted, will continue from first encounters through a process of acquaintanceship. Nevertheless, without attraction, it is unlikely that interaction will persist when there are desirable and available alternatives, at least in open fields. For this reason, scientists have designated attraction the gatekeeper to relationship development. Once the gates are open, however, different processes guide people who were once strangers down the path of acquaintanceship and, potentially, acquaintances down the path to friendship or intimacy. The principles of relationship development are important second steps in the acquaintance process.

Self-Disclosure

Few relationships develop without both parties learning progressively more about each other. Though some of what is learned can be obtained through observation, what others choose to reveal is especially important for relationship development. *Self-disclosure*, the process of revealing personal information to others, has received a great deal of research attention. Although theories diverge in just how important self-disclosure is to relationship development, almost all theories agree that it is important.

For example, social penetration theory suggests that increasing levels of self-disclosure are the hallmark of relationship development. As two people

become increasingly close, they reveal more and more aspects of themselves, and the amount and depth of information that they divulge on any one aspect also increases. According to the theory, closeness will not increase without associated increases in self-disclosure. Furthermore, knowing the depth and breadth of two people's self-disclosures will indicate roughly how deep into the acquaintance process they are. Self-disclosure and closeness are tightly interwoven.

Other theories, such as the interpersonal process theory of intimacy, acknowledge self-disclosure but differentiate *emotional disclosure*, self-disclosure that reveals emotional content, from *factual disclosure*, which tends to be more informational in nature. Emotional disclosure tends to foster relationship development to a greater degree than factual disclosure. More important, though, is *perceived responsiveness* to emotional self-disclosure. Perceived responsiveness is defined as the feeling that when one's needs are expressed, the listener communicates understanding, support, and care. For example, one friend Tracy may reveal her innermost secrets to the other friend Kari, but if Kari does not respond appropriately, by communicating understanding, validation, and care, then Tracy is likely to feel vulnerable and exposed. Relationship development is likely to be stunted as Tracy shifts her focus from the relationship back onto herself. Therefore, self-disclosure per se does not build relationships, but rather the quality of the interaction that takes place around the disclosure is central to relationship development.

Despite differences between theories in the role of self-disclosure in relationship development, one set of consistent findings is the association between self-disclosure and liking. First, people tend to disclose to those they like. Second, people who self-disclose tend to be liked better than those who do not. Third, people tend to like those they disclose to. These principles hold true for both men and women during the acquaintance process, though some sex differences appear consistent. For example, women tend to self-disclose more than men on average. And in same-sex dyads or groups, men tend to disclose more factual information while women tend to disclose more emotional content. Self-disclosure is important for relationship development, but it is also related to liking and preferences for same- or opposite-sex

affiliation, which is a useful predictor of attraction early in the acquaintance process.

Trust

As closeness increases and the personal value placed on a relationship increases, vulnerability increases. Individuals who are close share private details with each other, rely on each other to meet their needs, and often put the good of the relationship ahead of personal goals. Although such closeness may certainly be satisfying, it is also associated with the potential to be hurt or exploited by one's partner. Trust is a process intended to protect against the vulnerability that arises during relationship development. One important theory of trust conceptualizes it as (a) the increased ability to predict a partner's behaviors, (b) the increased likelihood of judging a partner as dependable in addition to predictable, and (c) faith that a partner's dependability will persist through difficulty. Such experiences give individuals confidence that a partner will be responsive to their needs and will not take advantage of the growing interdependence in the relationship.

Trust is thought to be relationship-specific more than a personal trait and is usually mutual. In other words, although trust is directed toward the person in a relationship, the trust is about the relationship. Caring about another, feeling committed, and relationship longevity are positively associated with greater trust. In a large sample of individuals involved in a romantic relationship, those in new relationships reported the least amount of trust, followed by exclusive dating partners, engaged or cohabiting couples, and finally newlyweds and married intimates. Thus, experiences that strengthen the relational bond also confirm the partner's trustworthiness.

Adoption of Communal Norms

Norms governing equality in relationships differ as a function of a relationship's progress through the acquaintance process. Between strangers, acquaintances, neighbors, and casual friends, it is implicitly assumed that favors be returned quickly and be of equal value to the original favor. Between closer friends, romantic partners, and family members, however, returning a favor of equal value is not a pressing concern because it is implicitly assumed

that both parties are equally concerned with each other's welfare. The former sets of rules are called *exchange norms*; the latter, *communal norms*.

Generally, people of lesser acquaintance follow exchange norms. As relationships develop, people begin to follow communal norms. People tend to follow these rules without deliberate thought, but they can become keenly aware when a communal or exchange rule has been violated. Asking a girlfriend in the morning for the 20 dollars that was loaned last night would violate a communal norm and is likely to be perceived as rude. Alternatively, adopting communal norms too early in a relationship (such as not repaying a loan from one's neighbor quickly enough) is usually equally inappropriate. Generally, people are skilled at detecting those who violate rules of exchange.

Sometimes usage of exchange and communal norms can be manipulated to stunt or accelerate relationship development. Adopting communal norms early in the acquaintance process can signal a desire to increase closeness. In one experiment, college men paid more attention to an attractive woman's needs during a laboratory task when she was labeled as single and new to campus than did men who interacted with the same woman when she was labeled as married and living off-campus. In both cases, the woman was a stranger, but communal norms were adopted when the possibility of a future relationship was apparent.

Conclusion

The acquaintance process is vital to the formation and development of all varieties of interpersonal relationships, from acquaintances to close friends to romantic partners. These processes occur across the various domains of human lives and activities, as well as across the life span, allowing individuals to distinguish between others with whom a deeper relationship is desired from those failing to pique one's interest. Acquaintance processes highlight rewarding interaction partners who may help satisfy an individual's goals, thus motivating effort to further the relationship. Without the steps outlined here, human relationships would be nothing more than momentary, often trivial interactions between two people currently occupying the same space.

ADOLESCENCE, ROMANTIC RELATIONSHIPS IN

Romantic relationships during adolescence, as in other life periods, are mutually acknowledged ongoing voluntary interactions. Compared to other relationships with peers, romantic ones typically have a distinctive intensity, commonly marked by expressions of affection and current or anticipated sexual behavior. This definition applies to same-gender, as well as mixed-gender, dyadic relationships. The term *romantic experiences* refers to a larger category of activities and cognitions that do not involve direct experiences with a romantic partner but that are relevant to individual and social development during adolescence. This category includes fantasies and one-sided attractions or crushes, as well as interactions with potential romantic partners or brief romantic encounters (e.g., hooking up).

Developmental changes in romantic experiences occur during the adolescent years (commonly, ages 12–18) and extend well into the 20s (now commonly called emerging adulthood). These normative patterns, however, mask considerable variability. Although most studies have been conducted in industrialized societies, most typically in North America, romantic experiences during adolescence are determined largely by the cultural context. Same-gender romantic experiences, though rarely studied before adulthood, clearly overlap with those of heterosexual youth but also involve somewhat different interpersonal processes and contextual factors.

Although conceptualizations of adolescent romantic relationships have been remarkably consistent across existing studies, no standard operational definitions exist, nor has the broader domain of romantic experiences been well specified. Researchers typically have asked participants if they have a romantic relationship, and the participants decide on the basis of their own definition. A brief description is sometimes provided (e.g., “When you like a guy [or girl] and he [or she] likes you back”) for clarification. Researchers often also specify a minimum duration (e.g., at least a month long) in an effort to narrow the criteria. Differences in definition affect estimates of

the frequency and duration of romantic relationships and perhaps even the findings that are obtained.

The sections that follow outline common features of adolescent romantic experiences and research findings regarding changes in romantic experiences and behaviors from ages 12 to 18.

Incidence and Significance of Romantic Relationships for Adolescents

Romantic experiences are hallmarks of adolescent development. More than half of U.S. adolescents report having had a special romantic relationship in the past 18 months. High school students commonly report more frequent interactions with romantic partners than with parents, siblings, or friends. Not surprisingly, researchers have found that adolescents’ romantic experiences are associated with many aspects of their personal development: forming a personal identity, adjusting to changes in familial relationships, furthering harmonious relations with peers, succeeding (or not) in school, looking ahead to future careers, and developing sexuality (regardless of the extent of sexual activity). Contrary to widespread skepticism, romantic experiences also appear to be linked to qualities of romantic relationships in later life.

Four key questions frame this essay: (1) What pathway do most individuals follow in the development of their romantic experiences and behaviors? (2) What are the common features of adolescent romantic experiences? (3) What markers of individual differences in romantic experiences have been documented? (4) What is the impact of other relationships (e.g., with parents or friends) on adolescent romantic experiences?

The Developmental Course of Adolescent Romantic Experiences

Romantic experiences and relationships change substantially over the course of development, yet there is no single pattern of romantic development. In most industrialized societies, adolescents vary as to when they develop romantic interests, begin to date, or establish a romantic relationship. Some youth may have relatively few or intermittent

romantic experiences, whereas others may be seeing someone or have a romantic relationship most of the time. Typically, in early adolescence romantic relationships are relatively short-lived, but some long-term relationships may occur early on.

Features of Romantic Relationships

A fundamental challenge is identifying the relevant dimensions of variation in adolescent romantic experiences. One comprehensive approach delineates five features of romantic experiences. Romantic involvement or activity refers to whether or not a person dates, when she or he began dating, the duration of relationships, and the frequency and consistency of dating and relationships. Partner identity is concerned with the characteristics of the person with whom an adolescent has a romantic experience, such as in dating. The content of the relationship refers to what the dyad does and does not do together. Relationship quality pertains to the relative degree of positive, supportive, beneficent experiences as compared to the negative, potentially detrimental ones. Cognitive and emotional correlates include perceptions, attributions, and representations of oneself, the partner, and the relationship and emotions and moods elicited by and in romantic encounters or relationships. Attending simultaneously to several or all of these components of individual and dyadic functioning permits researchers to identify potentially significant variations in romantic experiences.

Romantic Relationships Activity

For adolescents in Western cultures, becoming involved in romantic relationships commonly occurs through a predictable series of phases first described by Australian sociologist Dexter Dunphy. Adolescents first commonly participate in cliques of four to six same-gender friends (stage one). In phase two, male and female same-gender cliques begin to interact with each other. In phase three, a mixed-gender crowd emerges and the higher status members of the earlier cliques begin to date each other and form mixed-gender cliques. In phase four, the mixed-gender peer crowd is fully developed, and several mixed-gender cliques have emerged as more individuals begin to date. As crowd members pair off, they form a new crowd of couples.

The experiences of most heterosexual adolescents generally correspond to these developmental models. Before adolescence, most interactions occur with peers of the same gender, and most friendship pairs are of the same gender. The percentage of adolescents who report having a romantic relationship increases across adolescence; popular adolescents generally date more frequently than other adolescents. For example, in a national survey, 36 percent of 13 year olds, 53 percent of 15 year olds, and 70 percent of 17 year olds report having had a “special” romantic relationship in the last 18 months. The proportions are even higher with more inclusive definitions of romantic relationships (e.g., dating, spending time with or going out with someone for a month or longer).

Less is known about the developmental course of gay, lesbian, and bisexual romantic experiences. Approximately 93 percent of sexual minority adolescent boys and 85 percent of sexual minority girls report having had some same-gender activity. Most sexual minority adolescent males were first sexually rather than emotionally attracted to a male, whereas sexual minority adolescent females were evenly divided between first having had an emotional attraction or a sexual attraction to another female. Males most commonly had had same-gender sexual experiences with a friend, whereas girls’ same-gender experiences were with a romantic partner. The average age of the first self-reported serious same-gender relationship is 18 years.

Sexual identity and the gender of the person one is attracted to can be quite fluid and can change over time, especially for women. Approximately 42 percent of girls and 79 percent of boys have reported some sexual activity with a member of the other gender, and the majority of sexual minority youth report dating members of the other gender. Thus, estimates of the prevalence of homosexuality can range from 1 to 21 percent depending upon the definition. Such variability underscores the idea that no simple dichotomy exists between heterosexuality and homosexuality.

Relationship Content, Quality, and Cognitions

The meaning of romantic relationships changes from early to late adolescence. For early adolescents having a boyfriend or girlfriend confers social

status and facilitates fitting in. Middle adolescents most commonly cite companionship as an advantage. Late adolescents and young adults more often emphasize the prospect for a special connection with the partner, compatibility, closeness, and mutual caring and support. Reports about falling in love experiences change developmentally; older adolescents and emerging adults tend to report having first fallen in love at a later age than younger adolescents, implying a redefining of prior experiences.

Other-gender peers are the most common source of positive emotions for heterosexual youth. Positive emotions are especially likely to occur when socializing on weekend nights with a romantic partner or several other-gender peers. Over the course of adolescence, the amount of time spent with other-gender peers and romantic partners in particular increases.

As romantic experiences become more common, physical and relational aggression by romantic partners also increases. Sexual harassment of both same-gender and other-gender peers increases over early adolescence as well, and these higher levels persist in middle adolescence. Sexual victimization is also relatively common throughout much of adolescence, with estimates for girls ranging from 14 percent to 43 percent.

Individual Differences in Romantic Experiences

Partner Characteristics

Like adults, adolescents report that they would like partners who are intelligent, interpersonally skillful, and physically appealing. Girls tend to have slightly older partners, whereas boys tend to have similar aged partners. Dating partners are usually similar in race, ethnicity, and other demographic characteristics, as well as in attractiveness, adjustment, and peer network characteristics. Aside from these findings, little is known about the impact of the partner on adolescent relationships and on their development significance.

Impact of Current and Past Relationships

Romantic relationships do not occur in isolation. Individual differences in romantic relationship experiences typically are embedded in each

partner's current close relationships and history of relationships.

Relationships With Parents

Parent-adolescent relationships contribute to behavioral, cognitive, and emotional patterns that have been linked to later behavior with romantic partners. Secure working models of parents are linked to subsequent capacity for romantic intimacy, whereas avoidant styles are linked to less positive romantic relationships in early adulthood. Nurturing, involved parenting in adolescence is predictive of warmth, support, and low hostility toward romantic partners in early adulthood. Similarly, the degree of flexible control, cohesion, and respect for privacy experienced in families is related positively to intimacy in late adolescent romantic relationships, with especially strong links emerging for women. Parent-adolescent conflict resolution is also associated with later conflict resolution with romantic partners.

In contrast, unskilled parenting and aversive family communications are associated with later aggression toward romantic partners. Similarly, the degree of negative emotionality in parent-adolescent dyads is correlated with negative emotionality and poor quality interactions with romantic partners in early adulthood. In fact, parenting style in adolescence contributed more substantially to the quality of early adult romantic relationships than did either sibling relationships or the models provided by parents' own marriage. Family stress and family separation are also risk factors for early romantic involvement, which in turn is associated with poor adjustment. The quality of these apparently compensatory early involvements, however, is typically poorer than that of romantic relationships for youth with more beneficent family histories.

A growing number of studies now implicate familial experiences in infancy and childhood in the romantic experiences in adolescence and adulthood. The qualities of early parent-child relationships are significantly associated with the stability and quality of adolescent and young adult romantic relationships. Closeness to parents in childhood is even a forerunner of long-term effects on relationship satisfaction in adulthood and marital stability. Longitudinal studies are now examining

both the nature of these associations across time and the processes of continuity and change that account for them.

Peer Affiliations and Friendships

Relationships with peers are also correlated with the characteristics of the romantic relationships formed in adolescence. Having a large number of other-gender friends and being liked by many of one's peers in adolescence is correlated with current and future dating patterns. General social competence with peers is associated with romantic relationship activity in early and middle adolescence and romantic relationship quality in early adulthood.

Friendships are especially implicated in the development of romantic relationships, perhaps because of the resemblance between the two types of close relationships. Friendships and romantic relationships are both voluntary, and relationships with friends function both as prototypes of interactions compatible with romantic relationships and as testing grounds for experiencing and managing emotions in the context of voluntary close relationships. Friends also serve as models and sources of social support for initiating and pursuing romantic relationships and also for weathering periods of difficulty in them, thus potentially contributing to variations in the qualities of later romantic relationships. As an example, adolescent males' hostile talk about women with friends is predictive of later aggression toward female partners.

Relatively little is known about the similarities and differences in the characteristics of friendships and heterosexual romantic relationships. In early and middle adolescence, same-gender friendships are perceived to be more supportive and intimate than heterosexual romantic partners. Perceptions of the frequency of conflict are similar, although observed rates of conflict in interactions are greater in heterosexual romantic relationships. Observed affective responsiveness and dyadic positivity are also less in romantic relationships.

Relatively little is known about the links between sexual minorities' peer relationships and romantic relationships. Those who have had more romantic relationships worry more about losing friends, although the size of the network is not predictive of the number of romantic relationships.

Social Networks

Contrary to common stereotypes of cross-purposes between parents and peers, the peer and family domains are often similar in nature, and family and peer influences often act in concert with one another. For example, a stable, harmonious family life reduces the risk of affiliation with deviant peers and both reduce the risk of choosing deviant romantic partners. Family and peer influences also may moderate each other. Parental support is associated with a reduction in criminality for those without a romantic partner, but the support of a partner is the more important factor for those with a romantic partner.

Compared to childhood relationships, the diminished distance and greater intimacy in adolescents' peer relationships may both satisfy affiliative needs and contribute to socialization for relations among equals. Intimacy with parents provides nurturance and support but may be less important than friendships for socialization to roles and expectations in late adolescence and early adulthood. Little is known about the joint contributions of relationships or the impact of the combination of parent, peer, and romantic relationships on adolescent development and adjustment.

Person Characteristics

Surprisingly, few studies have focused on the role of individual characteristics in adolescent romantic experiences. The few available findings imply that, as with adults, the nature and quality of romantic experiences are correlated with partners' self-esteem, self-confidence, and physical attractiveness. Social competence is related positively to dating and romantic experience, whereas alcohol and drug use, poor academic performance, externalizing and internalizing symptoms, poor emotional health and low job competence are associated with negative experiences. Causality is unclear, however, because these cross-sectional correlations plausibly could reflect either the effects of romantic experience on adjustment or the converse. For example, dating or romantic experience in late childhood and early adolescence is predictive of subsequent misconduct and poor academic performance, which in turn are associated with a risk of being involved in romantic relationships with negative qualities. Similarly, romantic activity

is linked to depression, especially for adolescents engaging in casual sex or with a history of unresponsive relationships; these latter conditions may also place a young person at risk for negative romantic experiences.

The multifaceted nature of romantic experiences discussed earlier implies that spurious correlates are likely. For example, romantic breakups are one of the strongest predictors of depression, suicide attempts, and suicide completions; thus, experiencing a breakup, rather than having been in a romantic relationship, may account for the correlation between romantic experience and depression. In one of the few studies to examine multiple dimensions simultaneously, psychosocial adjustment was related distinctively to romantic experience, to overinvolvement (an indicator of activity), and to the quality of romantic relationships.

Future Directions

Research on adolescent romantic relationships potentially broadens understanding of the significance of close relationships in the development of individual well-being and social competence. Many questions remain unanswered. For instance, although adolescents' reports of the quality of their relationships with different romantic partners are moderately consistent, it is unclear how much carryover occurs from one adolescent romantic relationship to the next or how much having a new partner may lead to a different experience. Similarly, despite fragmentary evidence that romantic experiences are strongly influenced by cultural and community factors, more extensive and systematic research is needed on the nature of contextual influences and the corresponding effects on adolescents and their subsequent relationships. Attention to the varied dimensions of romantic experience will provide a more complete picture of these experiences in the panoply of personal and social influences on development from childhood to adulthood.

ADOPTION

The definition of the term *adoption* appears straightforward: the legal transfer of parental rights and responsibilities from those who biologically created a child to other adults who rear the child. But the legal definition does not capture the complex human relationships that are formed and influenced by adoption when two families—who

often do not know one another—are forever joined through the child. Further, adoption is not an event, but a process. Throughout life, all parties—the original family, the adoptive parents, and the person who is adopted—must accommodate the meaning of adoption into their identities and their relationships. Further, adoption resonates beyond these parties—for example, to the partner or spouse of the adopted person, to the grandparents both original and adoptive, to the children born to those adopted. As adoption pioneer Kenneth Watson has noted, adoption is a profound experience that encompasses universal human themes of love, loss, abandonment, sexuality, parenthood, kinship, and identity. Adoption raises questions about nature and nurture, about biological connection and belonging, and about the meaning of family. Thus adoption has not only legal but also social and psychological dimensions. This entry considers such dimensions, briefly reviewing theory, research, and the history of adoption.

Adoption: Theory and Empirical Examination

Although much has been proposed about the impact of adoption on identity and relationships, both theoretical explication and empirical testing is limited. What is known is that well-designed studies consistently find that families formed through adoption are successful—with high levels of satisfaction reported by adopted persons and by those who adopt them. For example, several studies have found that adopted children (especially those adopted following maltreatment or otherwise compromised early lives) have more behavior problems, especially in adolescence, but others have not found large differences. The common theme in studies of families formed through adoption is that children fare well and that families are cohesive. Researchers know much less about the long-term impact on birth or first families.

Despite positive outcomes, theory predicts that adopted persons face additional challenges to positive identity formation. In psychoanalytic theory, relationships in adoption are seen as holding risk for psychopathology. Freud posited the concept of family romance—the fantasy-based disavowal of one's parents as real parents allowing for safe expression of anger or of ambivalence

toward the all-powerful parents. The romance enables children to separate and develop the psychological independence necessary for healthy adulthood. But this fantasy is problematic for adopted youth who must come to an understanding of why they have been separated from their original families—a separation that may be interpreted as rejection.

Developmental psychology, especially Erik Erikson's model of human development, holds that identity development and consolidation is a normative developmental step. Identity confusion may result from the lack of information about important aspects of self and history. Such informational lack is common in many adoptions.

Loss and grief theory (Bowlby) informs adoption theory as well. The breach of attachment and the lack of resolution of loss are held to complicate relationships. The loss for the birthmother has been particularly complex due to the stigma and secrecy surrounding adoption historically. For those adopting, the loss of the imagined or desired child that may occur when parents adopt rather than procreate is another complication, particularly when due to infertility. For adopted persons, particularly those with no connection to their original families, loss may be retrospective—realized and understood at relatively late developmental stages. Loss theory holds all are constrained by the ambiguity of loss and the dearth of social mechanisms that acknowledge and support grieving this type of loss. Unresolved loss can interfere with positive adoptive adjustment as well as impair the birthmother's capacity for psychologically healthy relationships.

The social reality that adoption differs from forming a family through birth also informs adoption theory. David Kirk's theory of adoption acceptance of difference versus rejection of difference predicts that more positive adjustment in the adoptive family results from both open and comfortable communication about adoption, and parental acceptance that forming a family through adoption is different. Denial of difference, exacerbated by the historic practice of matching (i.e., placing children with adoptive parents who resemble them physically, temperamentally, and intellectually) and by secrecy, inhibits family examination of important differences. David Brodzinsky has expanded the concept to include insistence on

difference, wherein difficulties in family relationships or child behaviors or abilities are seen as due to the otherness of the child. In his model there is a curvilinear relationship between levels of acknowledgment of difference with the most positive outcomes resulting from acceptance and less positive outcomes with both denial of and insistence on difference. Empirical examination of the Kirk and Brodzinsky view has been conflicting, with some studies finding that families where adoption is rarely discussed (identified as denial families) functioning well. The key element appears to be the overall comfort level of the family.

Another thread of adoption theory relates to search and reunion. In much of the 20th century, the need to search for one's original family or even for information about them was seen as pathological at worst or indicative of a bad adoption experience at best. More recently, the adoption movement and an emergent understanding of loss has led to a beginning shift in view—that retrieving information is a logical and perhaps necessary step to wholeness, and the relationships with birth family members may also contribute to psychological health.

It is important to note that theories used to examine adoption generally flow from the assumption that a family formed by birth is not only normative but preferred. Although most children are reared by at least one of their original parents, it is important to note there are a range of functional, nurturing family types in the contemporary United States. Theory related to adoption needs to be appraised for its assumptions of the superiority of the natalist family form, as well as in the context of modern family life and adoption practice.

Adoption History and Its Implications for Relationships

Although informal adoption (caring for children who are orphaned or otherwise without parental care) is as old as humankind, formal adoption is a relatively new invention. Legal regulation of adoption began in the United States in the 19th century. However, it was not until 1917 that the first law required investigation of child and family circumstances and the suitability of prospective adoptive parents and that adoption records be

confidential. By the 1950s, almost all states required investigation of adoptive parents' fitness, a period of supervision after placement, and the permanent sealing of records. In the post-World War II period, as more children became available for adoption and more couples had the means to adopt, matching children to families became common. Placing infants with parents who resembled them physically or even were thought to have similar intellect or capacity was the goal. Such practice further masked adoption. Simultaneously, mothers placing children were encouraged to hide their pregnancy, often disappearing to maternity homes while family members invented stories for their absence. The permanent sealing of adoption records and the reissuing of birth certificates with the adoptive parents' names further reinforced the social beliefs that illegitimacy was a stain to be concealed. That adopted children did not need information about their origins, that adoptive parents would fully replace a child's original family, and that a birthmother should move on with her life without further thoughts of the lost child were widely held beliefs of this period.

The numbers of adoptions of infants in the United States peaked in 1970 when over 170,000 adoptions were finalized. Shifting social mores in the 1960s and '70s coupled with greater access to birth control and the legalization of abortion led to dramatic declines in infants placed for adoption. Although the numbers of domestic infants declined, adoption of children from other countries and across race and ethnicity increased.

Both after World War II and particularly after the Korean conflict, the plight of children who were often the children of servicemen or who were otherwise vulnerable became public, and these children began to be adopted by American couples. In the 1970s, growing social awareness of the needs of older children and of children of color languishing in the child welfare system led to a movement to find adoptive homes for these previously labeled unadoptable children. Today adoption of infants is increasingly rare, although intercountry adoption is rising. Adoption from foster care is now the largest category of adoptive children. Statistics on infant adoption are not compiled in a central database. The Donaldson Adoption Institute estimates that about 135,000 nonstepparent adoptions occur annually. About

10,000 are adoptions of infants surrendered by birthparents, 26 percent are international adoptions, and the majority, 59 percent, are of children adopted from the foster care system.

Secrecy and Adoption

Beginning in the 1970s, challenges to secrecy in adoption and to permanent separation began and gained momentum. Fueled in part by organizations of adopted persons and of mothers whose children had been placed for adoption, the movement first revealed the pain suffered by many whose original connections were severed and later pushed for reform to make adoption more open, more informed, and less necessary. A range of works describing the profound loss and psychological distress felt by adopted persons and the shame and struggle of surrendering mothers accompanied the movement. For example, Betty Jean Lifton's *Lost and Found* presented adoption as a complex and life-altering process for the adopted. *The Other Mother* brought voice to the pain felt by many birthmothers and the need to protect the rights of vulnerable pregnant women and for openness after adoption. At the same time others, particularly some birthmothers, saw secrecy as protecting desired privacy. Despite some recent legislative changes in a small number of states, birth records remain sealed for most adopted persons, and original parents do not have a right to information about their children's adoption.

Adoption Types

Adoption From Foster Care

Children adopted from the child welfare system differ from the stereotypical adopted child (i.e., an infant whose parents choose to relinquish the child because they are unable to care for the child). Data from the U.S. Children's Bureau indicates they are older (mean age of 6.7, median 5.6) and have experienced maltreatment in their original homes and sometimes in the child welfare system as well. Most of these children are adopted by those who know them—either foster families who have been serving as substitute parents (the case for 60 percent) or by kin (25 percent). A small percent of children (15 percent) are adopted by matched

families, those who were not part of the foster system, but became so for express purpose of adopting. Further, most children adopted from foster care have experienced maltreatment.

Because it is the first goal of the child welfare system to reunite children with their parents, most children in foster care have regular visits with their parents, siblings, and sometimes other relatives. Thus, children adopted from foster care are likely to have memory of and a relationship with their first families.

A growing percent of children adopted from foster care are adopted by parents of a different race or ethnicity. Thus, such adoptions are conspicuous—it is clear to the outside world that this family was created by adoption. Those adopted across race and ethnicity have additional challenges to identity development beyond those of other adopted persons.

Children adopted from foster care have memory, know history or at least part of it, and have to fold maltreatment or parental incapacity into self-understanding. Their adopting parents may know original family and must manage the reality of harm by first family with the need to help the child overcome these difficulties and develop a positive sense of self.

International Adoption

By definition, adoption of children from other countries is transcultural adoption. The child joins a family who typically has language, customs, and experiences different from his or her own. In many cases, these are also transracial adoptions. Whether transcultural or transracial, international adoptions are often conspicuous. That is, the family is visibly identified as a family formed through adoption in the community, in schools, and in social situations.

Those adopted across national boundaries have additional challenges. Initially the loss of culture, language, and all that is familiar, as well as separation from attachment figures may lead to a profound experience of loss. As the child ages, identity development must include interweaving being adopted, having origins in another country, and often being of a different race or culture from one's parents. Finally, search and possible reunion is made more complex by differences in culture and

language, geographic distance, and continuing policies in some sending countries of retrieving and keeping little information or failing to make information about original family available.

Domestic Infant Adoption

The significant majority of infant adoptions are to two-parent families who face obstacles to conception. The significant majority of adoptions of infants in contemporary America are open to some degree. Current American adoption practice allows for and often promotes some type of ongoing communication between the parents who created the child and the adopting family in most cases. This openness may be direct and continuing (e.g., Sarah's first mommy is invited to and attends Sarah's birthday party, visits often, and is a part of family life, and Sarah knows her mother's parents, her cousins, etc.). It may, however, be limited to periodic letters and pictures exchanged through the agency or broker arranging the adoption. Whatever the level of openness, in modern infant adoption most birthmothers choose the family they wish to raise their child and most meet the prospective parents and many continue some type of relationship, whether regular or episodic. Further, in contemporary American adoption, most birthmothers are not young teens (who comprise only about 25 percent of those surrendering). Birthfathers continue to be largely absent from the process.

Stepparent Adoption and Family Adoption

A final adoption type is when a child is adopted by the spouse or partner of a biological parent with whom they live. Most typical is the adoption of a child by stepfathers whose social and psychological parenthood is codified through legal adoption. Like all adoptions, stepparent adoption involves the restructuring of family definitions and the loss of formal relationship with a parent.

Conclusion

The increasing social acceptance of adoption and public discussion rather than secrecy about this method of family formation likely will reduce the complexity which may face all members of the adoption triad. In addition, emergent understanding

of the legitimacy and value of an array of family types, coupled with on-going research assessing the impact of adoption and theory that does not assume the superiority of families formed through birth can lead to a more complex understanding of adoption.

ADULT ATTACHMENT, INDIVIDUAL DIFFERENCES

John Bowlby, the originator of Attachment Theory, proposed that humans have a biologically

based inclination to form strong emotional bonds with others, called attachment bonds. From infancy through adulthood, these close attachment relationships provide a sense of emotional security, and being without or losing these relationships leaves people distressed and lonely. Adults, therefore, are highly motivated to form and maintain close relationships with romantic partners, close friends, and family members. However, adults differ in their capacity to maintain satisfying relationships and in their characteristic strategies for regulating feelings of security within their relationships. These differences stem, at least in part, from their experiences in childhood attachment relationships, which become internalized in expectations about close relationships and characteristic emotional and behavioral patterns within close relationships. This entry reviews research about individual differences in adult attachment and the implications of these differences for personal and social adjustment.

How Do Researchers Think About Individual Differences in Adult Attachment?

Infants and young children differ in the quality of their attachments with their adult caregivers. Cindy Hazan and Phillip Shaver proposed that distinct patterns of attachment may also characterize how adults function in their adult love relationships. They conceptualized romantic love as an attachment process and developed a measure to identify adult analogues of the original three infant attachment patterns: secure, avoidant, and ambivalent. Adults were asked to choose which of three brief paragraphs describing each style best captured their experiences in romantic relationships. *Secure* adults were characterized by high trust and comfort with closeness and mutual dependence in love relationships. *Avoidant* adults were characterized by discomfort with closeness and difficulty in trusting and depending on love partners. *Anxious-ambivalent* (also referred to as *preoccupied*) adults were characterized by a strong desire for closeness coupled with anxiety about rejection and abandonment. This simple classification was related to people's beliefs, expectations, and experiences in romantic relationships, as well as their childhood experiences with parents.

Hazan and Shaver's initial application of Attachment Theory to adult relationships proved remarkably fruitful, laying the foundation for hundreds of research studies. As well as replicating and extending the original research, researchers proposed various revisions and refinements to Hazan and Shaver's original conceptualization of adult attachment styles. Notably, Kim Bartholomew proposed that two distinct forms of avoidance could be identified in adulthood—a fearful style characterized by avoidance driven by fear of rejection and loss (similar to the original avoidant style) and a dismissing style characterized by defensive self-reliance and independence (similar to the dismissing pattern identified by the Adult Attachment Interview). In addition, researchers quickly realized that people do not fall neatly into one of three or four attachment categories. Rather, most people differ in the degree to which their experiences and expectations fit each attachment style. For instance, two individuals may be predominately secure, but one may have secondary avoidant tendencies and the other, secondary preoccupied tendencies, resulting in quite different presentations. Some researchers have further suggested that the very notion of distinct attachment styles or types is suspect.

It is now generally accepted that variation in adult attachment is best understood in terms of two continuous dimensions, *anxiety* and *avoidance*. Anxiety refers to the tendency to experience anxiety over rejection, separation, and abandonment; individuals high in anxiety are hypersensitive to anxiety-related threats, whereas those low in anxiety have trust in their attachment figures and are less prone to perceive threats. Avoidance refers to the behavioral strategy used to deal with attachment-related anxiety; individuals high in avoidance maintain distance and seek to deal with distress on their own, whereas those low in avoidance approach others for support to help regulate anxiety. See Figure 1 for a diagram of how four distinct attachment styles—secure, preoccupied (anxious-ambivalent), fearful avoidant, and dismissing avoidant—can be conceptualized as regions in the space defined by the anxiety and avoidance dimensions. This model of adult attachment emphasizes the dynamic operation of the attachment system. Thus, secure attachment is defined in terms of a relatively low threshold for activation of attachment anxiety and a tendency to approach

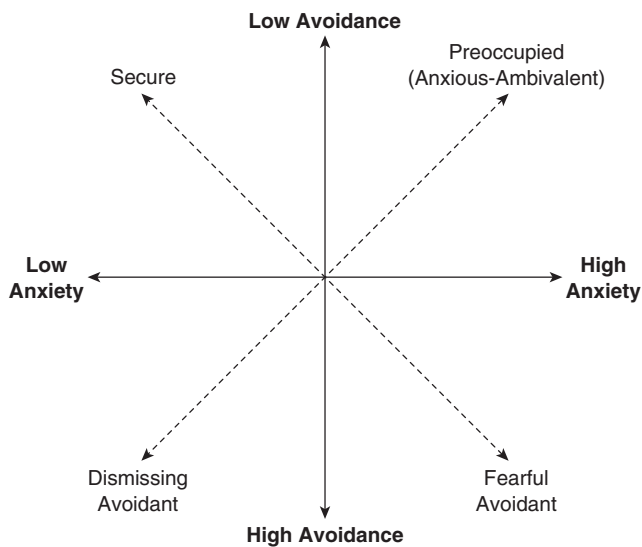

Figure 1 Diagram of the Two-Dimensional Space Defined by Attachment Anxiety and Avoidance

attachment figures for support when anxiety is triggered.

Assessment of Adult Attachment

As thinking about adult attachment developed, researchers developed a number of new approaches of assessing adult attachment style. These methods of assessment vary widely in format (e.g., self-report versus interview-based assessment), specificity (e.g., focus on adult relationship in general or a specific relationship), and in the conceptualization of attachment (e.g., distinct styles or dimensions). However, the measures share the goal of moving beyond a simple self-categorization of attachment styles to provide a more fine grained analysis of variability in adult attachment. Most of these measures consist of multiple items summed together to provide a rating of each attachment style or of the dimensions underlying the styles. Currently, the most widely used measure of adult attachment is the Experiences in Close Relationships (ECR) Scale developed by Kelly Brennan and her colleagues. This multi-item measure of the attachment dimensions of anxiety and avoidance assesses where individuals fall within the two-dimensional space pictured in Figure 1. The ECR

can be worded to apply to various classes of relationships—close relationships in general, romantic relationships in general, or a particular relationship—making it useful for a wide range of research applications.

Implications of Individual Differences in Adult Attachment

Coping and Individual Adjustment

The self-confidence and trust in close others associated with secure attachment promotes effective coping. Secure individuals are able to realistically appraise threatening situations and to respond flexibly, including approaching close others for support when needed. In contrast, individuals with high attachment anxiety tend to be hypersensitive to threats and to focus and ruminate on those threats, a behavior that interferes with adaptive coping. The avoidance dimension of adult attachment predicts how individuals respond when they experience stress or anxiety. Those low on avoidance are comfortable turning to others for support, whereas those high on avoidance emphasize self-reliance and rely on defensive denial or suppression of distress. Although this strategy of distancing appears to work quite effectively for the minor stresses of daily life, it is less likely to be effective for coping with major stresses, such as directly experiencing (and surviving) the September 11, 2001, attacks on the World Trade Center. As would be expected given the links between attachment and coping, adult attachment is related to various indices of individual health and well-being. Insecure attachment, and especially high attachment anxiety, is associated with experiences of depression, anxiety, conduct problems, substance abuse, physical health, and even posttraumatic symptoms among those exposed to traumatic events.

Perceptions of the Self and Others

Consistent with the proposition that secure attachment derives from a history of feeling valued and accepted within close relationships, security is strongly associated with high self-esteem and with realistic and coherent self-perceptions.

Also consistent with a history of supportive relationships, secure attachment is associated with positive perceptions of interaction partners. Secure individuals (those low in anxiety and avoidance), relative to less secure individuals, tend to trust in others' supportiveness and good intentions and to interpret ambiguous or negative behaviors by others in more understanding and benign ways. In contrast, anxious attachment is associated with a more vulnerable sense of self-worth, and both anxiety and avoidance are related to negative perceptions and expectations of others. These views of interaction partners also extend to views of others in general, including strangers and members of outgroups. For instance, Mario Mikulincer and Phillip Shaver have found that Israeli Jewish students high in attachment security show less hostile attitudes toward people who do not belong to their own group, such as homosexuals, Russian immigrants, and Israeli Arabs.

General Interpersonal Functioning

Adult attachment styles are reflected in people's goals and habitual ways of interacting in their social relationships. Whereas attachment security is characterized by the capacity to maintain a comfortable balance of closeness and independence in relationships, both high anxiety and high avoidance compromise smooth interpersonal functioning, especially within close relationships. Individuals high on anxiety strongly desire closeness and acceptance in their close relationships, but their hypersensitivity to rejection and abandonment interfere with meeting this goal. Especially when they are also low on attachment avoidance (falling in the preoccupied space in Figure 1), anxious individuals tend to be intrusive and demanding in their relationships. Unfortunately, these excessive demands for intimacy and reassurance tend to alienate and push away relationship partners, the opposite effect to what is desired. In contrast, those high in avoidance seek to maintain a comfortable level of distance in their relationships, presumably as a way to defend against the dangers of rejection and loss. This stance results in difficulties in getting close to and depending on others, including low expressiveness and low disclosure within relationships.

Functioning in Romantic Relationships

Adult attachment is associated with interpersonal functioning in a broad range of domains, including daily interactions with friends and acquaintances. However, following from Hazan and Shaver's initial focus on love relationships, the majority of research attention has been given to the implications of attachment for experiences in intimate couple relationships. A large body of research documents that secure attachment is associated with greater satisfaction and better adjustment in both dating and marital relationships. These associations do not merely reflect positive perceptions associated with security. The partners of secure individuals also report greater satisfaction, and a few studies indicate that security predicts relationship adjustment and breakups over periods of a few years.

Considerable research has explored the processes through which adult attachment styles may impact relationship functioning. Attachment styles have been found to be associated with almost every aspect of romantic relationships: initiation, maintenance, and ending of relationships; communication in relationships; the quality of caregiving partners provide for each other; and even the quality of sexual relations. In fact, Hazan and Shaver argue that attachment can serve as a framework for understanding and integrating the large body of theory and research on close relationships. Particular research attention has been given to attributions within relationships and communication and conflict. Consistent with findings that security is associated with positive perceptions of others, secure people tend to hold more positive views of their romantic partners and to interpret their partners' actions, even ambiguous or negative actions, in a more positive and understanding light. These attributions then impact on how people feel and act in their intimate relationships. For instance, secure people are more inclined to forgive a romantic partner for having done something hurtful, whereas insecure people tend to respond to transgressions by partners with greater hostility and less forgiveness.

Communication is central to many aspects of couple relationships: expressing affection and appreciation, expressing the need for support and providing partner support, and dealing with the

inevitable conflicts of interest and hurt feelings that arise in close relationships. Across domains, secure attachment provides a foundation for comfortable and open communication. High avoidance, in contrast, is associated with a more distant communication style, including difficulty in expressing affection and providing sensitive support to partners. Although anxiety is associated with high engagement in couple interactions, the high anxiety and negative attributions of the highly anxious interfere with constructive and sensitive communication.

The communication patterns linked with attachment styles are highlighted in conflict situations. Secure partners are able to maintain a more positive, constructive, and accommodating approach in conflict discussions, helping to keep conflicts from escalating and remaining unresolved. Both forms of insecurity (high anxiety and high avoidance) are associated with less effective management of couple conflict, but most striking is the link between anxious attachment and destructive approaches to dealing with conflict. Highly anxious people, fuelled by insecurities and negative partner attributions, are especially likely to strike out aggressively in conflict discussion, thereby escalating conflict. Moreover, there is some initial research evidence that couples comprised of partners with incompatible insecure styles—one partner high in anxiety and the other high in avoidance—may be at particular risk for developing dysfunctional and even abusive communication patterns.

Do Adults Really Have a General Attachment Style?

Hazan and Shaver originally conceptualized adult attachment in terms of a general style across romantic relationships. Some subsequent researchers broadened this focus to include all adult close relationships, under the assumption that nonromantic relationships also function as attachment relationships. Other researchers have narrowed the focus to look at the quality of attachment within a specific adult relationship. Research suggests that at best there are moderate associations between people's reported security across their adult close relationships (e.g., across

their relationships with a romantic partner, best friend, and sibling). Based on the erroneous assumption that a style requires consistency across all close relationships, this finding has sometimes been interpreted as evidence that there is no general attachment style. However, findings that general attachment styles are predictive of functioning in a broad array of domains and are moderately consistent over time indicate the validity of the concept of a general style because an attachment style simply summarizes an individual's emotional and behavioral tendencies in close relationships.

Attachment security differs to some extent across relationships because experiences in any given relationship are a function of what people bring to the relationship, what their partner brings, and how the two interact at a particular point in the relationship. For instance, if a woman high in anxiety is paired with a partner who is distant and unsupportive, her partner's behavior will reinforce her feelings of not being valued and supported, enhancing her anxiety in this relationship. (At the same time, her attempts to seek closeness may reinforce her partner's preference for distance!) But if the same woman is paired with a consistently supportive partner, over time she may come to trust that her partner cares for her and to feel less anxious in that relationship. Similarly, when attachment is considered at the level of a specific relationship, the relationship-specific style reflects a general tendency in that relationship. Attachment security shifts within relationships across context and over time. Even the most secure individual will become less secure within a relationship that is on the way to dissolution. Some new research by Mario Mikulincer and Shaver further indicates that attachment security can be temporarily enhanced by simple priming procedures in a laboratory, highlighting the dynamic nature of adult attachment processes.

In summary, individual differences in adult attachment can be thought about in a number of ways, from a general style to tendencies in a given relationship to attachment strategies in a specific context. Each of these approaches can be useful. For instance, if researchers seek to understand why some people are chronically lonely or are unable to maintain satisfying close relationships, it may be

most helpful to think about how their general attachment style is impacting on their interpersonal adjustment. But if researchers are interested in understanding problematic communication patterns within couples' relationships, it may be most useful to consider how both partners' attachment styles interact within that relationship. Recent research is further extending the notion of attachment styles to understanding the therapeutic process, leader–follower relationships, and even group processes. It is remarkable that the basic dynamics of adult attachment, captured in a quite simple model of responsiveness to threat (anxiety) and tendency to avoid or approach close others for support (avoidance), can be applied so widely and so productively.

ADULT ATTACHMENT INTERVIEW

The Adult Attachment Interview (AAI) is an interview and coding system developed by Mary Main and colleagues that yields a classification of an adult's current state of mind with respect to attachment. The following entry presents a description of the AAI, its coding, and basic research findings.

John Bowlby hypothesized that individuals develop an “internal working model” or cognitive representation of the functioning and significance of close relationships that guides behaviors, thoughts, and feelings in those relationships. The AAI was developed to assess the security of an adult's general or overarching working model of attachment, not to assess the security or quality of attachment to any particular person. The use of a narrative to assess adult attachment is based on the idea that attachment-related cognitive processes vary as attachment behavioral patterns do in infants and children, and these processes are reflected in the language of older individuals. The AAI is not published; it requires skillful interviewing and intensively trained coders.

The AAI has 18 autobiographical questions, starting with family background, an overview of the relationship with parents or parental figures in childhood and a request for five adjectives describing the relationship with each parent. The individual is asked for a specific experience that illustrates each adjective. The interview asks about ordinary childhood experiences in which the attachment system is activated (e.g., upset, injury, illness), as well as experiences of loss and abuse. The individual is asked how the childhood attachment experiences have influenced their adult personalities and about hopes for their children.

The AAI is audiotaped and transcribed verbatim for scoring. Scoring is based on (a) the coder's assessment of attachment experiences with parents, (b) the language used in the interview, and

(c) the ability to give an integrated, believable account of experiences.

Experience scales are used to rate the degree to which each parent demonstrated loving behavior; demanded premature independence in the child (rejection); engaged in involving, role-reversing behavior; pressed the child to achieve; and/or neglected the child. The experiences are inferred by the coder and are not necessarily accurate autobiographical information.

Several scales assess states of mind, with the coherence of transcript score being the strongest correlate of overall security. High coherence means that the narrative demonstrates consistency, clarity, and cooperative collaboration with the interview process. Scales associated with insecurity include idealization, insistence on lack of recall, active anger, derogation, fear of loss, and passivity of speech. Two scales identify unresolved or disorganized states of mind associated with experiences of loss and/or abuse.

AAI Classifications

Using the rating scales, the coder assigns a major classification of secure-autonomous, insecure-dismissing, insecure-preoccupied, or rarely, “cannot classify.” The determination of an unresolved classification is also made.

Individuals classified as secure-autonomous value attachment relationships and view attachment-related experiences as influential in development. They are coherent in that broad descriptions of parental behavior (e.g., loving, caring) are supported by specific memories of loving, caring behaviors. They are open and cooperative regardless of how difficult the material is to discuss. A balanced view of experience is often apparent in the empathic discussion of imperfections of the self and parents, warmth, humor, and/or other attempts to understand behavior. These individuals are able to identify both positive and negative effects of experience on their adult personalities and do not identify with or support negative parental behavior.

Insecure Classifications

These classifications represent normal variations in attachment patterns in the general population.

However, research suggests that AAI insecurity is a risk factor for problems in close relationships, impaired adaptation to stress, and for some forms of psychopathology.

Insecure classifications are associated with incoherent accounts such that broad assessments of relationships with parents are not matched by specific descriptions of parental behavior. Adults classified as insecure-dismissing seem uncomfortable with the interview, deny the impact of attachment relationships on personality development, and have difficulty recalling specific events. They often idealize their experiences, stating they had normal or typically loving parents yet giving specific descriptions of parental rejection. Other features include an emphasis on strength and independence; little to no expression of need, sadness, or distress; sarcasm; and/or sometimes an emphasis on material aspects of the relationship.

Adults classified as insecure-preoccupied show angry preoccupation regarding parents, confusion or oscillation about past experiences, or appear overwhelmed by frightening experiences. They give reports of nonloving, involving, even role-reversing parenting in which they needed to be alert to parental needs. The descriptions are typically marked by active anger or passivity and jargon and are not balanced—that is, either overtly or implicitly, they blame themselves or others for various experiences.

In a few instances, most commonly in high-risk samples, there is an atypical combination of insecure scale scores. Such interviews are markedly incoherent. In such cases, a classification of insecure—cannot classify is given with the best fitting major classification.

Individuals may be classified as unresolved in addition to one of the major classifications. Unresolved adults report attachment-related traumas of loss and/or abuse and show confusion and disorganization in the discussion of those topics.

Studies With the AAI

Over half of adults in samples from the general population, including samples from the United States, Europe, and Israel, are classified as secure, and about 20 percent receive an unresolved classification in addition to a major classification. In

contrast, about 10 percent of adults in clinical and at-risk samples are classified secure. Men and women are equally likely to be classified as secure.

AAI classifications rarely change over time; studies have shown that 80 to 90 percent of individuals keep the same classification for up to 13 years. The secure classification is the most stable such that an individual classified as secure is very unlikely to be reclassified as insecure at a later time.

AAI security is not associated with memory, the desire to give socially acceptable responses, or a person's general way of speaking. There are significant associations between coherence and day-to-day functioning, suggesting that attachment representations serve a function regarding adaptation and coping with stress. Adults classified as secure are more likely to have children classified as secure and to have been secure children, although important life experiences that change caregiving (e.g., serious parental illness, serious illness in the child, death of a caregiver) certainly can lead to change in attachment status between infancy and adulthood. Adults classified as secure are observed to have more effective, sensitive, and responsive attachment and problem-solving behaviors with their adult romantic partners and children.

The AAI addresses each of the legs of the attachment control system: behavior, cognition, and emotional appraisal and regulation. It presents rich data about recollections of attachment experiences and behaviors and is a well-validated measure of adult attachment with respect to the core aspects of Attachment Theory.

ADULTHOOD, SIBLING RELATIONSHIPS IN

This entry describes relationships among adult brothers and sisters. It explains the bases for those relationships in terms of the many ways siblings can be connected to one another and why these sibling relationships are studied. Then the entry identifies the important qualities of the relationship and some of the factors that influence these qualities. Because there are good review articles available, the emphasis here is on new ways of thinking about siblings and current research results concerning influences on what adult siblings feel about and do for one another.

Structural Bases for Sibling Relationships

The study of sibling relationships has taken a back seat to other relationships within families, particularly those between spouses and those between parents and children. However, siblings are a pervasive influence in the life of most adults. Many adults have grown up with one or more siblings. Almost 90 percent of adults in the United States have at least one sibling, according to the 1994 General Social Survey. Sibling relationships result from birth, adoption, marriage, or cohabitation of parents; the terminology varies accordingly. Full siblings have the same mother and father by birth or adoption. Half-siblings have only one parent in common, whereas stepsiblings have no parents in common but are considered siblings because their

parents are married to each other. Quasi-siblings have parents who are cohabiting. A sibling may also be informally adopted as is the case of fictive siblings among people who consider themselves to be like brothers or sisters with one another. Finally, additional siblings may be obtained through marriage of one's brother or one's sister as is the case with a brother-in-law and sister-in-law.

Various aspects of the relationship have important implications for the meaning siblings have for each other. In terms of longevity, sibling relationships can span the entire life course, but sometimes they can be temporary (e.g., if a parent's remarriage ends and ties with stepsiblings are not maintained) or relatively recent (e.g., acquiring half- or stepsiblings in adulthood). In general, active relations between full siblings continue throughout adulthood, both because the parents encourage the relationship and because many people feel attached to their siblings and want to be in contact with them.

Whether or not it is long-lived, the sibling relationship is not one of choice but rather depends on parental actions. Whereas this condition has the disadvantage of not being chosen by another (except in the case of fictive siblings) and therefore not necessarily desired, it has the great advantage of providing ready-made social partners. Regardless of how siblings are acquired, the rules about how adult siblings should feel and behave toward one another are unclear or ambiguous.

In American and European societies (as opposed to agricultural societies), whether one feels bonded to one's sibling is up to the individual. At the same time, it is expected that siblings should be involved in one another's lives; they should feel a sense of commitment toward one another. These potentially conflicting expectations may generate feelings of ambivalence. However, most adults feel close to their sibling(s) and consider relationships with their siblings as very important.

Whether siblings are expected to be altruistic to one another when it comes to giving and receiving help differs when compared to other relatives. According to the concept of kin altruism, a favor to a relative does not necessarily have to be returned, as opposed to reciprocal altruism where relationship partners expect reciprocity over time. Siblings are both kin and peers, and therefore,

although obliged to help, they may insist on reciprocity. In fact, people are more likely to exchange practical support with a sibling than with a friend (but less than with parents and adult children). As a result, most adults feel sure their siblings would be there for them if needed, which provides a sense of security and a social safety net.

Importance of Research on Adult Sibling Relationships

Focusing on sibling relationships not only reveals how siblings support one another, it also opens the door to other neglected relationships within the (extended) family. For instance, investigating sibling relationships leads to adults' broader social networks because siblings are links to other relationships, such as nephews, nieces, great nephews and nieces, uncles, aunts, great aunts and uncles, and cousins of various degrees, as well as to the network ties of these relatives. Also, attending to sibling relationships opens researchers to other neglected aspects of adult life. For instance, many adults are not legally married, and they do not have living children or living parents. Thus, when adult sibling relationships are the focus of scholarly interest, adults who inhabit a wide variety of family forms emerge, such as single-parent family, single-person households, domestic partnership with same-sex partner, domestic partnership with opposite-sex partner, traditional nuclear family, divorced family, and stepfamily.

Qualities of Adult Sibling Relationships

Sibling relationships are rated on specific emotional qualities such as closeness, conflict, separateness, indifference, and ambivalence. The emotional content of the relationship is described in terms of its intensity (strength) and its valence (positive and negative direction). The emphasis is on feelings, such as closeness (affectual solidarity), and behaviors toward siblings, such as socializing with one's brother(s) and sister(s) (associational solidarity) and giving and receiving instrumental help and assistance (functional solidarity), as well as the frequencies of those behaviors. Sometimes qualities and behaviors are grouped into types of sibling relationships, such as intimate, congenial,

loyal, apathetic, and hostile. Various influences on the relationship have been studied, such as how closely siblings live to each other (proximity) and frequency of contact with one another.

Influences on Sibling Relationships

What makes some siblings more congenial than others? What makes some siblings more caring and more likely to help and accept help from sibling(s)? Several factors influence the quality of the sibling relationship, such as the sibling constellation, the size of the family, parental influences, the type of family (e.g., stepfamily), and influences from sources outside the family.

Influences of Sibling Constellation

The sibling constellation (sibship) itself may influence the relationship between or among adult siblings. The smallest sibship, also known as a dyadic sibling relationship, contains two siblings. Constellation influences can be gender related (sister–sister, sister–brother, and brother–brother in the case of sibling pairs), related to the total number of living siblings, age spacing between the siblings, birth order (position of each brother and sister relative to the others), zygosity of the sibship (number of identical and fraternal twins), and genetic relatedness (full siblings, half siblings, and stepsiblings). The most important constellation influences follow.

Gender patterns. The influence of gender has been studied the most. Dyads with sisters (sister–sister or sister–brother) seem to be emotionally closer than those of brothers, but some researchers find that same-gender sibling pairs (brother–brother, sister–sister) are closer than cross-gender sibling pairs. One reason for this difference is that men and women tend to express intimacy differently so that men express their affection toward brothers more indirectly than do sisters toward siblings of either gender. Men's and women's sibling affection, therefore, cannot be compared by using the same yardstick. Gender influences are also seen in parent care situations. For instance, sisters tend to consult with and organize sibling participation, whereas brothers act alone, directly in response to the parent's perceived needs.

Family size. Whether siblings seek comfort from one another (or function as attachment figures) is related to zygosity. Twin pairs and nontwin pairs do so in young adulthood but twins are more likely to do so. The same factors contribute to becoming attachment figures among twins and nontwin sibling pairs, namely, having spent time together as children and having shared interests, personal lives and/or similar professional lives as adults. Further, larger families have a positive influence on siblings because those families offer many opportunities for forming positive sibling relationships since there are more siblings present. Thus, brothers and sisters in larger sibships usually have greater affection, contact, and support.

Parental influences. Negative relationships with parents affect the adult sibling relationship, sometimes in positive ways. For instance, when they have poor relationships with their parents, siblings compensate for parents' lack of support. Treating their children differently is considered poor parenting, and the children's relationships with one another tend to suffer due to jealousy, rivalry, and a sense of entitlement. In fact, early differential treatment (parental favoritism) has a negative outcome for adult children. Both young adults and middle-aged adults who are treated differently are more jealous of their siblings than are those who perceive their parents' treatment to have been equal. The quality of the adult sibling relationship diminishes with both increasing favoritism and disfavoritism.

Another source of parental influence on siblings is the death of one or both parents. The effect during adulthood is varied; it draws some siblings closer together, whereas other siblings become more distant from one another. Sometimes parental death may remove the linkage between adult brothers and sisters altogether.

Family type. Nontraditional family forms may influence sibling relationships. Adults in stepfamilies tend to feel closer to their full siblings than to their half- and stepsiblings. However, it is not yet known whether this finding is a result of preference for genetically closer kin, preference for a (full) sibling who is close in age, propinquity (whether the siblings lived in the same household while growing up), parental favoritism, or a combination of those conditions.

Nonfamily Influences

Recently, scholars have expanded their research focus to nonfamilial influences on adult sibling relationships, such as urban versus rural environments; level of educational attainment; the influence of ethnicity, education, and immigrant status on geographic proximity; and changes throughout the life course. This systematic investigation of myriad factors influencing sibling relationships has led to some promising research outcomes. For instance, a focus on rural siblings reveals that they tend to remain an active presence in the kinship networks of elderly women. Even though some siblings die, the frequency of contact with surviving siblings remains the same, suggesting that other siblings probably fill the voids left by deceased siblings.

Ethnicity, educational level, and gender influence changes over time in how often siblings interact and how far they live from each other. For instance, women and Latinos increase contact with their siblings during the life course, whereas individuals with higher levels of educational attainment and recent immigrants are more likely to increase their geographic distance from their siblings. However, African Americans and people from large families tend to stay geographically close to their siblings.

In the 1980s, sibling research was still in its infancy. Since then, scholarly interest has grown in leaps and bounds. No doubt the Baby Boomer generation (composed of those born between 1946 and 1964)—with the largest sibships of the 20th century, which shifted family landscapes, and expanded life expectancy—have helped to usher in this overdue acknowledgment of one of the most fundamental human relationships.

ADVICE, SELF-HELP, AND MEDIA ADVICE ABOUT RELATIONSHIPS

Given the value of relationships for personal happiness, the well-being of families, and the cohesion of groups and societies, it is perhaps not strange that various popular media such as television talk

shows, fashion magazines, and self-help experts have made big business of telling people what is needed to reach relationship nirvana. Likewise, it is understandable that the public targeted by these media is hungry for information and opinion—for great power can be gained from information that truly facilitates relationship success. However, this can only be the case if self-help and media advice is based on valid evidence. This entry briefly explores the nature and quality of self-help advice available to consumers of mass media.

Although rigorous analysis of the content of self-help and media advice about relationships is lacking, much can be learned from anecdotally exploring the messages portrayed in prototypic media outlets. Indeed, a survey of television talk show and self-help-focused programming, popular magazines, and self-help literature reveal both some interesting common trends and distinct differences. It is clear that advice in popular media is dominated first by a focus on romantic relationships and second by child–parent relationships. For these reasons this entry focuses on these forms.

Most media advice regarding romantic relationships overestimates differences between men and women, with pervasive stereotypes of men as autonomous and withdrawing from intimacy and women as anxious and emotional. Although gender differences do occur and need to be considered, research has demonstrated that gender differences tend to be fairly small in comparison to differences attributable to the stage of the relationship (e.g., attraction, initiation, long-term), to interpersonal processes (e.g., communication and attribution styles), and to other individual traits (e.g., personality differences, emotional intelligence, beliefs and attitudes, attachment styles). Yet a common thread across much popular advice is the clear impression that men and women approach romantic relationships from extremely different viewpoints. The problem with this assumption is that, although there are gender differences in research that studies averages across groups of men or women, it is fallacious to give practical advice on this basis about how to relate to any one particular individual man or woman. Although there is some truth to stereotypes about men and women's relationship behaviors, the likelihood is great that any particular individual will differ substantially from the stereotype.

Titles of commonly found self-help literature such as *How to Get a Guy by Thinking Like One*, *How to Talk to Women*, and *Why Men Never Remember and Women Never Forget* emphasize the notion of differences between the sexes and leave the impression that there are correct ways to understand the different motives of men versus women. Furthermore, the image of a battle between the sexes is conjured up with titles such as *101 Lies Men Tell Women* and *7 Things He'll Never Tell You*. Media targeting men seem to perpetuate stereotypes of women as sex objects and gold-diggers who are needy and vulnerable, whereas media targeting women perpetuate stereotypes of men as sex-crazed, deceitful, and emotionally closed and immature. This notion that people are usually calculating and disingenuous in romantic relationships, especially men, seems particularly prevalent. Advice is often given on how to “beat” the opposite gender by preempting their motives. Some self-help literature goes as far as to propagate the idea that the only way to “stay ahead” in relationships is to learn how to read into what your partner really wants or to interpret what it means when he or she behaves a certain way. Even such potentially dangerous ideas as “women really mean yes when they say no” and women can “change their men” are sometimes embraced in self-help media. The pervasive stereotype in popular media is that men are not emotionally developed enough to deal forthrightly with relationships and hence need to be guided and coached by women. Relationship research however indicates that the practice of such misguided advice will most likely be problematic.

Ironically, by perpetuating these and similar stereotypes, much popular self-help advice emphasizes ideas that may do more harm than good. Relationship research suggests that ideas such as “men and women differ greatly in their personalities and relationship needs,” “either people are meant for each other or they are not,” and “if you love me you'll understand what I need without me telling you” are not only contra-indicated as predictors of successful relationship functioning and individual happiness but are also typically endorsed by distressed couples who seek therapeutic intervention. Even more ironic, what is often lacking in media advice is the basic notion of honesty and open communication without preconceived motives about reading too much into partners' behavior.

Although much self-help and media advice about relationships is inconsistent with or over-generalizes findings from relationship research, there is television programming and literature that focuses less on stereotypes about gender differences and more on processes involved in relationship formation and maintenance. This literature seems more in-line with general scientific findings, outlining processes that occur in relationships at various stages across the life span and focusing on practical solutions for various problems when they occur (e.g., how to deal with lack of time in a busy world; what to consider before marriage or parenthood). Likewise, some talk-show television programs advise couples to seek professional counseling to resolve issues stemming from differences in communication style, problems with self-esteem, or lack of trust. Even these forms of self-help, however, occasionally propagate stereotyped norms of relationships. The advice seems to ignore the plurality of sexual and relationship orientations as well as the complex nature of most modern-day families.

In contrast to advice about romantic relationships, self-help and media advice regarding relationships between parents and children generally seem more in-line with developmental research. In particular, much self-help literature describes the development of the mother–infant bond and the maintenance of healthy bonding throughout childhood. Such literature tends to be sound in its practical advice. However, some reality television programs overdramatize the troubles of monster children with suggestions for draconian tough-love Super-Nanny tactics for parents to emulate.

In conclusion, rigorous content analyses of media depictions of relationships are needed. Little is known about the effects of self-help and media advice on the consumer. Ironically, if the anecdotal observations presented here are correct, then one might expect the cultivation of or reinforcement of themes found in self-help advice to be more harmful than helpful.

AFFECTION AND AFFECTIONATE BEHAVIOR

Love and affection are often regarded as fundamental human needs. The expression of affection is vital to both the development and maintenance of personal relationships. Although affection and affectionate communication (also called affectionate expression) are related experiences, they are not synonymous terms. Affection is an internal psychological state of positive, often intimate regard for another. Thus, affection is a positive feeling or emotional disposition toward another that does not necessarily include the expression of these feelings. Affectionate communication is defined as an individual's enactment or expression of feelings of closeness, care, and fondness for another. Thus, affectionate communication is the enactment of behaviors (e.g., hugging, kissing, saying "I love you") that portray or enact feelings of affection. However, the expression of affection is separate from feelings of affection, as it is possible to feel affection without expressing affection and to express affection without feeling it. Often times in initial romantic relationships one might not express strong feelings of affection verbally (i.e., "I love you") for fear of scaring the other person away. Conversely, partners in a strained marriage might say the words "I love you" without truly feeling affection for one another.

This entry distinguishes affectionate communication from other related experiences, discusses the factors that affectionate communication is related to, and explores the benefits of affectionate communication for both relational and physical health.

Conceptualization and Measurement

Affection is thought to be distinct from other positive relational experiences such as intimacy. Affection is characterized by a sense of liking, positive feelings, and high regard for another. Intimacy, in contrast, involves a sense of interdependence between people who rely on each other to fulfill needs. Another key difference between the concepts is that affection is an individual level variable and intimacy is a relational variable. Although conceptually different, affection and intimacy are often interrelated as high levels of affection, and the expression of those feelings can often lead to increases in intimacy in the relationship and vice versa. Furthermore, some statements and behaviors can communicate both intimacy and affection concurrently.

Affection can be expressed in a number of different ways. Researchers have claimed that affectionate expressions can be grouped into three distinct subdimensions: *verbal*, *nonverbal*, and *support* affection.

Verbal affection includes the use of language (spoken or written) to convey affectionate feelings for another. Some of these messages express the sender's feelings for the receiver, such as "I like you" or "I love you." Other messages can help form or affirm the current status of the relationship, such as "You're my best friend" or "I care about you more than any person in my life." Others affirm future hopes for the relationship, such as "I hope we will be together forever." Finally, other statements express the value of the relationship by stressing how the sender would feel without it, such as "I would be so sad if I couldn't see you." Verbal affection is unique from other forms of affectionate behaviors because of the use of language. Often, people use verbal forms of affection (rather than nonverbal forms) when they wish to be clear and reduce the chance of misinterpretation.

Nonverbal affection includes behaviors, not including language, that express affectionate feelings. Nonverbal displays of affection can vary in nature and interpretation. Nonverbal displays of affection are thought to be under less conscious control and thus are assumed to more accurately reflect the emotional state of the sender than verbal cues. Common nonverbal expressions of affection

can include, but are not limited to, facial behaviors (e.g., smiling, winking, and eye contact), touch (e.g., kissing, hugging, and holding hands), vocalic behaviors (e.g., heightened pitch and baby talk), and shared physical proximity. Compared to verbal affection, understanding nonverbal affection is more complex and difficult because the meaning is often more ambiguous than that of verbal statements.

Finally, support affection includes behaviors that provide social, psychological, emotional, or instrumental support. These behaviors convey affection indirectly through some provision of assistance and/or by fulfilling needs. Example of support affection could include providing a sympathetic ear to a friend going through a hard time with a relational partner, taking care of yard work for a friend who is a single parent, or offering money to a brother who just lost his job. One difficulty with support affection is sometimes these behaviors have no affectionate connotations. Thus, the recipient (or a third-party onlooker) may overlook or not understand that these behaviors are meant to express affection. For example, a husband may fill the gas tank and wash his wife's car because she has been particularly busy lately. However, the wife might not recognize this instrumental display of support because of its indirect nature. Consequently, certain forms of support affection can be easily overlooked.

The dimensions of verbal, nonverbal, and support affection can vary greatly in their intensity. Verbal statements such as "I like you" and "I'm in love with you" are similar in that they both convey feelings of positive regard and care for another; however, they vary greatly in the degree of affectionate feelings they express. Similarly, a kiss can range from a nonintense peck on the cheek to a prolonged open-mouthed kiss. Finally, support affection can vary in the intensity of the help that is given. For example, giving a friend a ride to work when his or her car breaks down is less intense than giving him or her \$1,000 to help get his car fixed. One study examined the intensity of verbal and nonverbal displays of affection. The verbal statement "I love you" and the nonverbal behavior of a kiss on the lips were considered to be the most intense behaviors, whereas the verbal statement "I admire you" and the nonverbal behavior of shaking hands were considered to be the least intense affectionate behaviors.

Although affectionate communication is a physical or behavioral event, it is often measured using self-report methods, as some affectionate behaviors are difficult to observe. Typical methods for measuring affectionate behavior often ask people to rate their own or others' amount of affectionate behaviors. For example, people might rate how often they say "I love you," give a hug to a particular loved one, or engage in support behaviors such as helping with problems or giving praise.

Affectionate communication has also been measured as a trait-level variable for both affection given and affection received. Trait affection-given measures the extent to which one is, by nature, an affectionate person ("Anyone who knows me well would say that I'm pretty affectionate"), whereas trait affection-received measures a person's tendencies to receive affectionate expressions from others ("People are always telling me that they like me, love me, or care about me").

Influences on Affectionate Communication

Individual, relational, and contextual factors, such as biological sex, sex composition of the relationship, gender, relationship type, relationship stage, and even the public or private setting, have been found to influence how affection is expressed.

Numerous studies have examined the influence of biological sex on affectionate communication, and nearly all have found that women are more verbally and nonverbally affectionate than men. However, researchers have found that men are less affectionate than women in same-sex relationships, but no difference appears in opposite-sex relationships. Furthermore, it appears that in male-male relationships support affection is more commonly expressed than verbal or nonverbal forms of affection.

Some studies have examined the extent to which gender influences affectionate expressions. Gender refers to a person's psychological sex-role orientation (masculine and feminine) rather than to his or her biological sex. In father-son relationships, sons' femininity was positively associated with their expression of nonverbal and supportive affection, and fathers' femininity was positively related to the expression of supportive affection.

This same study found that sons' masculinity was also positively related to their expression of nonverbal affection, and fathers' masculinity was positively related to their expression of verbal, nonverbal, and supportive affection. The relationship between masculinity and affection was unexpected, as one would not necessarily expect that masculine qualities (such as aggression and competitiveness) would be positively related to affectionate behaviors. However, three other studies have replicated links between masculinity and affectionate communication (some using a different measure of gender) in other relationships such as cross-sex adult platonic relationship and sibling relationships. Consequently, it appears that the relationship between masculinity and affectionate communication is not an artifact of the measurements or the relationship being studied. Unfortunately, no satisfactory explanation exists for this relationship between affectionate communication and masculinity.

Relationship type also appears to influence the amount and type of affectionate communication. In relationships with parents, people were most likely to communicate affection through support affection, less likely to communicate affection through verbal channels, and finally, least likely to communicate affection through nonverbal behavior. In addition, women reported being more affectionate, in all three affectionate types, with their parents than men do.

Studies examining father-son relationships that compared differences between biological and nonbiological sons (adopted and stepchildren) found that fathers reported expressing more nonverbal and support affection to biological sons and adoptive sons than with stepsons. However, in this regard, biological and adoptive sons did not differ from each other.

Differences in affectionate expression are also seen during the different stages of relationships. In the initial stages of romantic relationships, affectionate expressions often serve as critical incidents (e.g., first kiss, saying "I love you" for the first time) by which relational growth is gauged. Conversely, in established relationships, the lack of affectionate behavior is often used (and understood) as an indication of relationship de-escalation and deterioration. Consequently, changes in affectionate behavior often serve as turning points by

which relational development or deterioration can be judged.

Finally, contextual characteristics, such as a public or private setting, can influence the amount and type of affection expressed. Baby talk was used more often in private settings to express affection to friends than in public. However, other research has shown that with friends and siblings affectionate behaviors were judged to be more appropriate in a public setting than in a private one. These differences can be understood by the risk factors associated with expressing affection. Sometimes expressing affection in public may be more risky than expressing it in private, whereas in other cases the opposite might be true. For example, someone might be more likely to express romantic affection to a friend in a private setting than in a public setting because it cannot be seen and heard by others.

Benefits of Expressing and Receiving Affection

The benefits of receiving affection have been well documented. Receiving affection contributes to overall mental health, physical well-being, self-esteem, and life satisfaction. Other studies have shown that affection is inversely associated with depression and loneliness. In social relationships, affection is related to a range of relational benefits, including closeness, love, and relational satisfaction in marriages, parent-child relationships, and friendships.

In examining affection as a trait variable, those who were highly affectionate communicators were more self-assured, more comfortable with closeness and intimacy, were happier and in better mental health, and were less stressed and depressed than low-affection communicators. In spite of these findings, it is difficult to determine if the positive effects of expressing affection are different than the effects of receiving affection. One study found that after controlling for affection received, expressing affection was associated with increased happiness and self-esteem, higher relational satisfaction, decreased fear of intimacy, and decreased risk of depression.

Expressing affection also appears to have important physical benefits. Expressing affection

has been related to lower resting heart rate, blood pressure, and other physiological measures. Expressing affection through writing helps reduce the stress response by accelerating the recovery of the stress hormone cortisol to baseline levels. Furthermore, affectionate writing (e.g., writing about how much one cares and loves another) has been found to reduce total cholesterol in two separate trials. Thus, research indicates that the benefits of expressing affection are separate and distinct from the benefits of receiving affection.

AFFILIATION

This entry reviews theory and research on affiliation, which is the broad class of behaviors that humans and other animals use to initiate and maintain pair bonds, kin relations, resource-trading alliances, friendships, and other kinds of relationships. Like their hominid ancestors, humans are deeply social and have benefitted from affiliation as a means of fulfilling a variety of needs. The motivation to affiliate is shaped by both personal characteristics and features of situations. An interaction partner's personality traits can make affiliation difficult, and social exclusion is a pervasive feature of social living. Under some circumstances, social exclusion can increase affiliation; under others, it can lead to poor judgment and antisocial behavior.

The Origins of Human Affiliation

Within the environments of human and hominid predecessors, social living made it much easier for these ancestors to fulfill their most basic needs. Natural selection has thus favored social tendencies among humans, and today people possess affiliative adaptations that evolved tens of thousands of years ago. Human affiliation varies by kind and degree, and different cultures often provide different norms about how people should affiliate, but extensive affiliation in one form or another is typical among all human populations.

Because not all large primates affiliate extensively with each other (e.g., chimpanzees, bonobos, and gorillas are more social than orangutans), it is worth considering why group living was advantageous to these ancestors. After all, affiliative living certainly has its risks, as cases of divorce, domestic violence, and gang warfare remind us. These risks, however, are heavily outweighed by the benefits of affiliation. Hominids living in groups had a much easier time protecting themselves from predators, hunting large mammals, and finding valued resources than they would have had they lived primarily in solitude. Group living also allowed some hominids to easily communicate with and learn from each other so that the "secrets" of adapting to particular environments could be quickly learned. Perhaps most importantly, group living

typically made hominid reproduction easier and more successful because mates were nearby and the group provided greater protection to offspring. These and other benefits help explain why most of the large primates have met the challenges of their environments by clustering into groups. Only in very few environments (such as the orangutan's) is minimal affiliation an adaptive way of living.

Selective Affiliation

Social as they are, however, humans are not indiscriminate in their affiliative tendencies. All human beings prefer to affiliate with some types of people more than others. Donald Brown, an anthropologist who has compiled an extensive list of pancultural human characteristics, has noted that in all cultures people prefer ingroup members over outgroup members. Bias favoring ingroup members takes on different forms in different lands, but all normal humans generally prefer people of their own kind (e.g., people of similar heritage, opinion, or purpose) over people from other groups. There are certainly some exceptions to this tendency (e.g., attraction to the opposite sex, nondiscriminatory employment recruiting), but preferring people who are "us" over people who are "them" seems to be a basic characteristic of human nature.

One reason humans prefer people of their own kind over others is that to remain safe, animals in general must be cautious around unfamiliar objects. An animal that patiently observes a peculiar intruder before deciding whether or not to approach the intruder significantly diminishes the risk of getting injured or killed. And because in some environments other people are the most dangerous objects present, it is sometimes prudent to regard people from an outgroup with suspicion.

But humans consider much more than group membership when choosing their interaction partners. Other people widely vary in their characteristics (e.g., some are more attractive, generous, or conscientious than others), and people seem to take these characteristics into account as they initiate and manage their relationships. Precisely which characteristics are preferred in an interaction partner often depends on the context because a given characteristic (such as empathy) might be much more important in some kinds of relationships

(such as in friendship) than others (such as in a work relationship).

One important characteristic that people seem to value in all kinds of relationships is trustworthiness. According to the sociofunctional perspective, trustworthiness is the most valued of all characteristics because humans depend on each other to meet their needs and often exchange valued resources in an asynchronous way (e.g., Catherine shares her knowledge with Steven today with the expectation that Steven will reciprocate some time in the future). A person who does not seem trustworthy should therefore be avoided because such a person may be a drain on others' resources. Consistent with this perspective, numerous studies suggest that trustworthiness is one of the most, if not the most, prized characteristics of an ideal interaction partner. These studies have been conducted primarily in North America, but because human living everywhere is characterized by resource exchanges, it is highly likely that trustworthy interaction partners are strongly preferred in all cultures.

The Motive to Affiliate

Many behavioral scientists have studied affiliation as a human motive. Although the desire to affiliate with others is part of human nature, there are of course some people who are more highly motivated to participate in social interactions than others. Henry Murray, a personality psychologist who studied this difference among people, noted that people with a high need for affiliation tend to be friendly, outgoing, cooperative, and eager to join groups. People with a low need for affiliation tend to be less friendly, more reserved, and aloof. Although it is tempting to think of a high need for affiliation as a personal asset, there may be some costs to having a high rather than low need for affiliation. People with a high need for affiliation tend to be conforming, whether others around them are behaving wisely or not. And under some circumstances, people with a high need for affiliation may have difficulty disengaging from social interaction in order to get tasks done.

In more recent work on individual differences in affiliation motivation, researchers have become interested in the different ways people strive to affiliate. In this line of research, it is recognized

that people with a high need for affiliation may differ from one another because they have different reasons for wanting to interact with others or different ways of interacting. Some people may have a strong need for affiliation because they find social activities intrinsically satisfying. People like this tend to enjoy parties, socializing with friends, and similar activities simply because they experience pleasurable feelings in these situations. Other people, however, may have a strong affiliation motivation because they like to get attention and impress people, because they want support from others during difficult times, or because they like to compare themselves to others and learn from the comparison. People with a strong affiliation motivation may also be differentiated on whether they are primarily motivated to experience intimacy (i.e., close interaction with others) or power (i.e., dominating, influential behavior toward others). Thus, depending on other aspects of a person's personality, affiliation motivation can express itself in a variety of ways.

Affiliation and Belonging

The need to belong (a fundamental desire to experience close and lasting relationships with others) differs from the need for affiliation because the need to belong is a universal human need rather than a component of personality. Because it is a basic need, when people succeed in fulfilling their need to belong, they experience a higher quality of life. Numerous studies demonstrate that people who maintain at least a minimum quantity of enduring, healthy relationships experience less emotional distress, cope better with adversity, and have fewer health problems.

However, not all affiliative behavior allows people to fulfill their need to belong. Merely living and working in a crowded city, for example, may not protect a person from feeling lonely. Brief, superficial interactions tend to be ineffective in building strong relationships with others, and as a consequence, such behavior may leave a person's need to belong unsatisfied. The full positive consequences of affiliating with others can only be achieved when people affiliate with others in a way that builds and strengthens relationships that are meaningful and lasting.

Although the need to belong (which is present in all people) differs from the need for affiliation (which varies in nature and strength between people), a person's need for affiliation may influence the degree to which his or her need to belong is fulfilled. For example, many people with a high need for affiliation may have an easier time fulfilling their need to belong because the formation and maintenance of strong relationships requires affiliation. It might be reasonable to expect, therefore, that people with a higher need for affiliation would be happier than people with a lower need for affiliation, and in fact, research studies confirm that sociable people tend to be happier.

Personality Influences on Affiliative Behavior

Research on the need for affiliation provides an important reminder of the fact that personality plays a significant role in affiliative behavior. The personality trait that most people know as extraversion, for example, can affect a wide variety of affiliative behaviors. Extraversion is characterized not only by gregariousness but also by interpersonal warmth, assertiveness, a high activity level, and a tendency to seek excitement. Extraverts also experience greater happiness than introverts do, due in part, perhaps, to the fact that their sociability and warmth make it easier for them to fulfill their need to belong. Numerous studies suggest that people's relative level of extraversion or introversion endures across the life span and is substantially influenced by genes. Life experiences probably also shape people's level of extraversion to some degree, but in general, most adults today are about as extraverted as they were 10 years ago.

Another personality trait that has a substantial impact on affiliative behaviors is agreeableness. Like extraversion, agreeableness is also genetically influenced and relatively stable over the life span. It is characterized by altruistic tendencies, modesty, empathy, compliance with others' wishes, and straightforwardness (or sincerity). Agreeable people also tend to be highly trustworthy, which (for reasons explained earlier) should make them much more likable to those around them. In general, highly agreeable people have tendencies similar to those that many people would describe as the characteristics of an ideal friend.

Just as high levels of extraversion and agreeableness may facilitate affiliation, other heritable personality attributes may inhibit affiliation in long-term relationships. For instance, both schizoid personality disorder and schizotypal personality disorder are characterized by a lack of interest in social activity. Other personality disorders (which do not necessarily involve a lack of interest in affiliation) are characterized by difficult behaviors that harm long-term relationships. People with antisocial personality disorder, for example, tend to be nonconforming, reckless, nonempathic, and deceitful. Those with narcissistic personality disorder tend to have an inflated sense of personal entitlement, show little empathy toward others, and act arrogantly. People with borderline personality disorder tend to have highly unstable beliefs about their relationships (e.g., "I love you" this morning, but "I hate you" this afternoon) as well as unstable moods and intense worries about abandonment. These disorders do not constitute the full list of all personal attributes that can be detrimental to human relationships. But they do emphasize that people's personalities, which are often difficult to change, have a substantial impact on affiliative behaviors and relationship quality.

Sex Differences in Affiliative Behavior

Researchers have consistently observed certain sex differences in affiliative behavior. These differences are not large (i.e., the difference between the average man and the average woman is small compared to the differences among people within each sex), but the differences have emerged consistently in many studies performed in a variety of cultures. On personality tests, women score higher than men on enjoyment of social interaction. Women also tend to score higher on all components of agreeableness, which suggests that people might find the average woman a little easier to get along with than the average man. On the other hand, men tend to score higher in assertiveness and dominance, which suggests that in many circumstances men may be quicker to initiate interactions with people and to direct groups.

Because personality tests often depend on people describing themselves, it is common to wonder whether gender differences in personality test scores

might merely reflect differences in self-concept rather than in differences in personality. After all, girls are often expected to be gregarious and kind, and boys are often expected to be directive and self-confident, and these expectations may affect how people view themselves more than they affect actual behavior. However, there are several reasons to believe that the gender differences that emerge in test scores are true personality differences and not just differences in how men and women describe themselves. First, as mentioned above, the gender differences described have emerged in many different cultures. This similarity is important because cultures have varying expectations about how men and women are supposed to act. Countries vary in their emphasis on gender equality, for example, but surprisingly, more egalitarian countries tend not to produce smaller gender differences on personality tests than less egalitarian countries. In addition, some of the gender differences described above have been observed in the behavior of very young children who have had little time to learn (and perhaps little interest in learning) how their culture expects them to act. Current research thus suggests that the differences that have been observed in men's and women's personality test scores reflect genuine differences in behavior.

Another interesting way in which men and women's affiliative tendencies differ is in their preferences to affiliate with different sized groups. Specifically, a variety of studies suggest that among children as well as among young adults, females generally prefer to affiliate in dyads (i.e., one-on-one), whereas males generally prefer to affiliate in larger groups. These studies are consistent with evidence that young boys tend to have larger social networks than young girls. One reasonable explanation for these sex differences is that females are somewhat more oriented toward intimate affiliation, whereas males are somewhat more oriented toward exercising power (which can be more substantially enhanced in larger groups). Research with adults generally supports this perspective, although it also suggests that there are some situations in which these sex differences do not hold.

Situational Influences on Affiliative Behavior

Personality and gender are not the only influences on affiliative tendencies. People experience highs

and lows in their desire to affiliate, and these fluctuations are often determined by the situations in which people find themselves. For example, people are more motivated to affiliate with others when they are stressed or afraid. This effect can emerge even when stressed people are around complete strangers, such as in a hospital waiting room.

Another event that seems to amplify the motivation to affiliate is social exclusion. Experiments have shown that when people feel ostracized, rejected, or worried about living a lonely life, they often exhibit stronger affiliative tendencies. This increased desire to affiliate may be expressed by acting in highly conforming ways, by expressing a greater interest in making new friends, by seeking out current friends, or by behaving in positive ways toward potential interaction partners. However, people seem to be strategic in their affiliative behaviors following social exclusion. They do not typically try to affiliate with the people who initially rejected them, and they do not try to affiliate with others if they doubt that others will like them. Instead, rejected people seem to desire affiliation only with people who might have a reasonable chance of accepting them.

Negative Consequences of Disaffiliation

Recently, behavioral scientists have begun to examine some of the negative consequences of social exclusion or disaffiliation. One neuroscience experiment has shown that when people are prevented from affiliating with their peers during a simulated ball-tossing game, they experience greater neural activity in the anterior cingulate cortex and the right ventral prefrontal cortex, brain regions that typically become activated when people experience pain. Other experiments have shown that peer rejection can cause a decrease in self-esteem, a decrease in reasoning ability, an increase in aggression, and even an increase in unwise risk taking. In many circumstances, then, disaffiliation can cause maladaptive and antisocial behavior. But as previously noted, a more positive way that people can cope with rejection is to seek affiliation with others who might be more accepting.

AFFILIATION IN NONHUMAN ANIMALS

Humans are not the only species to form affiliative relationships. Affiliative behavior similar to

what is seen in human beings is common throughout nonhuman animals from primates through invertebrates. However, since researchers cannot obtain verbal reports from other species, they must use a variety of behavioral and physiological assays to infer affiliative relationships. Furthermore, the diversity of relationships in other species allows researchers to understand more fully the variety of affiliative relationships available to human beings and can provide specific suggestions for why certain relationships occur. This entry provides a review of current research on affiliative behavior in nonhuman animals.

Measuring Affiliation in Other Species

A common measure of affiliation is simply time spent together. If two organisms have a choice of several potential companions and consistently select particular individuals for association, this hints at some affiliative relationship. More specific behavioral measures can include frequency or duration of direct physical contact, such as huddling or grooming behavior (i.e., when one individual combs through the feathers or hair of another using its beak, claws, mouth, or fingers). Nonconceptive sex or mounting behavior may also indicate affiliation. Animals with close social affiliations may mark the relationship through shared songs or calls, as is seen in many birds; through learning the partner's signature whistle, as in dolphins; or converging on a mutual variation of a call type, as seen in bats and some nonhuman primates.

Separation and reunion tests provide information on the emotional component of affiliation. Increased vocalizations or increased agitation when separated from a specific individual and increased affiliative behavior (compared to baseline) following a reunion can index the strength of a relationship. Comparing the reaction of an animal placed in a novel environment with or without its partner illustrates the potential stress-reducing effect of an affiliative relationship. Exposing a young individual to a fear-inducing stimulus and noting the social response can indicate the preferred partner of the young.

Several physiological markers can measure affiliation. Grooming behavior in talapoin monkeys has been shown to increase levels of naturally

occurring opiates secreted within the brain. Touching, grooming, and sexual interactions can lead to increased levels of oxytocin, a peptide hormone previously thought to be involved only in uterine contractions and nursing but is now known to be an important hormone in adult pair-bonding for socially monogamous animals (such as prairie voles, small monogamous rodents) and for parent-offspring relationships. Glucocorticoids (cortisol and corticosterone) secreted from the adrenal gland are associated with both physical and psychological stress, and affiliative relationships can modulate these hormones. Pair-bonded monkeys display much lower agitation and cortisol levels when they are with their partner in a novel environment, and hearing recordings of the vocalizations of partners can reduce the physiological response.

Varieties of Affiliative Experience

Affiliation patterns vary as a function of the social structure and kinship structure of different species. The affiliative relationships that are of greatest value are those that will lead to the greatest reproductive success, which can be measured both by the number of offspring of an individual that survive to reproduce and through the number of relatives that are reproductively successful. Thus, affiliation with close kin should lead to higher reproductive output either for the individual and/or any close relatives. Kinship structure varies in different species. In some species, such as most Old World monkeys (baboons, macaques) and many other mammals, males migrate and females remain in the natal group, meaning that there will be female kin in the group. In other species, such as chimpanzees and many New World monkeys, males stay in the natal group and females leave, creating a high potential for male kin relationships. In some cases, related males migrate together, as in lions, so that a lion pride typically has several closely related females and several closely related males.

Affiliative relationships may also emerge between unrelated individuals when there is mutual benefit in the relationship. An obvious example is the shared interests of mothers and fathers in infant survival. However, coalitions of unrelated

animals may lead to increased success for both. For example, dolphin males are rarely successful alone in mating with a female. However, two or more males will form a coalition, and through this coalition, they will be more successful. Each male's chance of conceiving an offspring rises from 0 to 50 percent as a result of forming a relationship with another male.

Species also differ in parental care patterns. In some species, females may mate with many males, and a male with low certainty of paternity should gain little from extensive involvement in infant care. In this case, parenting is done by the mother alone or is shared with her female kin. In contrast, males in species that form pair bonds and maintain social monogamy have a greater certainty of paternity, and these males are often active participants in infant care.

Parent-offspring affiliation. A mother-infant bond is generally perceived as the most basic of affiliative relationships. In species where females are the primary caregivers, this is expected. However, infants may also develop relationships with other related female caregivers in species where female relatives stay together. Of greater interest are the species where the primary caretaker is the father or the father and older siblings. In the titi monkey, a small pair-bonded species from South America, fathers are the main caretakers, although mothers must provide food through nursing. When infants are given a choice between the mother and the father, they choose to associate with the father. Curiously, mothers choose to associate with fathers rather than with their infants. In cooperatively breeding species where individuals in addition to the father assist in parental care, a juvenile, when frightened, runs to the individual that had carried it the most when it was an infant, never to its mother. Thus, affiliative patterns between parents and offspring vary with the type of parenting system.

Heterosexual affiliation. Although close heterosexual relationships are considered common for humans and are very common among birds, close heterosexual affiliations are relatively rare among mammals, and they are generally confined to species with some form of social monogamy and biparental care. Comparative studies on closely

related rodent species have shown major differences in heterosexual affiliation as a function of the social system. In monogamous prairie voles, a long-term affiliative relationship forms that is mediated by increased levels of oxytocin in females and by arginine vasopressin (another small peptide hormone) in males. The closely related montane voles are polygamous, do not form pair bonds, and are minimally affected by manipulations of oxytocin or vasopressin. California mice are also monogamous, and males are involved in infant care and defense of the mate and show high levels of vasopressin compared to polygamous white-footed mice where males do no parental care and do not form long-term relationships.

Separation and reunion studies have demonstrated increased behavioral agitation and stress hormones in pair-bonded monkeys, and these primates also cooperatively defend the relationship with aggression toward same-sex intruders. Although mates actively cooperate in defense against intruders, when individuals are tested alone, they may respond positively to a stranger of the opposite sex. In common marmosets, a socially monogamous monkey, single males and paired males without offspring, showed an interest in odors from novel, ovulating females and displayed an increase in blood testosterone within 30 minutes of the first exposure to the female's odor. In contrast, males with infants (fathers) were not interested in the scents and displayed no changes in testosterone, suggesting that affiliative relationships with a mate may increase when both care for infants.

Within-sex affiliation. Kinship relationships can predict the nature of within-sex affiliation. Thus in species where males disperse and females remain in the natal group, there is evidence of close associations between female kin. Females within a matriline interact more with each other than with females from other matriline. They will assist each other in caring for infants, and if one member of the matriline is attacked, other sisters are likely to retaliate to other members of the attacker's matriline. In these species, sisterhood is powerful. In species where females disperse and males remain in the natal group, males are more likely to be related to each other and to show affiliative behavior. The woolly spider monkey, or muriqui, from Brazil is one of these patrilocal species and is

noteworthy for showing no evidence of aggression or dominance behavior within the group. When a female is in estrous, males line up to wait their turn to mate, and when aroused or anxious, males engage in group hugs with lots of vocalization. Thus, males, at least in some species, can form close affiliations.

Strong affiliative relationships are not unique to humans, and the diversity of affiliative relationships among nonhuman species and the ability to study developmental and physiological aspects of relationships under carefully controlled conditions make nonhuman animals important models for understanding human affiliative relationships.

AFFINITY SEEKING

There is a long history of research looking at what makes people find others socially attractive—what makes people like each other. For many years, most predictors of attraction or affinity were static variables such as attitude similarity, proximity, and appearance. Thus, in Donn Byrne's work, people were given the presumed attitudes of a target person and then asked to indicate how attractive they found the target. In research on propinquity, scholars examined how closely people

lived or worked with one another and then correlated those distances to attraction.

The affinity-seeking construct, developed by Robert Bell and John Daly, offered a more integrative, active approach to this body of literature. Early research on the construct had two primary themes. The first was a presumption that people engage in specific, active, and planned behaviors to get others to like them. So the construct suggested that people seeking affinity with others would, for example, intentionally find and suggest things they had in common with others, would physically move closer to people they were attracted to, and would actively change their physical appearance to make themselves more attractive. The second theme involved cataloging the primary strategies people use when actively seeking affinity. To do that required a conceptual model that highlighted four components of affinity-seeking: (1) antecedent factors (such as the goals involved in seeking affinity—to persuade, to generate liking), (2) constraints (variables that might affect affinity-seeking attempts such as personality, social skills, and context), (3) affinity moves (specific affinity-seeking strategies), and (4) responses (reactions of the target such as ignoring and/or rejecting the attempt).

The bulk of the academic work done on the construct focuses on the third component—specific affinity moves people make when attempting to generate positive interpersonal reactions. Bell and Daly discovered 25 different strategies that fell into seven clusters: (1) control and visibility (e.g., being interesting and dynamic), (2) trust (e.g., demonstrating openness and trustworthiness), (3) politeness (e.g., letting the other have control over the conversation, following conversational norms), (4) concern and caring (e.g., supporting the other's sense of who he or she is, acting attentive and listening), (5) other-involvement (e.g., incorporating the other into the exchange, nonverbal immediacy), (6) self-involvement (e.g., showing a sense of closeness with the other, including oneself in the conversation), and (7) commonalities (e.g., emphasizing similarities with target, assuming equality). A cluster analysis of the 25 strategies found they fell along three continua: (1) active-passive (being dynamic vs. listening), (2) aggressive–nonaggressive (manipulating attractiveness vs. supportiveness), and (3) self-other orientation (taking control versus including other).

The affinity-seeking construct spawned a number of lines of research including work on affinity-maintenance in married couples, affinity-seeking skills (conceived of as an individual difference), and the correlates of affinity-seeking.

Affinity Maintenance

Robert Bell, John Daly, and Maria Cristina Gonzalez introduced the notion of affinity-maintenance strategies: ways married couples actively and intentionally maintain positive feelings for one another. In their research, they identified 28 common strategies including most of the original Bell and Daly strategies and six new affinity-maintenance strategies: faithfulness, honesty, physical affection, verbal affection, self-improvement, and third-party relations. All of the 28 strategies were correlated with marital quality, and women felt they engaged in most of the strategies more frequently than men.

Research on affinity-maintenance strategies was adopted by scholars and later renamed and reconceptualized as relational maintenance behaviors. In addition to examining affinity maintenance in marriage, researchers have studied the affinity-seeking strategies of stepparents. Scholars also have suggested that people test others' affinity. For instance, William Douglas described tests such as networking, approaching, withdrawing, confronting, sustaining, hazing, and diminishing oneself.

Affinity-Seeking Skills and Correlates

A number of researchers have conceptualized affinity-seeking as an individual difference, arguing that people vary in their ability to actively get others to like them. Not surprisingly, people who report, or are seen by others as, being better at affinity-seeking are more positively regarded than their counterparts who are not as skilled at affinity-seeking. Children's satisfaction with their stepparents is positively correlated with their perceptions that their stepparents use more active affinity strategies. This association between affinity moves and satisfaction is also true in classrooms where students prefer and respond more positively to teachers who enact more and use a

greater variety of affinity strategies. Students also report being more motivated to study for teachers who engage in more affinity-seeking. Similarly, in the workplace, subordinates experience greater job satisfaction when their supervisors are viewed as engaging in more affinity-seeking. Further, individuals who report using a wider variety of strategies are better liked than those who habitually use a limited number. Falling into the habit of using only a few strategies not only makes people boring but also limits their communicative effectiveness.

In terms of correlates, affinity-seeking is positively and significantly associated with extraversion, assertiveness, and interaction involvement and inversely and significantly related to communication apprehension, verbal aggressiveness, loneliness, and neuroticism. At a more granular level, the associations between the use of individuals' tendency to employ particular strategies and various personality variables is often complex (e.g., assertiveness is positively related with active moves such as dynamism and negatively associated with passive moves such as conceding control). The use of specific strategies also varies by stage of the relationship, age, target, and gender (e.g., women report using listening, physical attraction, sensitivity, and elicitation of others' disclosure more than men, while men report more frequently using assuming control and presenting an interesting self).

AFFIRMATION

The concept of affirmation describes a process by which people develop into the person they want to become (termed the *ideal self*) with the assistance of close relationship partners. Researchers who study affirmation assume that who a person is currently and who a person would like to become do not merge automatically and in isolation from others. Rather, identities are shaped by interaction with intimate partners. This entry describes two important manifestations of affirmation. The first, the so-called Michelangelo phenomenon, describes how relationship partners assist in self-development. The second form, developed out of a tradition of self-affirmation theory, describes how implied assistance from relationships, through largely mental, unconscious processes, assists in healthy self-development.

Michelangelo Phenomenon

The term *Michelangelo phenomenon* was coined by Caryl Rusbult and her colleagues to describe the process by which close relationship partners help sculpt the self into one's ideal form—the person whom one aspires to be. Two important subprocesses are included. *Perceptual affirmation* describes the degree to which close partners see in oneself a preferred ideal form. In research studies, perceptual

affirmation is measured by endorsement of self-report items such as, “My partner thinks I have the traits and dispositions that I believe are most desirable.” *Behavioral affirmation* describes the degree to which the other behaves toward the self in a manner that facilitates personal progress toward the aspired-to ideal self. This form of affirmation is measured by endorsement of items such as, “My partner helps me become what I ideally want to be—he/she elicits the best in me.” In this tradition, affirmation resembles a self-fulfilling prophecy—when the behavior of close others is aligned with one’s aspirations and personal goals, partner beliefs can become reality and people can progress toward their ideal selves.

One of the ways that perceptual and behavioral affirmation facilitates progress toward one’s ideals is by selecting appropriate situations in which the ideal self can flourish. Because the lives of close partners tend to be mutually intertwined, close relationships influence the situations in which one enters. For example, if a close partner understands one’s desire to be more assertive and if the partner perceives in oneself the possibility of being more assertive, his or her supportive influence may help one enter into situations that provide opportunities to be assertive. Over time, as these situations recur, beliefs, expectations, and skills are bolstered, and actual assertiveness may develop. Perceptual and behavioral affirmation has been shown to increase self-esteem, life satisfaction, and emotional well-being of the developing person, likely because of the partner’s support in moving the actual self toward the ideal self. Consequently, movement toward the ideal self also increases relationship satisfaction between the sculptor and the sculpted.

The opposite can also occur—when close others fail to provide affirmation, or see and behave toward the self differently than one’s ideals—the worst might be brought out. For example, if the partner’s ideal for oneself does not match one’s own ideal, his or her behavior might induce self-development that is antithetical to one’s aspirations. Because affirmation operates in the manner of a self-fulfilling prophecy, one’s incorrect perception and behavior influences situation selection, and consequently, one might not be presented with situations in which assertiveness can be developed. This might also occur when close partners misinterpret one’s goals

and aspirations and instead focus on a secondary or tangential goal (e.g., by focusing on one’s pleasant compromise after a failed negotiation rather than on how one could have utilized assertiveness). Second, partners might also fail to provide support for one’s goals either by ignoring them or, in the worst case, undermining them. In both cases, these failures to affirm are associated with impaired personal development as well as with negative affect and decreased relationship satisfaction between the sculptor and the sculpted.

Close Relationships and Self-Affirmation

A second body of research discusses how close relationships provide affirmation but unlike the Michelangelo phenomenon, without tangible assistance from partners. Research in this area stems from the tradition of self-affirmation research, which proposes that when self-esteem is threatened, people are motivated to restore positive self-worth. This can be done by reminding oneself of an area of personal identity not currently under attack, compensating for the potential threat and thereby maintaining self-esteem. Self-affirmation does not work by simply reminding oneself of one’s overall goodness in a general way; rather, specific areas of identity unrelated to the present threat are unconsciously drawn upon to remind oneself of other positive qualities, thereby restoring feelings of self-worth.

Because close relationships constitute an important component of most people’s identity, relationships may provide self-affirmation during self-esteem dips. Thus, even though relationship partners may not be physically present to provide affirmation, their mental presence may suffice to maintain self-esteem. In one study, being reminded of close, positive relationships changed the way that people interpreted feedback about a failed intelligence test. When people wrote about a close, positive relationship, they were more open to details about their poor performance, presumably to improve their future performance. Research participants who were not reminded of their close, positive relationship appraised the feedback as a reminder of their inadequacies and were less open to potentially useful feedback. More generally, because partner-affirmation helps people construe

challenging situations (e.g., failure) as opportunities for potential growth rather than as threats to be avoided, affirmation tends to foster self-improvement in the form of reduced defensiveness, openness to challenge and failure, increased compassion and altruism, and positive emotionality.

Partner affirmation may also buffer the negative effects of illness. Partner affirmation is associated with reduced self-reported stress, increased coping efficacy, and reduced physiologically measured stress. A sample of patients with breast cancer who were given a self-affirmation writing task showed fewer physical symptoms at a 3-month follow-up appointment. The single most written about topic was close relationships.

Conclusion

Personal movement toward one's ideal self transpires gradually and with affirmation from close relationships. The two forms of affirmation described in this entry, the Michelangelo phenomenon and partner affirmation, illustrate two different ways close partners facilitate personal growth. Although the two processes differ, both show how partners may help promote self-worth and personal development.

AFRICAN-AMERICAN FAMILIES

The recent increase in immigration to the United States of peoples of African descent (i.e., Africans, Caribbean Blacks) has led to a greater percentage of individuals who are labeled Black Americans. There are many similarities among these groups, but their historical relationships and immigration patterns to the United States differ greatly. The focus of this entry is on native-born African Americans whose U.S. history dates back to the 17th century.

In the past, African-American families were presented as a homogeneous group. Current scholars, however, have cautioned that these families are diverse and complex and that there is no one type of African-American family. African-American families, much like other American families, are diverse in educational attainment, income levels, job status, family configurations (single parent, two parent, grandparent, multigenerational), geographic residence (urban, suburban, rural), and political views. Regardless of educational, social, and economic achievements, African-American families have minority status in the United States. This minority status has been associated with segregation and discrimination often resulting in African-American families facing extraordinary social and economic challenges (e.g., housing and employment discrimination).

African Americans, however, share unique qualities and strengths (e.g., family loyalty, racial pride). These qualities and strengths are not exclusive to African-American families, but they have been critical for successful adaptation and resiliency—including the ability to recover from setbacks—in the face of social and economic challenges. This entry will discuss a few of these strengths found among many African-American families that lead to positive outcomes for African Americans, such as a sense of family stability, effective coping strategies, and successful outcomes for children (e.g., high self-esteem).

Extended Family Support Networks

As with other American families, the family configuration of the majority of African-American families is the nuclear model of parent or parents and children. However, extended family living patterns are common among African-American families (e.g., grandmother, mother, and child living together in the same household). One reason for the extended household is economic necessity. Divorced or single parents, widows, and the elderly often find themselves faced with financial challenges due to lower income status. Moving in with family members helps to relieve some of the financial burden by sharing expenses.

Other reasons for extended households are family obligation and family devoutness. These are expectations of helping family members who may need assistance and feeling a sense of family loyalty to help take care of members, particularly caring for older family members who may have participated in caring for the younger generations. Cultural norms in the African-American community support and sanction these types of diverse family configurations.

Extended family households also have reciprocal psychological, social, and economic benefits between family members. Psychologically, the intergenerational relationships provide family members with a sense of belonging, attachment, and protection. Socially, diverse family configurations also permit members to share and exchange role responsibilities, such as providing childcare for working parents or elder care for the older adults in the household. The adaptability and flexibility of roles also provide households members with financial, emotional, and practical support such as food, clothing, information, and advice. These types of support allow parents to pursue and maintain employment and to avoid expensive childcare cost and allow younger members to attain higher educational status. It is also helpful that African-American men and women deemphasize strict gender roles and are more willing to share household tasks and responsibilities as needed. Older family members also provide emotional and financial support, serve as confidants, and provide childcare. They often possess valuable knowledge, skills, and insight to share with the younger generations. This exchanging and sharing of roles and

responsibilities is important for sustaining family closeness and for improving self-esteem and self-confidence of members. In all, extended families provide African-American families a functional, mutually beneficial network from which to give and receive care, shelter, support, and protection.

Strong Work Ethic

A strong work ethic is another identified strength that is present among many African-American families. Historically, the types of jobs that were available to African Americans have often been low-skilled, low-paying, transient positions (e.g., laborers, domestic workers). Yet even in the face of structural disadvantages such as discrimination and unequal access to the labor market, African Americans have long histories of labor force participation.

Unfortunately, on average, African Americans earn only 65 percent of what other Americans earn with similar education and employment positions. Further, when African Americans start at the same income levels in the same jobs, their rate of promotion and pay raises are lower than other employees. Despite labor discrimination at many levels, African-American families are found in low-income, middle-income, and high-income social classes.

This strong work ethic is found in both African-American men and women. Current labor force trends show that more women of all ethnicities are entering the workforce. Regardless of marital status, African-American mothers have the highest labor force participation of mothers of any other racial or ethnic group. In fact, historically, African-American women's employment has been vital to the economic survival of the African-American family. Too often, African-American men have been portrayed as inadequate providers, but studies show that when discriminatory obstacles and barriers are removed and they are allowed fair access to traditional economic opportunities and resources such as education and jobs, then African-American men are able to successfully fulfill the provider role for their families. Contrary to popular perceptions portrayed in the media, the majority of African-American parents are hard-working individuals taking care of the economic, health, and material needs of their children.

Racial Socialization

Racial socialization is another strength found among African-American families. Socialization is when children are taught to become independent, competent adults and to understand the norms and values of their larger society. This is an important task for all parents. Racial socialization, however, is a distinct strategy for African-American parents because it prepares African-American children for a society that devalues their racial minority status. The racial socialization process can include communication about racial pride that emphasizes the importance of African-American history and accomplishments. The socialization messages also can focus on the challenges associated with racial discrimination and prejudice. Racial socialization serves to enhance children's sense of group identity (e.g., a "we" mentality) and helps develop self-esteem and self-pride in themselves and in their culture.

Racial socialization can be rewarding because a positive group identity helps protect children from the harmful psychological consequences of discrimination, insults, negative messages, and attitudes about their race. For example, children who have not had at least some racial socialization might internalize and believe any negative media images or messages they encounter about their race and suffer psychological distress and/or low self-esteem. Children whose parents practice racial socialization usually achieve high academic status and display proficient social skills. Socializing children to African-American history and culture in addition to mainstream American culture provides children with the adaptive strategies necessary to successfully participate in both dominant and minority communities.

AGE AT FIRST MARRIAGE

Social scientists view marriage as a social institution that is influenced by cultural and economic factors. The influence of societal changes on the institution of marriage is illustrated by the variations in age at first marriage in the United States over the course of the 20th century. According to U.S. Census Bureau data, in 1900 the median age at first marriage was 21.6 years for women and 25.9 years for men. Age at first marriage declined through the first part of the 20th century until reaching the youngest ages in 1950s. In 1950, the median age at first marriage was 20.3 for women and 22.8 for men. The 1950s was characterized by unprecedented economic growth; by the mid-1950s, the percentage of the population that had a middle-class income level almost doubled compared to the 1920s. Such economic prosperity meant that people married and had children at earlier ages. Compared to earlier decades, more people married, had more children, and were less likely to divorce.

These changes in marriage were relatively short-lived. Since the 1950s, age at marriage for both women and men has steadily increased; in 2003, only 50 percent of women were married by the age of 25, and 50 percent of men married by the age of 27. Results from a recent General Social Survey indicate that most people believe that marriage should occur after completion of education, obtaining a full-time job, and reaching financial independence. In general, people indicate that 25 years old is the right time to marry, while those who are college educated assert that 27 is the ideal age.

The increasing age at first marriage in the United States is also consistent with changes in other countries. Young adults marry at later ages in more industrialized and urban societies compared to less industrialized and more rural societies, although age at first marriage is also increasing in less industrialized and more rural areas of the world. The average age at first marriage in Japan is 28 years for women. In contrast, many women in sub-Saharan Africa marry before the age of 20. Also consistent across cultures, men marry at older ages than women and are commonly several years older than their wives. Although gender roles are changing in the United States and other industrialized nations, men are still expected to demonstrate that they are able to support a family before they marry. These social norms are likely to contribute to the older age at first marriage for men. Additionally, some researchers speculate that men prefer young brides because younger women are more fertile.

A significant portion of couples in the United States are homogeneous with respect to age; in other words, couples are comprised of partners similar in age. According to 2000 Census Bureau data, 31.8 percent of married couples had an age difference of 1 year or less. Couples involving a slightly older husband are more common than couples comprised of an older wife. In 2000, 12.3 percent of married women were 2 or more years older than their husbands; in contrast, 36.3 percent of married couples in 2000 were comprised of a husband 2 to 5 years older than the wife. This pattern is even more pronounced when looking at larger disparities of the age of marital partners. In 2000, 19.6 percent of couples were comprised of a husband 6 or more years older than the wife, while only 3.3 percent of married couples were comprised of a woman 6 or more years older than the husband. Women in their second marriages are more likely to have an older husband than women in their first marriage.

The different settings people meet their potential spouses can affect age differences in marital partners. When people find their mates while in school, they are more likely to be close in age. Alternatively, when people marry a coworker or someone they met through their job, there is greater potential for the spouse to be significantly older or younger.

Societal and Economic Factors Associated With the Delay in Marriage

Several societal and economic changes are associated with the increasing likelihood that people will delay getting married. One of the most obvious changes is increased education. Marriage has traditionally been viewed as an adult rite of passage. Since marriage is relatively long-term and married couples are expected to set up their own households and not live with parents, being married while going to school is difficult. As more people are going to school for longer periods, people are delaying marriage. In particular, women are more likely to go to college now than in the past. A second societal change associated with the increased age at marriage is women's workforce participation. Women (and particularly married women) are more likely to be employed than in the past. Wives' employment is no longer viewed as a way for families to afford luxuries such as vacations but as an economic necessity. Furthermore, higher divorce rates increase the likelihood that many women will be supporting themselves and their children. Thus, women are increasingly likely to postpone marriage in order to establish their careers first. Additionally, changing gender roles mean that many couples no longer follow traditional patterns of husbands as the family providers while wives carry the primary responsibility for managing the home and family. Women with higher levels of education are actually more likely to marry in comparison to women with less educational attainment; studies indicate that men increasingly prefer women who have the same educational attainment as themselves or who have more education.

Two other societal factors related to later age at marriage are increasing rates of premarital sex and cohabitation. Recent studies indicate that the majority of adolescents engage in sexual intercourse before the age of 20. As sex before marriage is increasingly accepted, particularly in the context of a committed relationship, individuals are postponing marriage. Additionally, less restrictive attitudes toward nonmarital sex and cohabitation are associated with a greater likelihood that young adults will live with someone before marriage; roughly one half of young adults will cohabit before getting married. Young adults are cohabiting at around the

same age as people tended to marry in previous decades; for many people, cohabitation rather than marriage before age 24 is common.

Individual Factors Associated With Age at First Marriage

In addition to the societal and economic changes associated with the later timing of marriage, several individual characteristics are related to timing of marriage. People who are very religious are more likely to marry at earlier ages, in part, because they are more likely to hold strong pro-family values. Individuals with higher levels of education and income marry at older ages in order to establish their careers first. An increasing portion of people with lower levels of income and education are forgoing marriage completely. Research indicates that although people with less education and income are just as likely to desire marriage as those who are more affluent, they do not believe they have the resources necessary to marry. Individuals who live in the South and in rural areas tend to marry at early ages because they are more likely to hold profamily values. Family background is also related to age at marriage. People who grew up in intact biological or adoptive parent families are more likely to marry at earlier ages compared to those parents divorced, separated, or who were never married. The reason for this difference is also because of attitudes toward marriage; individuals whose parents did not marry or did not remain married have less favorable attitudes toward marriage.

Race and ethnicity are also related to the timing of marriage. Hispanics marry at earlier ages and are more likely to marry compared to Whites. One reason Hispanics marry at earlier ages is the culture of familism, which supports the creation and maintenance of family ties; studies indicate that Hispanics place a higher value on marriage compared to non-Latino Whites. Foreign-born Hispanics are more likely to marry and marry at earlier ages compared to Hispanics who were born in the United States. In contrast, African Americans tend to marry at older ages and are less likely to marry compared to Whites. Again, researchers speculate that much of the difference is due to African Americans' more favorable attitudes toward alternative family forms.

Age at Marriage and Risk of Divorce

The association between age at marriage and risk of divorce has been consistently documented in the literature on close relationships and marriage. People who marry in their teens are twice as likely to end their marriages compared to those who married after the age of 22. Some people speculate that the link between marrying at a young age and divorce may be due to lower levels of education and/or premarital pregnancy. However, even when researchers take these factors into account, the link between age at marriage and divorce persists. Scholars have cited two main reasons for this relationship. The first reason is poor role performance; those who marry young may not have the maturity and/or relationship skills to fulfill the role of a marriage partner. People who marry at young ages may find that their spouses and marriages do not meet their expectations. One study found that individuals who married before the age of 20 were more likely to report that their spouse was not faithful, tended to be domineering, and refused to talk about problems. People who married early were also more likely to indicate that jealousy was a problem in their marriage.

The second factor that might account for the link between early age at marriage and risk of divorce is the availability of alternative partners. Scholars report that both wives and husbands are more likely to divorce when alternative partners are readily available. Since people are more likely to divorce during the first few years of marriage, people who marry at young ages still have ample opportunity to find another marriage partner. Research on the timing of divorce indicates that couples who end a longer marriage (15 years or more) are significantly more dissatisfied with their relationship compared to couples who divorce in the first 7 years of marriage. This indicates that people in their first few years of marriage and who marry young may be less tolerant of problems with their relationships or partners.

Summary

The societal and economic factors related to the increasing age at marriage are not likely to change in the near future. College attendance and women's

workforce participation are likely to stay at current rates. Additionally, people may be more accepting of premarital sex and unmarried cohabitation in the future. Thus, the age at first marriage is likely to remain at current levels or to increase. One possibility is that marriage may no longer be considered necessary for maintaining a long-term relationship or for starting a family. Demographers note that societal acceptance of cohabitation occurs in stages. At the first stage, cohabitation is uncommon; in the second stage, it is viewed as preparation for marriage; in the third stage, it is an acceptable alternative to marriage; in the fourth stage, cohabitation is indistinguishable from marriage. The United States is transitioning from the second to the third stage. Sweden is currently in the fourth stage. The majority of first births in Sweden occur to couples who are not married and are cohabitating. Regardless of whether the United States follows the path of Sweden, age at first marriage is not likely to decrease any time soon.

AGGRESSIVE COMMUNICATION

Conflict is inevitable in human relationships. Whether conflict results in anger, hurt feelings, or satisfaction largely depends on the way individuals communicate. Understanding the role that aggressive communication traits and predispositions play

in conflict can provide valuable insight into communication behaviors people exhibit when disagreement exists. Predispositions toward aggressive communication have been found to explain much of a person's message-sending and message-receiving behavior. Aggressive communication involves one person applying verbal force to another, typically with a high level of arousal. Individuals engaged in aggressive communication often adopt "attack" and "defend" modes of thinking and behavior. These behaviors are essential for successfully resolving a conflict, though they can be employed destructively as well as constructively. This entry defines aggressive communication, distinguishes constructive from destructive symbolic aggressive communication, describes four aggressive communication traits, and explores consequences of constructive and destructive aggressive communication in relationships.

Symbolic Aggressive Communication

The first distinction made in categorizing aggression is physical versus symbolic. Aggression can take both physical and symbolic forms. Physical aggression involves the aggressor's forceful use of his or her body (roughly handling or striking objects or others). Symbolic aggression involves the aggressor's forceful use of his or her communication (words, gestures, facial expressions, vocal tone, etc.). It is this latter set of behaviors with which aggressive communication is concerned.

Symbolic aggression can be divided into two types: constructive and destructive. Aggressive communication is composed of not one but several traits including assertiveness, argumentativeness, hostility, and verbal aggressiveness. Each of these traits interact with environmental factors to produce message behavior.

Constructive Aggressive Communication

Assertiveness is considered a constructive trait because it involves verbal and nonverbal symbols to exert control, obtain justified rewards, and to stand up for one's rights. Individuals who are assertive use symbols aggressively, but they do so in socially acceptable ways. One facet of assertiveness is *argumentativeness*, defined as a stable trait

that predisposes individuals involved in a conflict to defend positions on controversial issues and to verbally attack the positions of others. Argumentativeness is considered a subset of assertiveness as all arguing is assertive communication, but not all assertiveness involves arguing.

Individuals differ in their level of trait argumentativeness and can be classified into three groups: high, low, and moderate. A person high in argumentativeness enjoys arguing and will eagerly and readily use arguments to attack others' positions and defend their own positions on issues. Highly argumentative individuals view arguing as an intellectual challenge and as an exciting competitive situation that allows them to display to others how communicatively skillful they are. Highly argumentative individuals also hold positive beliefs about arguing.

People low in argumentativeness feel uncomfortable about arguing before, during, and after the event that calls for argument. They lack the motivation, desire, and skill to argue across most situations and generally avoid talking about controversial issues because it makes them uncomfortable. Those low in argumentativeness hold negative beliefs about arguing. Individuals can also be moderate in argumentativeness. There are three types of moderate argumentative individuals: Conflicted-feelings moderates are highly emotional when it comes to arguing; they feel compelled to argue because of their level of competitiveness, yet they are also highly anxious about arguing because of their fear of failure. Apathetic moderate argumentatives are low in emotion when it comes to arguing, yet they feel little to no anxiety about engaging in an argument. Neutral moderate argumentatives will argue only when they see some good coming out of it and feel that they have a good chance of winning.

Destructive Aggressive Communication

There are two destructive forms of symbolic aggressive communication: hostility and verbal aggressiveness. Hostility is exhibited in interpersonal communication when people use messages to express irritability, negativity, resentment, and suspicion. Irritable communicators have quick tempers, show little patience, are moody, and

appear exasperated when things go wrong for them. Negative communicators express a great deal of pessimism, display little cooperative effort, and are often antagonistic toward authority, rules, and social conventions. Resentment is expressed through jealousy and brooding about perceived slights, either real or imagined. Suspicion is communicated by distrust of others.

Verbal aggressiveness is defined as the tendency to attack the self-concept of individuals instead of or in addition to their positions on topics of communication. These attacks most commonly take the form of character attacks (e.g., "You're a liar and a cheater!"), competence attacks (e.g., "You can't do anything right," or "You're a lousy lover"), teasing, ridicule, profanity, maledictions (i.e., wishing someone harm, as when one says to someone "Drop dead"), background attacks, physical appearance attacks (e.g., "Your nose looks like a pig's nose"), threats, and nonverbal "verbal" behaviors (e.g., raising the middle finger in the "up yours" gesture, sticking out the tongue, rolling the eyes).

The essential difference between argumentativeness and verbal aggressiveness is in the locus of the attack. In argumentativeness the attack is on the adversary's position on the controversial issue; in verbal aggressiveness, the attack is on the adversary's self-concept. For example, one spouse suggests vacationing in Florida in February. The other disagrees, stating, "The weather is too cold and variable in Florida during February." This constitutes an example of an argumentative response. Stating, "You're so stupid for wanting to go to Florida in February—the weather sucks!" would constitute a verbally aggressive response and one that is potentially destructive to the relationship. Verbally aggressive behavior is more common in exchanges where the consequences are very meaningful to those involved.

Causes of Verbal Aggressiveness

Several reasons have been offered for the development of the verbal aggressiveness trait: psychopathology (repressed hostility or neuroticism), disdain for the other person, social learning of aggression, and argumentative skill deficiency (i.e., not possessing the skill and ability to generate constructive

arguments during a conflict). Communication scholars have suggested a fifth cause of verbal aggressiveness: the inherited trait explanation. This explanation suggests that verbal aggressiveness is an expression of temperament. That is, people are born with a set of biologically determined temperaments that are relatively consistent throughout their lives of which verbal aggressiveness is one.

An important study found that individuals high in verbal aggressiveness view competence attacks, character attacks, maledictions, nonverbal emblems (i.e., gestures that take the place of words), ridicule, and threats as less hurtful than those who are low in verbal aggressiveness. Individuals high in verbal aggressiveness reported several reasons for being verbally aggressive: trying to appear tough, experiencing rational discussions that degenerate into verbal fights, wanting to be mean to the other person, and wanting to express disdain for the other. In another study, it was observed that highly verbally aggressive individuals often perceive that their verbal aggression is justified.

Measurement of Aggressive Communication

Like other communication and personality traits, argumentativeness and verbal aggressiveness are measured with paper-and-pencil self-report questionnaire instruments. Scores on the Argumentativeness and the Verbal Aggressiveness Scales help individuals understand how they compare with the norms established for each scale.

The Argumentativeness Scale measures trait argumentativeness, the predisposition to engage in argument that is embedded in personality. In conflict situations, individuals respond based on competing approach and avoidance motivations for engaging in argument. These motivations are based on both personality (trait) and situational (state) factors. Based on this assumption of coexisting motivations to engage in argument, approach and avoidance subscales were designed to measure both dimensions. Thus, general trait argumentativeness (ARGgt) equals the predisposition to approach argument (ARGap) minus the predisposition to avoid argument (ARGav), or $ARGgt = ARGap - ARGav$. Examples of items that measure ARGap include "I am energetic and enthusiastic when I argue," "I enjoy a good argument

over a controversial issue," and "I enjoy defending my point of view on an issue." Examples of items that measure ARGav include "Arguing with a person creates more problems for me than it solves," "I get an unpleasant feeling when I realize I am about to get into an argument," and "I am happy when I keep an argument from happening." Scores on the scale have been found to predict, for example, the desire to debate a controversial issue with a colleague, the amount of argumentative behavior exhibited in a group problem-solving task, and the degree of disappointment when an anticipated argument does not take place.

The Verbal Aggressiveness Scale was developed to measure the predisposition in which individuals attack the self-concept of another instead of or in addition to their positions on controversial issues. The scale assumes the existence of verbal aggressiveness, so some items ask where, how, and when it is expressed rather than whether it is expressed (e.g., "When individuals insult me, I get a lot of pleasure out of really telling them off"). Second, in some items, justification for the behavior is provided to legitimize the expression of verbal aggressiveness (e.g., "When people refuse to do a task I know is important, without good reason, I tell them they are unreasonable"). Finally, in some items, the verbally aggressive response is made to appear benevolent (e.g., "I try to make people feel good about themselves even when their ideas are stupid"). These strategies are consistent with research revealing that aggressive individuals often attempt to self-justify their socially undesirable aggressive behavior. Verbal aggressiveness scores allow us to predict, for example, the likelihood that a person will use verbal aggression to secure compliance in social influence situations (e.g., "I would tell my friend that he [or she] is simple-minded for not agreeing to vote in favor of my position on this issue") and the amount of teasing a person will engage in with their siblings.

Consequences of Constructive and Destructive Aggressive Communication

The most fundamental conclusion that has been reached by the vast amount of research conducted on aggressive communication over the last quarter of a century is that most outcomes of argumentativeness

are constructive, while most outcomes of verbal aggressiveness are destructive. Several benefits have been associated with argumentativeness. First, argumentativeness enhances perceived credibility. Argumentativeness has been related to credibility because of the assumption that higher levels of the trait may indicate more skill in arguing and reasoning. Research has revealed that more skillful advocacy, refutation, and rebuttal behavior suggests greater competence in communication. High argumentatives are more likely than low argumentatives to be seen as leaders in groups. Argumentativeness has also been associated with higher levels of self-esteem, especially perceptions of personal power and competence.

Recall that a skill deficiency in argument has been suggested as one explanation for verbal aggressiveness. That is, when individuals are low in motivation to argue and lack the skill to generate arguments during conflict, these deficiencies can lead to verbal attacks being directed to another person's self-concept instead of his or her position on controversial issues. Verbal aggression has been suggested as a catalyst for physical aggression. Thus, being high in motivation and skill in argument may reduce the likelihood that this cycle will result because skilled and motivated arguers are better able to direct a verbal attack toward their adversary's position and not toward his or her self-concept.

AGING PROCESSES AND RELATIONSHIPS

More adults are living to advanced old age than ever before. In 1900, the average life expectancy was approximately 47 years, and only about 3 million U.S. citizens were 65 years of age or older. As of the 2000 U.S. Census, average life expectancy is about 77 years, depending on gender and race, and at least 35 million persons are 65 or older. The number of centenarians, those 100 years of age or older, increased from about 37,000 in 1990 to over 50,000 a decade later. What do these trends mean for family and friend relationships? On the one hand, older adults are experiencing family and friend relationships for longer than ever. On the other, younger people have increasing opportunities to know and interact with multiple generations of middle-aged and older adults. This entry addresses the effects of aging-related physical and psychological changes on close relationships, including both promising and problematic implications of aging for social interactions.

Age-Related Physical and Psychological Changes

The life-span development perspective as articulated by Paul Baltes encompasses the key idea that

development is a lifelong process extending beyond the years of childhood and adolescence throughout the years of adulthood and old age. Development entails both growth or gains and decline or losses across the entire span of life. According to this view, the rate and direction of change vary for different aspects of human life, such as physical, cognitive, or personality functioning. Development is affected by historical, cultural, and social contexts, and developmental processes are modifiable through individual and societal interventions. Changes that take place in physical, social, emotional, cognitive, and other domains set the stage for experiences in family and friend relationships. Reciprocally, interactions with other people can have an impact on a person's development.

Under ordinary circumstances, peak physical functioning takes place during the adolescent and young adulthood years. As individuals grow older, they may begin to notice some external signs of aging, such as increased skin wrinkling and decreased visual acuity. Note, however, that most organ systems function well into very old age. Many of the physical limitations attributed to aging actually result from lifestyle choices that interfere with good health, such as poor diet, inadequate exercise, or smoking. Adults who engage in health-promoting behaviors generally can function well despite advancing age. Even so, wear and tear on the body along with some genetically programmed changes mean that older adults are likely to experience gradual decline in vision and hearing, the circulatory system, bone density, and muscle mass. Brain structure and functioning also changes with age. If any of these conditions lead to serious changes in health and functioning, the ability to interact with family and friends can also become impaired.

Turning to the psychological domain, Erik Erikson offered an analysis of psychosocial development across the life span that highlights particular challenges or turning points with emergent strengths or failures for each stage. In the adult years, the challenges encompass developing the capacity to form intimate relationships and care deeply about others versus remaining isolated, becoming concerned about the welfare of future generations versus being self-absorbed, and accepting one's life as satisfying and meaningful versus

regretting one's choices and fearing death. Resolving these challenges successfully contributes both to personal maturity and to the quality of social relationships.

Although different stages of life bring different challenges to the foreground of experience, basic personality traits, or typical patterns of thoughts, feelings, and actions, tend to remain constant across the adult years. Robert McCrae and Paul Costa have confirmed the stability of the Big Five personality traits (neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness) throughout the adult years in many cultures. This means that ways of responding to life events and social interactions are not likely to change much with the passage of time. Similarly, many adults retain good cognitive functioning well into old age, especially if they are healthy and well educated. Even very old adults can learn new information, master new technology, and acquire new interests—it just might take them longer than when they were younger. Individuals who exhibit severe memory loss or sudden personality change are likely to be experiencing the effects of disease processes, not normal aging.

Impact of Aging on Close Relationships

Most older adults have close relationships with numerous family members and friends. Their social interactions reflect both continuity—sibling, parent–child, and friend ties are very long-lasting—and change wrought by relocating from one community to another or by the increasing functional limitations of older adults as well as the functional limitations or death of their relatives or friends. Growing old can have both positive and negative effects on the quality of close relationships, reflecting the lifelong complex interplay between personal development and social bonds.

Positive Effects of Aging on Relationships

Same-Generation Relationships

The relational benefits of living for a long time are manifold. Considering first the personal relationships older adults have with their age peers, research shows that long-standing experience can

be advantageous for marriage, sibling ties, and friendships alike. Most individuals who stay married into their later years as well as those who choose new romantic partners in late life rate their marital or marital-like relationships as happy and satisfying. This is partly because unhappy marriages or partnerships are likely to have ended in divorce previously. Also, stable personality traits contribute to stable patterns of marital interaction. In addition, older partners typically have learned to manage the give-and-take of intimate life, have had practice in resolving difficulties, and take pleasure in being close with someone they care about deeply.

Although some adults find themselves too busy to interact much with their sisters and brothers during the busy years of rearing children and pursuing work goals, especially when siblings live far apart, relationships with siblings may take on new meaning in old age as work and family responsibilities decline. Sibling ties are the longest-lasting family bond, and studies show that siblings usually keep in touch throughout life or at least are aware of one another through common contact with other persons. In old age, renewal of sibling bonds can provide pleasurable opportunities to reminisce about a shared past as well as a sense of security and reassurance in the face of uncertainty about future health care and other needs.

Adults who nurture long-term friendships and make new friends throughout life can reap the beneficial effects of knowing significant others deeply and enduringly. The majority of older adults have friends, interact with them often, and appreciate the companionship, understanding, and support that friends provide. In fact, research shows that friends contribute to older adults' life satisfaction more than family members do, probably because friendship ties are based more on choice than obligation. Many older adults make sure they stay in touch with long-term friends as well as enjoy the stimulation that a widening circle of new friends can bring.

Intergenerational Relationships

Looking at the intergenerational family relationships of society's elders reveals other positive dimensions of old age. With increased longevity comes the potential for knowing multiple succeeding generations of kin, a benefit which was not possible in the past when people lived barely long

enough to see their children become adults. Generally, parent-child relationships are more peer-like than hierarchical at this stage of life. Older adults rely on their children for companionship, emotional support, and instrumental help; in turn, offspring usually report commitment to filial responsibility for aiding their aging parents. Having grandchildren and great- or even great-great-grandchildren provides elders with a strong sense of family lineage continuity and numerous opportunities for expressing generativity to their heirs. Many elders obtain great satisfaction from associating with their grandchildren, particularly in the absence of extensive responsibility for rearing them. Based on accumulated life experience, older adults can impart wisdom, transmit social and other skills through role modeling, and convey forgiveness for transgressions within the family. Often older adults serve as the kinkeepers who foster cross-generation linkages, promote extended family ties, pass on ancestral lore, and preserve family legacies and traditions.

The gain-loss phenomenon described previously can be applied to late-life close relationship changes. For example, among older adults who can afford to retire from paid employment, the availability of more discretionary time contributes to the likelihood of pursuing the preferred amount of family interaction as well as having more time for friends and mutually enjoyable activities with them. In this sense, retirement represents a social gain even while it entails loss of work-based contacts and activities. Moreover, older adults usually perceive themselves as having more freedom than in the past to choose the relationships and relational foci they wish to pursue while letting less meaningful ties fade away.

Negative Effects of Aging on Relationships

Along with the strengths old people might bring to family and friend relationships, advanced levels of age-related changes in physical or psychological function can create relationship impediments that frustrate older adults and their significant others. If older adults have living parents, the parents are likely to be quite frail and in need of support, but the older adult offspring may require assistance as well. In such cases, older adults who are already supporting their spouses as well as adult

grandchildren who are tapped for assistance can feel overwhelmed from having multiple generations of family elders to support along with all the other demands on their time. Normative slight declines in vision, hearing, and mobility usually are inconsequential to relationships. But more extensive hearing impairment can interfere with effective communication while high levels of vision or mobility loss can isolate older adults from their family and friends. If elders must cease driving but do not live near public transportation or are too frail to use it, their physical limitations can have direct impact on their relationships. Unresolved developmental challenges related to generativity, or concern for the welfare of future generations, and integrity, or satisfaction with life, can result in older adults who are self-absorbed and fearful of death.

Even more serious in some ways is the effect of memory loss on family and friend relationships. Older adults who become confused in their surroundings and cannot remember names of loved ones may be reluctant to socialize or pursue hobbies and interests with others. Brain damage associated with Alzheimer's disease and other forms of dementia can lead to unexpected and unpleasant personality changes that make it difficult to be around the affected elder. Such cognitive and memory declines demand great patience of relatives and friends, who must be willing to tolerate loss of the usual relational reciprocity found in close relationships.

Another negative dimension of old-age relationships is the potential for long-standing unresolved conflicts to be sustained over many years, leading to ongoing relational disharmony and disappointment or even abuse and violence. Often, the victims of mistreatment in old age are the very persons who engaged in relational violence when they were younger, reflecting a destructive cycle of abuse transmission over the generations.

Ageism, or negative stereotyping of old people and prejudice against them, is rampant in U.S. culture. Ageist attitudes and values can promote beliefs that old people have nothing to offer younger relatives or friends and can inhibit older adults from pursuing romantic relationships. Older adults themselves may believe ageist stereotypes and refrain from seeking new relationships or engaging in activities where they feel unwanted. Segregating older adults from the rest of society

not only reduces their chances for meaningful social interactions, it also prevents them from contributing to the social good.

A final consideration of the negative aspects of old-age relationships concerns bereavement. Older adults are more likely than persons in any other age group to experience death of parents, spouses, siblings, and friends. Some must cope with loss of children or grandchildren as well. Although bereavement is difficult at any age, the accumulation of deaths among family and friends can be especially troublesome for older adults who grieve repeatedly. In addition, loss of key relatives and friends can make old people feel particularly vulnerable as they face their own advanced years and the potential need for increased assistance and emotional support.

AGREEABLENESS

Agreeableness is one of the five major dimensions of personality within the five-factor structural approach to personality (also known as the Big Five). It is an abstract, summary term for a set of lower-level traits that describe individual differences in being likable, pleasant, and harmonious in interactions with others. Agreeableness has been conceptualized as a motivational system that is concerned with maintaining positive relationships with others. Of the major dimensions of personality in the Big Five, Agreeableness is the one implicated most in how individuals differ in their orientations towards interpersonal relationships. Because of this motivation, Agreeableness generally influences a wide range of thoughts, feelings, and social behaviors. There are many implications for social relationships if people differ in their motives to maintain positive relationships.

Friendships and romantic relationships have been conceptualized in terms of sequential phases. Relationships begin with an initiation phase, which includes attraction and dating. Once relationships have been initiated, they quickly move into the maintenance phase. If a couple's attempt at maintenance fails, relationships move into a series of phases involved in the dissolution of the relationship. These phases include decline, repair, and exit. Different behaviors and responses to a relationship partner are required at each phase, but agreeableness is related to all five phases of the relationship sequence. This entry describes recent research examining the relationship between agreeableness and relationship behavior at each of these five phases.

Relationship Sequence

Stage 1: Initiation

Initiation of a relationship generally occurs because individuals are attracted to each other. Once individuals realize this initial attraction, they may undergo a series of initiation behaviors, such as spending time together (friendships) and dating or sexual intercourse (romantic relationships) in an effort to establish the relationship.

Attraction

According to now classic research on attraction, one of the leading causes of attraction is similarity. Individuals are attracted to people who are similar, or who they believe are similar, to them. Recent research on helping behavior has provided initial evidence that individuals high in agreeableness rate victims in need of help as more similar to themselves and more likeable. They also treat outgroup members—people who come from different social groups than oneself—similarly to ingroup members—people from one's own social group—in most respects, such as in terms of helping or prejudice. If agreeableness is related to perceptions of similarity, then agreeableness and attraction may be related also. That is, individuals high in agreeableness may find more potential dating targets similar to themselves than do individuals low in agreeableness. This may lead individuals high in agreeableness to finding more others attractive, even when they are relatively dissimilar to themselves.

Recent research has shown that agreeableness is an important characteristic that women want in a potential dating partner. In an experimental study examining whether women are attracted to “nice guys,” women were asked to rate the attractiveness and desirability of men who behaved in prosocial, agreeable ways and of men who did not. Given the same level of physical attractiveness, men who behaved in a prosocial, agreeable way were rated as more attractive and more desirable as a dating and sexual partner. This research provides initial evidence that women look for prosocial motives in their mates, and agreeableness may be an important predictor of this attraction.

Initiation Behaviors

Once attraction between two people has been established, certain behaviors facilitate the

development of the relationship. Two of these behaviors are commitment and sexual intercourse. Extending the finding that agreeableness is related to attraction among women, recent research found that agreeableness was related to commitment and frequency of sexual intercourse. Men low in agreeableness report more casual, uncommitted relationships and a higher frequency of casual sex. Women also rated these low agreeable men as more desirable for uncommitted relationships, which included higher rates of casual sex. These results point to the idea that agreeableness is related negatively to commitment and positively to frequency of casual sex, especially in short-term relationship contexts.

If one examines the reasons underlying this negative relationship between agreeableness and frequency of casual sex, different patterns of motivation in men and women are uncovered. Overall, for both men and women, agreeableness was related to higher levels of commitment in relationships. Men high in agreeableness report having sex when they feel loving and committed to their partner. Among women high in agreeableness, however, patterns were less clear. For them, virtually every major reason for sex was negatively correlated with agreeableness. By comparison, in women virtually every major reason for sex was positively correlated with neuroticism, an individual's level of emotional stability. Part of the explanation may rest with the fact that women high in agreeableness report less casual and unrestricted sex. Another possibility is that women high in agreeableness are more traditionally romantic and prefer not to endorse any reason for having sex, as it is too personal.

Stage 2: Maintenance

Once the initiation stage of relationships is concluded, relationship maintenance behaviors become important. If relationships are not maintained, they may decline and possibly dissolve. Not surprisingly, agreeableness is related to many relationship maintenance behaviors. Inherent in the definition of agreeableness is the motivation to maintain positive relationships and therefore, the maintenance of personal relationships.

Satisfaction

Agreeableness is related to satisfaction in relationships. Research indicates that men who are higher in agreeableness are more satisfied with their relationship and rate their relationship as more intimate than men who are low in agreeableness. This is not true for women. Agreeableness seems not to be related to perceptions of relationship satisfaction or intimacy for women.

Recently, trait expressiveness has been linked to marital satisfaction. Trait expressiveness is not linked empirically to agreeableness, but there are reasons to believe that the two constructs are related. The words used to categorize people high in trait expressiveness—kindness and understanding—are similar to those used to describe individuals high in agreeableness—warm and kind. Trait expressiveness leads to greater levels of affectionate behavior in relationships, which in turn leads to greater responsiveness from a spouse. These higher levels of affectionate behavior and responsiveness lead to greater marital satisfaction in both husbands and wives. These processes could also hold true for agreeableness because of the similarities between trait expressiveness and agreeableness.

Perceptions of a partner's agreeable behavior have also been shown to be an important determinant of relationship satisfaction. When members of couples perceive their partner as more agreeable than would be expected (based on perceptions of the frequency of their partner's agreeable behaviors), they may begin to have positive illusions about their partner. That is, they see their partner as displaying more agreeable behavior than the partner actually displays. Spouses who have positive illusions of their partner rate themselves as being more in love as newlyweds and remain more in love throughout their marriage.

Social Support

Perceived social support is also related to perceived levels of agreeableness. Individuals who are perceived as more agreeable by their family members are also perceived as more supportive to their family members. This effect does not hold for mothers, however. Mothers are perceived as supportive regardless of how their family members perceive them as high or low in agreeableness. There is no evidence, however, that perceptions of

support are related to actual agreeableness. That is, individuals who perceive more support from their family members are not necessarily higher in agreeableness than individuals who perceive less support from their family members.

Conflict

Agreeableness is also related to observed negative interactions in marriages. Wives and husbands who are lower in agreeableness report and experience higher levels of negative interactions in their marriages. This is true when the spouse rates their partner's level of agreeableness as well. That is, a wife who perceives her husband as higher in agreeableness also reports lower levels of negative interaction in their marriage and vice versa. Self-ratings of agreeableness are also positively related to sexual satisfaction and perceptions of marital quality for both husbands and wives. Spouses who are higher in agreeableness are more sexually satisfied in their marriage and have more positive global evaluations of their marriage.

Agreeableness is related to the type of response an individual uses in these negative interactions as well. Individuals high in agreeableness are more likely to respond to conflict in constructive ways, such as negotiation, whereas individuals low in agreeableness are more likely to use negative tactics of asserting power of their partner (e.g., yelling and hitting).

Individuals high in agreeableness are also more likely to display accommodation behaviors in romantic relationships. Accommodating behaviors occur when an individual responds to a partner's negative behaviors in a relationship-enhancing manner. Individuals high in agreeableness are more likely to use accommodating behaviors in relationships than their peers. In fact, being accommodating to romantic partners may be an automatic response (i.e., a response that requires no cognitive effort) to negative behaviors in individuals high in agreeableness.

Stage 3: Decline

One reason relationships begin to decline, the third phase, is because the relationship is not properly maintained by either member of the couple. Little research to date has examined the link between agreeableness and relationship decline.

Based on the positive relationship between agreeableness and relationship maintenance behaviors, researchers might expect that agreeableness is negatively related to decline in relationships. If individuals high in agreeableness are more likely to display accommodating behaviors and respond to conflict in a more positive manner, they should be less likely to experience decline in their personal and romantic relationships.

Relationship decline is associated with decreases in levels of commitment and decreases in the number of investments partners share. Based on the relationship between agreeableness and commitment, it is reasonable to expect that agreeableness may exhibit a similar pattern when predicting relationship decline. More specifically, because higher levels of agreeableness are related to higher levels of commitment, and therefore higher levels of investments, agreeableness should also be positively related to lower levels of relationship decline.

Stage 4: Repair

Once relationships begin to decline, repair behaviors are necessary, or the relationship will either end or remain dissatisfying. One important factor in relationship repair is forgiveness. One or both couple members must forgive each other for repair to occur fully. Research examining the relations among agreeableness and forgiveness has identified a positive relationship between them. That is, individuals high in agreeableness are more likely to forgive others, thereby possibly leading to higher rates of repair in relationships.

Empathy and perspective taking may be additional factors involved in successful relationship repair. To reverse the decline of a relationship, couple members must recognize the perspective of their partner. Being able to take the partner's perspective and, therefore, feel empathic concern for the partner should lead to prosocial behaviors and more successful attempts at repairing relationships.

Stage 5: Exit

If repair attempts are unsuccessful, the final relationship phase, exit, is reached. The term *exit* is used traditionally to describe the end of a relationship, but it has also been used to denote one

response to conflict (i.e., avoiding or ending the conflict—threatening to leave the relationship or walking out to end conflict; voice—actively working constructively with the partner to improve the situation, loyalty—saying and doing nothing but optimistically waiting for improvement, and neglect—avoiding discussion of critical issues are additional strategies). Little research has examined the link between agreeableness and exiting or ending relationships, but research on agreeableness and conflict resolution strategies may shed light on this topic. Similar to research on conflict resolution, agreeableness should be related to more positive endings of relationships. Because agreeableness is defined as the motivation to maintain positive relationships with others, agreeableness may be related not only to the positive behaviors in the dissolution of relationships but also to more positive behaviors following the dissolution of the relationship.

AIDS, EFFECTS ON RELATIONSHIPS

Human immunodeficiency virus (HIV) destroys the blood cells critical to healthy immune functioning and compromises the body's ability to fight off illnesses. HIV infection occurs through sexual or blood-to-blood contact, and the primary

transmission vector, unprotected sex, typically occurs in the context of dyadic relationships. Once infected, people living with HIV disease become susceptible to opportunistic infections, may develop AIDS, and can die. People living with HIV/AIDS (PLWHA) experience their illness in the context of relationships with sexual partners, social support providers, medical professionals, caregivers, and long-term relationship partners. Some key issues in considering AIDS and relationships include prevention of HIV transmission, social support and caregiving, and potential loss and bereavement.

HIV Prevention and Safer Sex

In order to minimize the risk of HIV infection and other sexually transmitted diseases, couples should use a latex condom during oral, anal, or vaginal sexual contact. Studies of diverse populations from around the world indicate that people in long-term and committed relationships, both heterosexual and homosexual, use condoms less frequently than more casual couples. This could be because married or cohabiting people generally do not perceive that they are at risk for HIV infection. Couples also may engage in unprotected sex because they view condoms as detrimental to their relationship or as implying that partners are not monogamous or cannot be trusted. Research suggests that relationship dynamics and qualities are important in safer sexual practices. Specifically, feeling intimate with a partner predicts sexual behavior; greater intimacy, closeness, and commitment all predict reduced likelihood of using condoms.

Interestingly, marriage is actually a risk factor for HIV infection, particularly for women. Research with heterosexual couples suggests that married couples use condoms less frequently than unmarried couples and especially to the extent that they perceive little HIV risk from partners. Moreover, in many cultures around the world, gender expectations and social norms do little to discourage infidelity in husbands and simultaneously make it more difficult for wives to demand safer sexual practices. Such cultural norms heighten the risk of HIV infection for both partners.

In some couples, one partner is HIV positive (HIV+) and one is HIV negative (HIV–, i.e., they

are serodiscordant). In these couples, secondary prevention, or how to simultaneously prevent HIV transmission to the uninfected partner and minimize health risks to the HIV+ partner, is a central concern. Research suggests that couple serostatus is related to sexual behavior and intimate relating; unprotected sex is more likely in couples in which *both* partners are HIV+ (i.e., they are seroconcordant) than in couples in which only one partner is HIV+ (serodiscordant). Although PLWHA may be motivated to practice safer sex to protect their HIV- partners, relationship closeness seems to influence the likelihood that couples engage in unprotected sex. Even among serodiscordant couples, greater feelings of relationship closeness predict greater likelihood of engaging in unprotected sex, with this tendency more pronounced among women than men in heterosexual relationships. The more dependent or less powerful partner in a relationship (e.g., women in traditional heterosexual relationships) may be pressured to not use condoms or it may be impossible for them to insist on safer sexual practices even when they are motivated to do so.

Couple-based interventions may be one way to minimize HIV risk in couples of all types. When both couple members support and encourage condom use, risky sexual behavior occurs less frequently. And to the extent that safer sexual practices can be linked to maintaining a satisfying and caring relationship, couples may be less likely to engage in unsafe behaviors.

Social Support and Caregiving

Social support is critical for the health and well-being of PLWHA. Support from partners, families, and friends is associated with less substance abuse and distress (e.g., hostility, depression, anxiety, and grief) and increased health promotion behaviors among PLWHA. Social support also has the potential to impact dyadic functioning; it can organize couple behavior patterns and interactions and may serve as one means of relationship maintenance for couples coping with HIV/AIDS.

Although PLWHA may receive support from people who do not know their serostatus, those who disclose that they are HIV+ typically report

greater social support after doing so. A related research finding is that, among gay identified HIV+ men, social inhibition and being “in the closet” about their sexual identity are both related to poorer overall health and faster disease progression. Thus, concealing disease status (or sexual identity for some PLWHA) may prevent HIV+ individuals from benefiting from social support that could be provided by others.

Although social support is generally associated with positive outcomes for PLWHA, it appears that support provided by informal caregivers, rather than family members, friends, or professionals, especially predicts improved health and well-being. One potentially important determinant of this effect is relationship quality. Research suggests that greater relationship quality between caregiver and PLWHA is associated with fewer symptoms and better overall health for the HIV+ partner.

In providing support and assistance, caregivers face difficulties of their own. They may witness health and psychological changes in the HIV+ partner, and they experience stress in redefining their relationship and engaging in caregiving activities. Caregivers may find it difficult to fully commit to their partners, their new roles, and to caregiving, and these challenges seem particularly difficult for caregivers who are themselves HIV+. In fact, HIV+ caregivers report greater feelings of burden than HIV- caregivers. Nonetheless, it is important to note that caregivers also often report increased relationship closeness as a result of caregiving.

The challenges of caregiving may be complicated by stigma associated with HIV disease and by the caregiver's serostatus. Caregivers may fear or experience *courtesy stigma*, negative feelings and prejudice from others associated with HIV disease, with this stigma contributing to their feelings of isolation, burden, and depression. If the caregiver is HIV+, these negative effects may be especially pronounced; HIV+ caregivers report greater feelings of stigma than their HIV- counterparts, especially if their own health is compromised. Feelings of stigma among caregivers also are associated with greater feelings of depression, anxiety, and hostility. In short, caring for a PLWHA is stressful and can be particularly difficult for HIV+ caregivers.

Potential Loss and Bereavement

With medical advances, the course of HIV/AIDS in industrialized countries has changed dramatically, and PLWHA can remain healthy and live longer than earlier in the epidemic. However, a climate of loss still permeates communities hardest hit by HIV/AIDS (e.g., the gay community in the United States). Members of these communities have experienced the deaths of numerous friends and loved ones, with these multiple bereavements producing "AIDS fatigue" and psychological distress even among uninfected individuals.

PLWHA and their relationship partners commonly experience anticipatory mourning, a process of dealing with imminent or anticipated death. Anticipatory mourning enables PLWHA and partners to prepare for illness and death, but also it can create relationship difficulties. Anticipating health problems, HIV+ partners may withdraw from relationships and limit social participation. With disease progression, illness and medication side effects can also impair functioning to the degree that relational behaviors, even as mundane as hand-holding, become difficult or impossible. Some caregivers and partners find it difficult to maintain relationships with PLWHA and also may withdraw. However, caregivers also report that coming to terms with a partner's impending death is important for their own well-being.

Despite medical advances, PLWHA still suffer from opportunistic infections and health problems. Individuals whose partners die mourn not only their partner, but also the loss of significant relationships and parts of their own identity. In addition, surviving HIV+ partners in seroconcordant couples may view their partner's death as foreshadowing their own, making grieving even more difficult.

Conclusion

Like other chronic illnesses, there are many relationship issues to consider with HIV and AIDS. Primary among these issues are the roles that relationship closeness plays in increasing or decreasing sexual behaviors that put individuals and couples at risk for HIV, the benefits and stress associated with social support and care for PLWHA, and coping with illness and the potential

of premature death among PLWHA and their relationship partners. Considerable research has explored these topics to date, but additional scientific and clinical work is needed that explores HIV transmission and care among couples, families, and social networks in diverse populations and in different cultural contexts.

ALCOHOL AND SEXUAL ASSAULT

Alcohol is involved in approximately half of all sexual assaults. Alcohol contributes to sexual assault when either the victim or perpetrator has been drinking alcohol and it alters their perceptions and judgments. Victims' extreme intoxication can also be used by perpetrators as a tactic to obtain sex from individuals who are unable to give consent because of their mental incapacitation.

More than 80 percent of sexual assaults occur within the context of a relationship, ranging from casual acquaintances to long-term sexual partners. The characteristics of alcohol-involved sexual assault are difficult to specify without first describing the general characteristics of sexual assault. Thus, this entry defines sexual assault and alcohol-involved sexual assault, describes their prevalence, and briefly summarizes what is known about their causes and consequences.

Definitions and Prevalence Information

Most researchers define sexual assault as any type of forced sexual activity obtained against the victim's wishes or when the victim is unable to give consent. Thus, it includes acts of physically forced vaginal, oral, or anal penetration that constitute rape. Sexual assault also includes physically forced sexual touching and the use of verbally coercive tactics that may not conform to legal definitions of criminal sexual contact but have negative consequences for victims. In most jurisdictions, sex with someone unable to consent because of permanent or short-term mental incapacitation constitutes rape. Although the media has dramatized cases in which potent drugs such as flunitrazepam (i.e., Rohypnol) have been given to victims without their knowledge, alcohol is the most commonly used date-rape drug.

Alarming high rates of adolescent and adult sexual assault have been documented in surveys that have been conducted in the United States since the 1980s. Sexual assault prevalence has been less well documented in most other countries; however, available data suggest that rates are high throughout the world. The United Nations has documented the frequent use of rape as a tool of war. Crime statistics are notorious for underestimating rates of sexual assault because only a small proportion are reported to the authorities. Also, most people still think of sexual assault as an attack by a stranger; thus, when sexual assault occurs within the context of an ongoing relationship, people are not always sure how they should label it. Consequently, researchers prefer to ask questions that describe sexually assaultive experiences in lay language without using terminology that labels the behavior. Commonly used questions ask about

situations in which someone used physical force or verbal pressure or situations in which the person was so drunk or high he or she did not know what was happening. Using these definitions, approximately one in five American women are likely to be victims of physically forced penetrative sex and another third will be the victim of some type of forced sexual contact. Men are also victims of sexual assault, but at much lower rates. In a large representative study of rape victimization sponsored by the Department of Justice, more than 80 percent of male victims were raped by a man. Sexual orientation is seldom assessed in these surveys; thus, there is limited data about the victimization of gays and lesbians.

Although there is variability across studies, approximately half of sexual assaults involve alcohol consumption. Most studies have not asked victims or perpetrators how much alcohol they consumed, thus the level of intoxication varies from modest to severe. Victims who were too intoxicated to consent usually report being passed out during all or part of the assault. Usually if either the victim or perpetrator consumed alcohol, then they both did. In social settings, people frequently drink together; in fact, research has demonstrated that people view it as atypical when one member of a couple drinks alcohol and the other does not.

Explanations for the Relationship Between Alcohol and Sexual Assault

The fact that alcohol and sexual assault frequently co-occur does not prove that alcohol causes sexual assault. Most researchers believe that the relationship between alcohol and sexual assault is complicated and that there are several pathways through which alcohol increases the likelihood of sexual assault. Focusing on perpetrators' personality characteristics such as impulsivity and a lack of social conscience have been linked to both heavy drinking and sexual assault. Thus, some of the association between drinking and sexual assault perpetration is thought to be due to other shared causes. Although the usual presumed causal direction is from intoxication to sexual assault, ironically, alcohol is such a well-known excuse for engaging in disinhibited and socially disdained

behavior that some individuals drink precisely because it provides a convenient justification for inappropriate behavior. In these cases, the desire to engage in sexual aggression may precede the decision to drink alcohol.

The relationship between alcohol consumption and sexual assault victimization is also complex. There are high rates of post-traumatic stress disorder among sexual assault survivors. Some victims begin to drink heavily after childhood or adult sexual victimization as a means of managing their symptoms. Although this may reduce their anxiety in social and sexual situations that remind them of the sexual assault, it also puts them at risk of revictimization. Many perpetrators encourage female companions to drink heavily or look for intoxicated women at parties or bars because these women are viewed as easy targets.

Alcohol's effects on behavior are usually grouped into two categories: psychological effects and pharmacological effects. Every society has beliefs about how alcohol affects behavior. In American society, alcohol is viewed as a sexual aphrodisiac that enhances sexual desire and performance. Alcohol is also thought to make people more aggressive. People tend to see what they expect to see in social situations; thus, when drinking alcohol, ambiguous behavior is often perceived as conveying sexual or aggressive intent. On its own, this perception should not cause sexual assault; however, many male perpetrators have hostile cognitions about women and view women as sexual commodities who "owe them" once they are sexually aroused. Thus, for some male perpetrators, beliefs about alcohol's effects reinforce their beliefs about women and consequently serve to further justify sexual aggression.

Pharmacological effects of alcohol also appear to play a causal role in sexual assault. Alcohol consumption impairs cognitive functioning, especially the ability to integrate and interpret complex information from multiple sources, to engage in problem solving, and to inhibit well-learned behavior. These effects begin with just two drinks (a blood alcohol level of about .04) and increase as the dose increases. Researchers interested in aggression have brought men into a laboratory and randomly assigned them to drink alcohol or a placebo beverage. Drinkers respond much more aggressively toward others than do nondrinkers, especially

when they believe the other provoked them. Of course actual sexual aggression cannot be examined in a laboratory; however, researchers have interpreted these findings as supporting the argument that intoxicated men feel more justified about using force to obtain sex than do sober men. Other researchers have asked men to react to a date rape scenario and found that intoxicated men report more approval of the perpetrators' behavior and greater willingness to consider acting similarly as compared to sober men.

This research paradigm has also been used with women to determine their ability to recognize potentially risky social situations. Several research teams have demonstrated that as compared to sober women, intoxicated women report that they would engage in riskier behavior with a man they liked but did not know well, such as going to an isolated place with him. Researchers in this area emphasize that women should not be held responsible for trusting a man and that sexual assault is always the fault of the perpetrator. However, information about factors that increase the risk of sexual assault victimization can be used in risk-reduction programs.

Characteristics and Consequences

One important area of research involves identifying unique characteristics and consequences of alcohol-involved sexual assaults. Most sexual assaults occur in the context of social situations. This is also true for alcohol-involved sexual assaults, although, not surprisingly, they are more likely than other sexual assaults to involve time spent together at a party or bar and with groups of other people. In young, unmarried populations such as college students, sexual assaults that involve alcohol also tend to occur among individuals who know each other less well than sexual assaults that do not involve alcohol. Based on victims' narratives, common situations involve spending time at a party with someone one knew casually from class or work and then agreeing to go somewhere more isolated with that person. Typically, the victim is attracted to the perpetrator and is interested in developing a relationship prior to the forced sex. When victims are extremely intoxicated,

completed rapes are more common because alcohol's effects on motor skills makes it difficult to resist. When perpetrators are extremely intoxicated, they are more violent, but they are also less likely to complete the rape because of alcohol's effects on their motor skills.

Some research has also compared the characteristics of perpetrators who commit sexual assault when intoxicated to perpetrators who commit sexual assault when sober. Although sexual assault perpetrators are heterogeneous and there is no one profile that describes them, multiple studies have demonstrated that as compared to nonperpetrators they are more likely to have experienced sexual or physical abuse in childhood, have engaged in delinquent behaviors in adolescence, have peers who approve of engaging in violence against women, have more hostile attitudes toward women and relationships with women, are more likely to view sex as an act of dominance, and have more positive attitudes about casual sexual relationships. This pattern does not appear to differ for perpetrators who commit sexual assault when intoxicated. The primary domains in which they differ from perpetrators who commit sexual assault when sober is in their impulsivity and in their attitudes and behavior regarding alcohol. They tend to be more impulsive, heavier drinkers and to believe more strongly that alcohol enhances their sexual drive and is used by women to signal their sexual interest. Thus, the motives of intoxicated perpetrators and sober perpetrators do not appear to differ in most domains, only the circumstances in which they feel comfortable committing sexual assault.

Sexual assault has a profound negative impact on its victims. Survivors show great resilience but also have high rates of post-traumatic stress disorder. Because sexual assault most often happens among people who know each other, in social relationship contexts in which victims believed they could trust their perpetrators, social anxiety and difficulty establishing trust within relationships are common consequences. Traditional stereotypes about women's role as gatekeepers who should control men's sexual impulses are still common and encourage victim blame. Some research suggests that victims are more likely to be blamed by others when they were intoxicated during the assault; drunken women are perceived as more sexually

loose and deserving. Although the victim's inability to give consent due to intoxication is a part of the criminal code in many jurisdictions, in practice, intoxicated victims are often derogated and their cases are rarely prosecuted. Some victims turn to alcohol, prescription medications, and illicit drugs after being sexually assaulted in an attempt to lessen their anxiety, fear, and depression.

ALCOHOLISM, EFFECTS ON RELATIONSHIPS

Alcoholism has pervasive effects on relationships. It also can be powerfully affected by relationships, such as those formed in recovery. For whom, how, and under what circumstances are alcoholism's effects seen? This entry describes the relationships affected by alcoholism, what these effects are, how they come about, and the circumstances that intensify or deintensify the effects. After defining terms and identifying relationships and situations affected by alcoholism, this entry also considers relationships in recovery from alcoholism.

Definitions and Extent of Problem

An individual with *alcoholism* meets the criteria for alcohol *dependence*; that is, there is craving, loss of control over drinking, tolerance (needing to drink more to experience the effects), and physical dependence (experiencing withdrawal when not drinking). Alcoholism is accompanied by profound impairments of relationships, at school, work, and family. Someone who *abuses* alcohol (drinks too much, too often, but has not experienced tolerance or withdrawal) may not technically meet the definition of an alcoholic, yet there are often serious problems in their important relationships. Among college students, heavy drinking, such as frequent binge drinking (the consumption of four, if female, or five, if male, drinks on one occasion) is associated with romantic relationship quality. For example, the more frequent the binge drinking, the greater the communication problems and the less the relationship quality with romantic dating partners. Thus, relationship problems and heavy drinking co-occur even in the absence of a clinically recognized diagnosis of alcoholism.

According to the U.S. National Survey on Drug Use and Health, during the years 2002 through 2004, there were 18.2 million people ages 12 and older who were alcohol dependent or alcohol abusers. Almost 20 percent of young adults, 18 to 25, met the criteria for alcohol dependence or alcohol abuse. These percentages declined steadily with age.

Of considerable concern are the 1.5 million youth, 12 to 17, who needed alcohol treatment—only 111,000 received it. Also of concern are the more than 6 percent of those alcoholics 18 and older who lived with at least one child under 18, accounting for approximately 5 million households.

In terms of demographic characteristics, for every 33 women who meet the criteria for alcohol dependence and abuse, there are 66 men. Of those who actually receive treatment, about 70 percent are men compared to 30 percent who are women. Factors that hinder women from seeking treatment include concerns for the care of children in the home, fears of having children removed, or if pregnant, being arrested for endangering a fetus. Ethnic groups in the United States vary, with the highest rates of alcoholism among Native Americans and the lowest among Asian Americans. Marriage is less likely for alcoholic adults, and divorce, more likely. Across these variations by age, gender, ethnicity, and marital status, almost 8 percent of the U.S. population from adolescence through old age abuses alcohol. Moreover, each alcoholic is part of a social network whose members are affected by the alcoholic's behavior.

Relationships Affected by Alcoholism

A life-span approach to alcoholism suggests that it is important to consider the effects of alcoholism on relationships at different stages of the life course. This life-span approach begins with infants. In any given year, some 40,000 children are born with Fetal Alcohol Spectrum Disorder (FASD); a range of effects occur in children whose mothers drank alcohol during pregnancy. A number of these children are born alcohol dependent and suffer withdrawal at birth. Such infants are fussy, with difficult temperaments and poor bonding with caregivers. FASD is associated with life-long difficulties in cognitive, physical, and social development.

Children and adolescents can become alcoholics. The earlier a child begins drinking, the more severe the problems with alcohol. Developmental tasks of childhood and adolescence include learning prosocial skills in order to initiate and maintain appropriate relationships with peers, parents, and other adults. Heavy alcohol use among children is

associated with serious fights at school or work, group-against-group violence, and harmful attacks on another. Such behaviors hinder positive social relationships. Siblings may be sources of alcohol and provide encouragement for consumption. Observations from clinicians suggest considerable tension, stress, and family dysfunction when a child in the family is an alcoholic.

The alcoholic child may be the offspring of alcoholic parents. Children from alcoholic families (COAs) have a greater likelihood of experiencing alcoholism and other problems. In households with an adult alcoholic, there are generally more arguments, insults, and yelling than in households without such an adult. The households may be embedded in poorer neighborhoods that include poverty and instability. Research has found a particular risk for boys whose alcoholic fathers are also antisocial. Poorer social adaptation, more violence, and more frequent divorce and separation characterize the family relationships of antisocial alcoholics. As they develop, the boys reflect the environments to which they have been exposed.

Even if a child has an alcoholic parent, there are protective factors. Children fare better when the alcoholic parent is not antisocial. Protection of family rituals and functioning from the alcoholic's behavior appears to be an important factor for better child outcomes. Having a childrearing environment with attention from an important nonalcoholic adult (such as a grandparent or coach) is also protective, as is being female and enacting the hero (e.g., responsible or achieving) role in the family. Children growing up in alcoholic homes have several possible developmental pathways; unfortunately, some of these come with very painful ramifications for close relationships.

Although alcohol's causal role in interpersonal violence is complex, alcohol use by the perpetrator, victim, or both is a frequent aspect of violence in society and in the domestic arena. Between 28 percent and 86 percent of U.S. homicides involved drinking. Greater violence accompanies greater alcohol consumption in dating and married relationships. Courtship violence is often based on a foundation of drinking and is implicated in date rape. Women's alcohol use is a significant factor in the risk for being physically assaulted. And after experiencing an assault, women's use of alcohol may increase substantially. Violent drinking spouses

used alcohol as an excuse for misbehavior and held expectations for aggression after drinking. Drinking that was coupled with expectations of behavioral undercontrol following drinking was the strongest predictor of domestic violence.

The peak years for alcoholism and alcohol abuse occur in young adulthood, a crucial time for building lifelong relationships with peers and romantic partners. Regulating behaviors and emotions appears to play an important role for young adults. Those from alcoholic families where there is family dysfunction have lower levels of emotion regulation and, in turn, greater problems with alcohol. Greater problems with alcohol are also associated with more problems in developing and maintaining close relationships with friends and romantic partners.

Marriage in young adulthood is a turning point in substance use and is associated with declining rates. Thus, the trend toward increased age at marriage could adversely impact the rates of alcoholism in the 18-to-25 age group. Remaining single longer increases the time span of heavy drinking that could lead to an alcoholism diagnosis. Despite the potential beneficial effects of marriage, marriage does not completely eliminate the effects of parental alcoholism on COAs' substance use and relationship quality. Unknown is whether it is legal marriage or pairing with a significant romantic partner that is associated with the reduction in substance use.

Young adult and adult relationships affected by alcoholism include both heterosexual and non-heterosexual relationships. Alcohol misuse among gay and heterosexual men appears to be fairly similar. Greater alcohol misuse occurs among lesbians compared to heterosexual women. Conclusions such as these depend on the person's age and timing of the assessment. For example, gay men increase their alcohol consumption in the transition from high school to college, whereas lesbians' intake levels off. Childhood risk factors such as parental alcoholism may be involved in alcohol abuse among adult lesbians. The differences among gay men, lesbians, and heterosexuals have been attributed to *minority stress*, the experiences of stigma, prejudice, and discrimination that create stressful environments. However, research that provides identification of a person's sexual orientation and drinking patterns does not provide information on

whether the person is in a relationship and how rates of drinking affect that relationship. How alcoholism affects lesbian, bisexual, and gay relationships is not well understood.

Drinking history and changes accompanying aging may contribute to alcohol dependence in older adults. For some older people, the aches and pains of aging as well as the losses of friends and family are alleviated with alcohol. These patterns of alcohol consumption can accelerate the onset of alcoholism in elders more rapidly than in younger adults. Illnesses of advancing age become worse when drinking is involved. As many as a fifth of hospital admissions of adults over 40 were diagnosed with alcoholism. Older adults who drink are not necessarily detected in visits with their physicians. For example, older women are simply not screened for alcoholism. Older men are only slightly more likely to be screened. Regardless of diagnosis, the older person's alcoholism presents difficulties for the spouse, children, and caregivers.

Alcoholism, Recovery, and Effects on Relationships

How does a family member with alcoholism enter into treatment or the recovery process? It is often through relationships. A family member may be instrumental in providing a bridge between the family member with alcoholism and the recovery community. In a family intervention, alcoholics hear from family members and close others about the ways in which the alcoholic's behavior has affected them. Sobriety within the context of programs such as Alcoholics Anonymous involves a prominent role for both the group's fellowship and the mentorship of the sponsor, the person who has more time and quality of recovery.

Families with a member undergoing treatment or recovery from alcoholism often experience additional difficulties in their relationships after the alcoholic goes for treatment. Old roles are dismantled; the alcoholic in recovery is now a hero for ceasing to drink. The former spouse who held it all together loses the need to overfunction and the control that went with it. The children who accepted adult roles now are expected to be children, and those children who acted out the family trauma are now without a cause. If the family alcoholic is an adolescent instead

of a parent, the difficult dynamics are just as evident. Parents want to "hover" and once "good" siblings lose such roles when the recovering adolescent assumes a hero mantle. Thus, family members may wonder if no good deed goes unpunished, as relationships become worse before they get better. Family members benefit from professional help in adjusting to and renegotiating relationships with the alcoholic in recovery. Despite the difficulties of the recovery process, without recovery any improvement in relationships would be unlikely.

ALIENATION AND ANOMIE

This entry describes two related concepts: *alienation*, an idea developed by political economist Karl Marx, and *anomie*, a concept at the heart of Émile Durkheim's intellectual work on social integration. Although there is some conceptual overlap, each is addressed separately below. The entry first explains alienation starting with Marx's initial formulation as it relates to the forces of capitalist development and then follows with some more recent applications. It then provides an overview of anomie, beginning with Durkheim's original use of the concept and then identifies some of the ways it has been used in contemporary research.

Alienation

Karl Marx saw alienation as an outcome of a particular mode of production in which fundamental human relations are undermined. In capitalist economies, Marx theorized, workers are separated from the products they produce, they do not control the production process, they are socially isolated from their fellow workers, and they are denied the natural benefits of engaging in meaningful work. The relations of production in modern capitalism represented a change from previous economic arrangements in which people generally had more control over their work and the products they produced. With the advent of industrial capitalism workers began receiving wages in exchange for their labor while the capitalists appropriated the products workers produced. Because the fruits of their labor now become the property of the owners, they appear as alien objects, disconnected from the workers and the human labor that created them. And because workers no longer controlled the terms, conditions, or products of their employment, they also became estranged from the production process itself. As inherently social creatures, Marx believed humans thrive on cooperation and the pursuit of common goals, but because capitalism demands competition, it forces workers to act in opposition to their collectivist nature and isolates people from one another as they pursue their individual

self-interests. As Marx saw it, industrial capitalism divorced workers from the fruits of their labor, made them into cogs in the machinery of production, and created adversarial relationships between workers. The result was a fundamental dehumanization of workers that he called alienation.

Although alienation is a useful concept in understanding modern relations among workers and between workers and production processes, today the idea is less frequently used in its original Marxian formulation. However, George Ritzer's work on what he terms *McDonaldization*, an extension of Max Weber's critique of mechanization and rationality, suggests a link to Marx's notion of alienation. According to Ritzer, modern societies value efficiency, control, calculability, predictability, and the use of technology. One result is that human labor is replaced by nonhuman technologies that make workers interchangeable and easily replaceable. Consequently, work loses its intrinsic value and becomes unrewarding and dehumanizing for many. People with little autonomy and control over their work lives may experience frustration and anxiety that can affect their relationships with coworkers as well as their personal relationships outside of the workplace.

One can also see the concept of alienation in the work of Robert Putnam, who applies it to his analysis of contemporary political culture. Putnam contends that changes in modern social arrangements have led to a reduction of participation in civic organizations, indicating that people are becoming more socially isolated. As a result, the sense of community, social solidarity, and common goals give way to an increasingly atomized civil society. As people disengage from community life and participation in traditional institutions of civic engagement declines, Putnam fears that the viability and vitality of democratic society will suffer.

Anomie

Durkheim defined the concept of anomie as a state of normlessness that reflected a breakdown of society's mechanisms of social regulation. Durkheim noted that during periods of rapid social change, traditional norms no longer were able to serve their disciplinary function to maintain social equilibrium. Central to his conceptualization of anomie

is the notion of the collective conscience, which represents the beliefs, values, and expectations shared by members of a society. Under normal circumstances, the collective conscience guides the behavior of individuals and establishes accepted goals and expectations. However, periods of rapid change often lead to uncertainty about how people should act and what they should expect from life. In his seminal work on suicide, Durkheim demonstrated that societies undergoing significant change also experienced higher rates of anomic suicide. People in rapidly changing societies were less likely to be deterred from taking their own lives, Durkheim theorized, because with the collective conscience in flux, it could not function as a mechanism of social control.

Robert K. Merton used anomie to explain deviant behavior resulting from the tension between dominant cultural values and goals and insufficient access to legitimate means of attaining them. This tension leads to deviant behavior when people without access to acceptable means adopt illegitimate ways of pursuing culturally valued goals. One can also see the concept of anomie reflected in Arlie Russell Hochschild's analysis of women's participation in the paid workforce and the impact it has on family life. She finds that although cultural expectations regarding women participating in the workforce have changed, traditional gender roles pertaining to family responsibilities have not. Women continue to do a disproportionate share of the housework relative to men even though they are likely to also work outside the home. This inequity often leads to marital tension and stress for both partners—reflecting a state of anomie due to uncertainty over gender norms and the division of labor in the household.

ALTERNATIVE RELATIONSHIP LIFESTYLES

A relationship lifestyle is considered alternative if it varies from what society deems as the cultural norm. In current U.S. cultural context, an alternative relationship lifestyle is one that does not fit the heterosexual nuclear family model in which there is a married husband and wife with children under the age of 18 living together in the same home. It is worth noting that sociological research indicates that historically not only has the status and definition of the model relationship or model family been constantly in flux but also what has been considered the ideal has not always necessarily been the norm. For example, although the number of people who currently live in a nuclear family in the United States is relatively low, this type of family continues to be upheld as the ideal model. Contemporarily speaking, there are a variety of relationships that challenge the nuclear model, and this entry will discuss some of the most common.

Cohabitation

One of the most increasingly common alternatives to the nuclear model is the prevalence of different-sex cohabitation before marriage. Cohabitation refers to two intimately involved, unrelated adults, who live in the same residence. According to the 2000 U.S. Census, there are 4.9 million unmarried different-sex households. The rates of cohabitation are even higher in many European countries.

Research indicates that cohabitation in the United States is a contemporary stage for many in the trajectory toward legal marriage. About half of all Americans cohabit before marriage, and within the first 5 years, about 55 percent of cohabiting couples will marry and 40 percent will break up. Despite that many cohabiting couples may desire to enter the nuclear family model, they still challenge the ideal, which was once more commonly held, of sexual abstinence before marriage. The 2000 U.S. Census indicates that 41 percent of cohabiting households have children under the age of 18 sharing the home.

Committed Unmarrieds

Of the different-sex couples that cohabit, some are committed in their relationship but consciously choose to be unmarried and do not view cohabitation as a step toward legal marriage. The reasons people choose to be marriage-free vary; for example, some decide not to marry as a form of active resistance to the traditional gender roles that historically define husband and wife. Other research indicates that some heterosexual couples choose not to legally marry because they feel as though marriage is an exclusionary institution that actively discriminates against gays, lesbians, and polyamorous family groupings. In addition, there is evidence that people forgo legal marriage because of their fear of divorce, financial penalties, inability to afford or conscious revolt against the expenses associated with the marriage ceremony itself, and the desire to limit the role government and religion play in their lives. Finally, some people choose not to legally marry because they simply do not feel any need or desire to do so and because they do not feel as though marriage would change their level of relationship satisfaction or commitment.

Same-Sex Relationships

In the United States, heterosexuality is upheld as the cultural ideal, and thus, same-sex relationships are viewed as alternative. Despite being viewed as unconventional, the 2000 U.S. Census indicates there are 1.2 million Americans living with a same-sex partner, of which, male same-sex couples accounted for a slightly higher percentage (51 percent) than

female same-sex couples. Some same-sex couples, and individuals, wish they had the legal right to enter into the institution of marriage, whereas some same-sex couples, or individuals, do not. In any case, the question as to whether or not the right to legally marry should be extended to same-sex partners has been at the forefront of many contemporary political debates and has occupied a good deal of the time in many state and federal legislatures, both domestically and internationally. Currently, Belgium, Canada, The Netherlands, South Africa, and Spain allow same-sex marriages. In the United States, as of January 2009, Massachusetts is the only state that extends the legal right to marry same-sex partners. According to the 1996 Defense of Marriage Act, the federal government does not recognize same-sex marriages, thereby leaving the decision to the discretion of each individual state and giving each state the right to refuse to recognize same-sex marriages licensed in other states. As such, same-sex couples who legally marry in Massachusetts are not entitled to any federal marriage benefits and are not likely to have their marriage recognized by any other state. Other states have created marriage alternatives for same-sex couples. Vermont, Connecticut, New Jersey, and New Hampshire have a legal civil union option; a handful of states (e.g., California, Oregon) and a variety of counties have domestic partnerships available. It is commonly understood that these alternatives are not equally comparable to legal marriage, as they do not grant the same privileges, are not nationally recognized, and are often publicly and legislatively contested.

Part of the controversy over same-sex relationships and marriage rests on the issue of children. Nearly one quarter of same-sex couples in the United States are raising children. Many of the children are from prior heterosexual marriages or relationships; some children are products of the same-sex relationship with the aid of assisted reproductive technology or adoption. As same-sex parenting strays from the heterosexual parenting ideal, same-sex couples and gay and lesbian individuals face challenges involving child custody, visitation, adoption, and fostering.

Transsexual and Intersexual Relationships

Although gay-, lesbian-, and bisexual-identified individuals challenge the ideal of heterosexuality,

transsexual- and intersex-identified individuals challenge most society's strict adherence to the gender dichotomy of male and female. Colloquially referred to as hermaphrodites, intersex individuals are born with mixed or ambiguous genitalia and thus have anatomy that does not fit the typical definitions of male or female. A relationship involving an intersex-identified person complicates the common cultural assumption that there are only two distinct biological sexes. Individuals who identify as transsexual, identify with the gender opposite the one assigned to them at birth, and some choose to undergo hormone therapy and/or surgery to align themselves with the sex with which they feel identified. Again, a transsexual-identified person complicates the assumption of two distinct and different sexes and the ideal of heterosexuality.

Child-Free

American society is essentially pronatalist in which heterosexual married couples are encouraged to have children. Thus, different-sex couples who choose to remain child-free can be considered living an alternative lifestyle. There are myriad reasons why people choose not to have children, for example, the desire to succeed in careers, economic concerns, concerns about overpopulation, desire for independence, or a general dislike of children. Not having children is not a conscious decision for all child-free couples, as some are unable to conceive. The assumption that married couples will have children is so culturally ingrained that often child-free married couples not only receive pressure to have children but are also judged negatively for not reproducing.

Polyamory

A key tenet of the nuclear family model rests on the assumption of sexual and emotional monogamy between two heterosexual people. Polyamorous relationships offer a distinct challenge to these assumptions. Polyamory (from the Greek *poly* meaning many and the Latin *amor* meaning love) is an umbrella term that refers to the philosophy and practice of engaging in simultaneous, openly conducted, and nonmonogamous relationships. As

a philosophy, polyamory stresses the importance of consciously choosing how many partners one wishes to be involved with rather than accepting the social norm of loving only one person at a time. The relationships themselves vary in form, but they are based on emotional intimacy, long-term connections with multiple lovers, and with the goal of feeling joy in a partner's enjoyment with another person, known as *compersion*. Sometimes referred to as *responsible nonmonogamy*, polyamory differs from the practice of *swinging* in that the relationships are based on emotional commitment and not on casual sex. The number of people involved in each polyamorous relationship varies, as does the level of sexual involvement, emotional commitment, and the gender and sexual orientation of the participants. Additionally, some polyamorous groupings parent children, while others do not. Since the census does not recognize polyamorous relationships and many polyamorous people are unable to publicly declare their affiliation, the actual number of people identifying as polyamorous is unknown. Although the exact numbers may be unclear, attendance at polyamorous conferences and events, activity on polyamorous Internet sites, and sociological research all indicate that this is a thriving, albeit often misunderstood, community.

Polygamy

Because of the emphasis on egalitarian relationships, the allowance for different sexualities, and its independence from a specific religious tradition, polyamory differs from polygamy. Polygamy is the practice of having more than one spouse. In the United States, some practice polygyny, which is the practice of a husband having two or more wives at the same time. Polygyny in the United States is illegal and primarily exists in religious fundamentalist groups predominantly in Arizona, New Mexico, and Utah. The practice originates from Latter-Day Saints (LDS; Mormon) scripture and the revelations of Joseph Smith, who taught that men need at least three wives to attain the "fullness of exaltation" in the afterlife and that wives are required to be subordinate to their husbands. The LDS church officially banned the practice of polygyny, known as *plural marriage*,

in 1890. Although a difficult population to count, an estimated 40,000 people in Utah and surrounding areas identified as fundamentalist Mormons, of which probably fewer than 50 percent live in plural marriages. Currently, the U.S. polygynous community garnering the most public attention is the Fundamentalist Church of Latter-Day Saints (FLDS), which is a splinter sect of LDS and represents a very small percentage of all Mormons in Utah. The FLDS sect has had its difficulties, including accusations of children and women living in extreme poverty, sexual assault, sex with minors, the abandonment of young men to reduce competition for wives, and the recent sentencing of former FLDS leader Warren Jeffs on two counts of accomplice to rape.

There is a rich history of many cultures practicing polygyny to fulfill certain religious edicts, to earn wealth, to win political power, and/or to produce multiple heirs. Currently, polygyny is far less widespread and accepted than it once was. Cultures that practice polygyny today are largely concentrated in Africa, the Middle East, India, Thailand, and Indonesia. Much less common is polyandry, the practice of a wife having two or more husbands at the same time. Practiced to keep birth rates down in poor communities or when two brothers share one wife in order to keep one household, polyandry is only rarely found in some societies (e.g., in Tibet).

Additional Alternative Relationships

Although not a relationship lifestyle per se, it is worth noting that even though single individuals currently outnumber married couples in the United States, single people (either the never-married, the divorced, or the widowed) fall outside of the nuclear family norm. Single parents, either heterosexual, gay, or lesbian, also fall outside of the two-parent ideal. Married couples who do not always share the same home (e.g., commuter marriages) or couples who live in intentional communities (commonly known as *communes*) also challenge assumptions about the necessity of families living together in isolated dwellings.

The nuclear family model is so embedded in Western laws and regulations that individuals who fall outside of the cultural ideal, either by choice

or involuntarily, do so at the expense of social, legal, and economic privileges associated with legal marriage. Despite Western society's emphasis on monogamous heterosexual relationships, there have always been relationship lifestyles that vary from the cultural ideal. In fact, the existence and prevalence of so many alternative relationship lifestyles may call into question the very label of alternative.

ALZHEIMER'S DISEASE AND RELATIONSHIPS

The progressive nature of Alzheimer's disease has been called "the long goodbye" for good reason: Many losses occur along the illness trajectory. Some of these losses, such as *psychosocial death* (i.e., the loss of interpersonal relationship with the affected

person), may be even more difficult to manage for family caregivers than eventual bodily death. When someone is diagnosed with Alzheimer-type dementia, it is usually their spouse or adult child whose relationships with them are most affected. Currently, over 5 million people in the United States have Alzheimer's disease. Of those who have the disease, three fourths live out in the community, usually with family members. Equally impressive is the fact that 75 percent of the care given to people with Alzheimer's disease is provided by family members. This entry discusses the effects of Alzheimer's disease and the disease progression on family relationships. Before the impact of Alzheimer's on family relationships can be understood, it is critical to understand the disease itself.

Alzheimer's-Type Dementia

Dementia is a broad term that means a progressive decline in cognitive function. It can be caused by a number of conditions including Parkinson's disease, Alzheimer's disease, AIDS, vascular problems, stroke, malnutrition, severe alcoholism, and hypothyroidism. The American Psychiatric Association explains that this condition involves developing multiple cognitive impairments, including memory, and at least one of the following: aphasia (difficulty with language), apraxia (loss of fine motor skills), agnosia (loss of ability to recognize familiar people, places, and objects), or disturbance in executive function. In addition, the cognitive deficits experienced by the individual must be severe enough to cause impairment in daily functioning as well as represent a decline from a previously higher level of functioning. Although dementia can be caused by several different conditions, the most common cause of dementia is Alzheimer's disease.

Alzheimer's disease is a progressive brain disorder that usually causes the person to suffer from all of the cognitive impairments mentioned above. In addition, as the disease progresses, changes in behavior and personality often occur such as anxiety, suspiciousness, agitation, and delusions.

Some experts have described Alzheimer's as occurring in stages, with each stage ushering in new symptoms and additional cognitive decline. Arguments vary as to the number of stages

involved in the progression of the illness, but generally, physicians and researchers will agree upon three broad periods of impairment known as mild, moderate, and severe dementia—each corresponding to increasing levels of impairment. As people with Alzheimer's progress through these various stages, their relationships with family and friends experience increasing strain.

It is important to explain the multifaceted nature of Alzheimer's disease because it is often misunderstood by the general population as simply a memory disease, and therefore, the true devastation on the person and his/her family is underestimated. The most intense impact is usually felt by the family member who serves as the primary caregiver for the person with dementia. This is usually the spouse or an adult child.

Alzheimer's Disease and Changes in Spousal Relationships

For those who are married to someone with Alzheimer's disease, it is evident that no family relationship bears the brunt of the disease as much as the marital relationship. Roles are likely to shift or reverse as the partner with dementia is no longer cognitively able to perform many daily tasks or share in important household decisions. It is common for the couple to experience a loss of intimacy; changes in the sexual relationship; and feelings of guilt, fear, frustration, and great isolation.

For married couples, sexuality and intimacy are often adversely affected by the progression of Alzheimer's disease. Sexuality and sexual activity can be affected because of brain deterioration. Specifically, it is typical that people with Alzheimer's disease can experience an increase in their sexual drive, which sometimes leads to inappropriate sexual behaviors in public places. Alzheimer's can also result in paranoia among people with the disease, and this can be displayed with accusations of infidelity voiced toward one's spouse. Conversely, spouses of people with dementia often experience a reduced interest in sex due to the pressures of caregiving and personality changes in their spouses. Intimacy can also suffer because of the brain deterioration caused by Alzheimer's disease. The sense of closeness and warmth that the couple shared

may diminish because of imbalance in the roles and strain in daily life. Researchers point out that there are things that can be done to nurture intimacy despite the progression of the disease. Touch and physical contact are critical for the person with dementia. He or she will still be able to respond to a hug, holding hands, or touching of the forearm. People with Alzheimer's disease can experience feelings of reassurance, safety, and love through the simple touch and physical contact.

Changes in Parent–Adult-Child Relationships

Alzheimer's disease presents separate relationship challenges for adult children. Adult children may experience strong feelings of grief or loss as they mourn for the parent who is no longer "present." When interviewed, adult children who have a parent with Alzheimer's disease frequently make comments such as, "She is not my mom anymore" or "The person I knew as my father is gone." Experiencing these feelings of loss while the person with dementia is still alive is known as *anticipatory grief* and can be very debilitating for family members. Spouses experience anticipatory grief but usually not as strongly as adult children.

Another key relationship issue often cited by adult children is difficulty communicating with the parent who has dementia. Adult children voice concerns about understanding what their parent is trying to say as well as trying to communicate effectively with their parent. They want to be able to treat their demented parent with respect and love but also realize that their parent cannot interact the way he or she used to. The communication gap can leave adult children feeling conflicted and frustrated and certainly affects his or her relationship with the ill parent.

Sibling relationships can become strained as their parent's Alzheimer's worsens. Often it is one particular child (usually a daughter) that carries the brunt of the caregiver responsibilities. This particular child may feel resentment and anger toward her siblings and reduce communication with them, believing that this is the only way to avoid further disruption and stress for the person with dementia.

Both adult children and spouses of someone with Alzheimer's may experience feelings of isolation, especially if they are caregivers. Frequently, other relatives and former friends avoid contact

because they cannot face the deterioration of someone experiencing Alzheimer's disease. This leaves the spouse and/or the adult children feeling isolated and sometimes abandoned by those they had relied on in the past. Finally, as the disease progresses, there can be shifts in the family structure as a whole. Long-standing family conflicts between parents and children or between siblings can be exacerbated by the onset of Alzheimer's type dementia. Trying to effectively cope with these relationship changes can be challenging and emotional. Participating in Alzheimer's support groups is often a very successful and rewarding coping strategy for both spouses and adult children. Increasingly, there are also support groups available for people with Alzheimer's disease so that they have an outlet to discuss their feelings about the relationship changes they are experiencing.

AMBIVALENCE

The term *ambivalence* is often used to describe conflicting feelings and emotions in relationships. This entry discusses the definitions of ambivalence, predictors of ambivalence, and finally, the implications of ambivalence for well-being.

Definitions of Ambivalence

The definition of ambivalence has evolved over time and often varies by discipline. The term was originally coined in the 19th century by Eugen Bleuler, who defined ambivalence as having competing desires at different levels of consciousness. For example, an individual may verbally express a desire to change his or her life circumstances but exhibit behaviors that contradict those expressed desires. Sigmund Freud further developed this definition in his description of ambivalent feelings as the experience of love and hate toward the same object. Ambivalence is also used in the attachment literature to describe a particular attachment style (anxious-ambivalent). Children with this attachment style are uncertain about their primary caregiver's ability to provide support and thus show inconsistent behaviors toward the caregiver (usually a parent). This type of ambivalent attachment in adulthood is defined as having conflicting opinions about whether a person can be trusted in a relationship. Similarly, ambivalence is used in the romantic relationship literature to describe feelings of confusion and anxiety about whether the relationship should continue.

Ambivalence is also defined by sociologists as incompatible expectations that exist in a social status or role that lead to contradictory attitudes or expectations for behavior. According to this approach, people with fewer social and economic resources are more likely to experience ambivalence.

For the purpose of this entry, ambivalence is defined as having positive and negative emotions or cognitions about the same relationship. This definition of psychological ambivalence is used in a great deal of the adult relationship literature to characterize strong negative and positive feelings in relationships. For example, a person may experience both intense love and irritation regarding his or her spouse. Such ambivalence is distinct from feelings of confusion and/or indifference in which the relationship may include low levels of both positive and negative feelings. In addition, this type of ambivalence is distinct from feelings of confusion.

Measurement of Ambivalence

Psychological ambivalence can be measured directly or indirectly. Direct measures ask participants to

estimate how mixed their feelings are about a relationship. For instance, participants may be asked how often they feel torn in two directions, conflicted, or that the relationship is very intimate as well as restrictive. Indirect measures combine positive and negative assessments of relationships to create an ambivalence score. Examples of positive items may include qualities such as loving, supportive, and understanding. In contrast, negative items often include qualities such as rejecting, demanding, and critical. Thus, high levels of ambivalence reflect both high levels of positive and negative feelings.

Predictors of Ambivalence

Ambivalence varies by contextual as well as individual difference factors. A contextual factor of particular importance is the type of relationship. Individuals are more likely to experience ambivalence in close family relationships than in non-family or extended-family relationships. A possible explanation may be that nonfamily relationships involve clearer norms for behavior that are less likely to conflict than do close family relations. For example, close or immediate family relationships often involve conflicting needs of closeness and autonomy. Close family ties also have a longer history that provides more opportunity for tensions. Indeed, ambivalent feelings may occur when a relationship was negative in the past but is currently positive or when relationships that were once positive have become negative. In addition, close family ties in particular (parent, child, spouse) involve more frequent contact and greater feelings of obligation than do extended-family and nonfamily ties.

The adult intergenerational research in particular has established that ambivalence is most likely to occur when there are conflicting needs for independence and closeness in relationships. Both parents and adult children desire independence from one another as well as cohesiveness. When an imbalance occurs between those desired attributes, both parents and children tend to experience more ambivalence. For example, parents are more likely to report ambivalence when their adult children have not achieved expected adult statuses (e.g., career, children), when their

children have financial problems, or when they do not visit their parents often enough. Adult children, on the other hand, tend to feel ambivalent when they experienced parental rejection earlier in life or when they anticipate having to provide support for elderly or sick parents. Overall, adult children tend to report greater ambivalence than do their parents across situations.

It is important to note that ambivalence also varies by individual differences including demographic and psychological factors such as age, gender, and personality. Older people tend to report less ambivalence across their social network members than do younger people. Women tend to experience more intense positive and negative emotions in relationships. Thus, women are generally expected to report experiencing greater ambivalence than do men; however, the research is inconsistent. Ambivalence also varies by personality. People who have more neurotic personality types report greater ambivalence in their relationships.

Implications of Ambivalence

Overall, ambivalence has negative implications for well-being and relationship satisfaction. Researchers have found that ambivalence predicts depression, lower quality of life, physiological reactivity, and lower relationship satisfaction. For example, ambivalent relationships are associated with lower self-reported well-being than solely negative relationships. Research also shows that older people who have more ambivalent relationships have greater cardiovascular reactivity to stress in the laboratory. Further, ambivalence is associated with increased interpersonal stress. The romantic relationship literature indicates that feelings of ambivalence during the early stages of the relationship (e.g., casual dating) are associated with greater conflict, whereas during the later stages of courtship (e.g., marriage) ambivalence is associated with lower love. Finally, parents who feel greater ambivalence regarding their children report lower quality of life. Bert Uchino provides two possible explanations for these findings: (1) ambivalent relationships are more unpredictable than solely negative or positive relationships, which may lead to increased distress, or (2) ambivalent ties cannot be depended on to provide

support when it is needed most. These two lines of reasoning provide interesting directions for future work in this field.

AMERICAN COUPLES STUDY

The American Couples study was funded by the National Science Foundation, and its signature book, *American Couples: Money, Work and Sex*, was published by Philip Blumstein and Pepper Schwartz in 1983. The book and subsequent academic papers were the result of more than a decade of gathering data from over 12,000 heterosexual and same-sex couples, obtained from diverse groups and volunteers over the United States. The design of the study was to compare four kinds of relationships—heterosexual married couples, heterosexual cohabiting couples, gay male couples, and lesbian couples—to address two overall questions. First, is marriage different from all other kinds of cohabitation and would married couples be different from all other kinds of couples? Second, would gender be more predictive than couple type or how people behaved in intimate relationships, therefore showing continuities between husbands, male cohabiters, and gay males and between wives, female cohabiters, and lesbians? Areas of investigation included levels of

overall satisfaction, couple durability, the importance of sex, sexual frequency, monogamy, division of labor, child raising, attitudes about money, money management, work and family attitudes, the impact of work and money on power, negotiation tactics, commitment, and durability.

The sample was nonrandom, but a stratified subsample was selected in order to look at potential differences that might be caused by the duration of relationships and other important variables. Variation in income, education, and age were also systematically introduced into the sample. Minorities were underrepresented, and differences between race and ethnic groups were not generally statistically reported.

The American Couples study was unique because it compared actual partners (rather than a sample of husbands and wives who were not necessarily married to each other) across the four kinds of couples. For many decades, it was the primary provider of comparative data on same- and opposite-sex couples in family textbooks. The raw quantitative data from the study is still housed at the Radcliffe Institute at Harvard and is available to scholars.

Some of the most interesting findings were about the power dynamic of couples, what created satisfaction in couples, and whether gender or type of relationship was likely to predict behavior. Overall, the authors found that money was highly predictive of power within all kinds of relationships, though least important for lesbians. Quite consistent with gender socialization, the authors found that if a gay male couple broke up, the leaving party was more likely to be the lower earning partner. This was just the opposite for lesbians—the higher earning woman was the more likely person to leave. In general, men did not like to be “provided for” and women did not like to be the primary provider.

On the other hand, institutional forces were often definitive. For example, married couples were the most likely to pool all their resources, to give the same answers on the questionnaires, to be equally committed, to have a traditional division of labor (one person predominating as the provider, the other much more in charge of domestic duties) and have longer durability. Domestic duties were more egalitarian in all three nonmarital types of relationships (the study was done before any

same-sex couples had legal standing). Interestingly, however, there were many instances when the married couples and same-sex couples were more like each other than they were like heterosexual cohabiters. This was interpreted by the authors as proof of the impact of commitment: Cohabiters were much more likely to disagree about how long the relationship was going to last compared to all of the other kinds of couples. They were the least likely to pool resources of any kind and the least likely to be generous about economic sharing.

Sexual frequency did not predict longevity in any of the four kinds of couples. However, the amount of sex varied widely depending on couple type. Sexual frequency declined greatly after the first year in a relationship, although more in married couples and lesbians than in cohabiters and gay men. Married couples went from three or more times a week to approximately twice a week or less. It may be that married couples could afford an attenuation of sexual activity since relationship commitment was more solid. Or some of this greater loss of sexual behavior could be accounted for by pregnancy or child bearing. All four kinds of couples had less sex based on increasing age and duration of the relationship. There were significant gender differences: Sex was more important to all the men in the different kinds of couples than to the women, and women were more likely to compartmentalize sexual dissatisfaction, while men were more likely to let sexual issues undermine relationship satisfaction in general. If women did not like their sexual life with their partner, it did not affect their evaluation of the entire relationship. However, if men were disappointed with their sex life, their total relationship happiness was less highly rated.

Initiation of a sexual event was generally male; in fact, each gay male partner in a couple was generally likely to claim that he was the initiator, and each woman in a lesbian relationship was more likely to claim that she was not the initiator of sex. This pattern may have affected the total frequency of sex in lesbians since each partner was reluctant to suggest having sex. On the other hand, lesbians were most likely to have nongenital affection such as hugging and kissing, and this type of affection may have made the need for genital sexuality less important.

There were, however, many facets of sexual intimacy that seemed to apply to all types of couples. Fighting about nonsexual issues (such as

money) correlated with higher breakup rates in all couples (while more equal control over money predicted more satisfaction); affairs correlated with breakups for all couples, although gay men could survive recreational (nonromantic or uncommitted) sex outside the relationship, which, at that time, was actually normative for male romantic relationships. Indeed, not only was nonmonogamy expected for gay couples, but also it was counter-normative to insist on monogamy. Satisfaction with sex correlated with relationship satisfaction for all four kinds of couples.

Although the American Couples study has been supplanted by newer studies in some of its findings (particularly in regards to gay male sexual behavior that has become more, although not entirely, monogamous in response to the high risk of AIDS infection and transmittal), the data still provide a fascinating look into how intimacy is affected by the structural norms and constraints of marriage and how gender traditions and changes affect sexuality, work, domestic duties, economic roles, and power.

ANGER IN RELATIONSHIPS

The term *anger* refers to a powerful human emotion, elicited when individuals perceive that their needs, desires, or goals have been thwarted or obstructed by others. Given that friends and family

members have the greatest capacity to thwart personal desires and goals, it is not surprising that researchers have found anger to be one of the most frequently experienced relationship emotions. It should be noted, though, that anger is not necessarily a negative or harmful emotion. Rather, anger is an innate, evolved psychological mechanism that serves an important survival function: Specifically, it alerts individuals to the fact that their goals have been obstructed and motivates them to attack the perceived source of the obstruction. Even so, although the experience of anger may be energizing and have potentially functional outcomes, angry individuals may also behave in aggressive and dysfunctional ways that exacerbate rather than resolve their relationship problems. These features and functions of anger in relationships are discussed in more detail in this entry.

Causes of Anger in Relationships

The first major survey of laypeople's experiences of anger was published by James Averill in the 1980s. Averill found that anger was a profoundly interpersonal emotion, experienced most often within relationship contexts and elicited by perceptions that others were behaving badly or in ways that violated important interpersonal rules and standards. Since the 1980s, a number of empirical studies have confirmed that almost any event or stimulus can elicit anger in relationships depending on how this event is appraised or interpreted by an individual. Specifically, to the extent that a stimulus (such as a partner's unwillingness to share household chores) is appraised as unwanted, undeserved, and "not right" (typically expressed as "unfair"), then an individual is likely to experience anger in response to that stimulus. Further, to the extent that the stimulus is appraised as intentional (i.e., one believes one's partner is being deliberately lazy) and controllable (i.e., one's partner is not physically disabled and knows how to operate a vacuum cleaner), then an individual's anger may be intense.

Other kinds of cognitive appraisals may moderate the experience of anger. For example, when the kinds of anger-eliciting appraisals described above are coupled with perceptions of powerlessness (i.e., one's partner clearly has no intention of ever

doing household chores), one may experience what Attachment Theorist John Bowlby referred to as a futile “anger of despair,” as opposed to the potentially functional “anger of hope.” Further, researchers have found that appraisals of powerlessness in anger-eliciting situations may be associated with feelings of hatred for the offending partner, whereas appraisals of actual and/or moral superiority may be associated with contempt. Overall, however, the key cognitions associated with anger concern perceived “wrongness” or injustice and other-blame. Little wonder, then, that some have referred to anger as the judicial emotion.

Motivational and Behavioral Features of Anger

Along with judgmental cognitions, anger is associated with powerful urges, or impulses to action. Physiologically, anger prepares the body for removing obstacles and winning battles. The angry individual’s heart rate and blood pressure rise, and he or she feels energized, focused, strong, and, importantly, right. Accordingly, researchers have found that a key defining feature of anger in relationship contexts is a desire to confront or engage with offending partners and make them see the error of their ways. Anger is also associated with powerful urges to punish offenders and/or to take revenge on them. Such desires may manifest in verbal and nonverbal displays of intimidating behaviors such as shouting, stamping, throwing objects, or displaying physical aggression and violence. Some individuals also express anger by ignoring, ostracizing, or attempting to inflict emotional pain on offending partners. Importantly, however, angry impulses are not always acted upon, particularly when such impulses are aggressive or destructive. Indeed, researchers have found that people typically report trying to control the expression of anger in close relationships, though there are some important gender differences in the ways in which men and women express and regulate anger.

Gender and Anger

Empirical research has shown that men and women are equally likely to be angered by perceived

injustice and equally likely to experience urges to express their anger and to take remedial and/or retributive action. However, researchers have also found that, compared to men, women’s vocal and facial expressions of anger are less clear. For example, women are more likely than men to report crying when they are angry, a reaction which can generate confusion in observers (“Is she mad, sad, or scared?”). In part, these expressive differences may derive from the widely held belief that anger is an essentially male emotion, associated with dominance and getting one’s own way. Certainly, in relatively nonintimate contexts such as in the workplace, anger displays are generally regarded as more acceptable for men than for women. Researchers have also demonstrated that within organizational settings, angry men are perceived by others as dominant and powerful, whereas angry women are perceived as weak and lacking control. Women report feeling unprofessional and less competent when they express anger at work. Within intimate contexts, however, women appear to feel more comfortable about expressing anger, and they are more likely to engage in confrontational and openly angry behaviors. In contrast, men are more likely than women to report using humor and distancing behaviors, as opposed to direct confrontation, when they experience anger within intimate contexts.

In part, these gender differences may be a function of perceived power. For example, researchers have found that in the workplace, superiors tend to express anger more directly than subordinates, who tend to withdraw and/or express anger indirectly for fear of the consequences. In many organizations, men are still more likely to hold positions of power than women; hence, their anger displays are more likely to be perceived as appropriate and acceptable. Within intimate, emotional contexts, however, men may feel relatively more vulnerable and less powerful than women, who may thus feel better able to express anger directly (and in particular, verbally) to their partners. In these circumstances, some men may tend to respond to their partners’ expressions of angry assertiveness with avoidant or distancing behaviors. On the other hand, researchers have found that men with insecure attachment styles may respond to feelings of vulnerability and anxiety with anger as a means of regaining a sense of power and control. Such anger

may be expressed in the form of confrontational and destructive behaviors including physical intimidation and violence, especially when individuals are affected by alcohol or other behavior-disinhibiting drugs.

There are also physiological differences associated with anger expression in men and women. Research has shown that for women, expressing anger is associated with a lowered heart-rate activity and more rapid blood-pressure recovery, whereas for men, expressing anger is associated with higher heart-rate activity and higher sustained blood pressure. Marital interaction researchers such as John Gottman and Patricia Noller have also demonstrated how, during marital arguments in laboratory settings, the most apparently stoic, nonangry men may show intense physiological stress reactions, as indicated by online measures of sweating, heart rate, and blood pressure. However, it is too simplistic to conclude from these findings that expressing anger is always helpful; it depends on how it is expressed and the opportunity such expression affords for a constructive outcome.

The Impact of Anger in Relationships

Relationships can be intrinsically frustrating, with partners not always able or willing to meet each other's needs, desires, and goals. Consequently, there is always the potential for anger when an individual's desires and goals are perceived to have been thwarted by his or her partner. As noted previously, angry individuals typically feel powerful and capable, and such perceptions may sometimes motivate energetic and successful attempts to resolve relational problems. At other times, however, anger may interfere with constructive problem-solving behaviors. In particular, both husbands and wives have been found to react more negatively to explicitly angry messages than to messages that communicate hurt or distress. Blaming, accusatory messages tend to be reciprocated in escalating cycles of negativity that become difficult to escape. Further, researchers have demonstrated that, once the attention of angry individuals is focused on perceived obstructions, they tend to become less trusting of their relationship partners and less likely to cooperate with them. Thus, the frequent experience and/or expression

of anger in relationships may have a corrosive effect over time, with angry partners perceiving each other through blood-shot spectacles and appraising each other's behaviors as automatically blameworthy and maliciously motivated. In support of this pattern, researchers have found strong negative associations between the overall frequency of angry displays by either or both partners and the marital satisfaction and stability.

There are also important individual differences with respect to so-called anger-proneness, a personality trait that has a negative impact on relationship functioning. In particular, researchers have identified individuals with chronically angry dispositions (also referred to as high trait anger) who are ever vigilant for offense and apparent injustice. Such individuals have a short fuse and tend to assume whenever anything unwanted occurs that someone (e.g., a partner or family member) must be to blame. To an extent, anger-proneness is similar to the hostility component of the type-A personality, whereby individuals hold general attitudes of dislike, cynicism, and contempt for others. However, anger-prone individuals do not necessarily dislike others. Rather, they perceive the world and others in narrow terms of 'right' and 'wrong' and respond to any undesired situation with appraisals of other-blame and expressions of anger. Such chronically angry individuals generate a relational climate of fear and loathing with anger, or the threat of it, serving to intimidate and control relationship partners. Further, strong associations between anger-proneness and the likelihood of physical violence toward intimate partners have been found, with some of the angriest and most physically violent men, in particular, suffering from fears of abandonment and/or loss of control.

These findings do not imply, however, that anger has no place in happy and successful long-term relationships. In fact, longitudinal research has demonstrated that like unhappy spouses, happy spouses still express anger to each other, but they also (and more frequently) express love, affection, and good humor. Further, happy spouses appear to understand that anger is a signal of unmet or thwarted needs and expectations; hence, they are more likely to inhibit their impulses to react defensively when their spouses express anger and to

respond instead in a conciliatory or constructive manner.

Finally, it should be noted that the basic theme underpinning almost all episodes of anger is the perception that someone has behaved in a way that violates individuals' expectations of how others (e.g., family members, spouses, friends, work colleagues) should behave. This perception implies that an effective way to regulate anger is for individuals to become aware of and to modify their expectations so that others' behaviors are less likely to be perceived as deliberately obstructive and their dispositions as intrinsically blameworthy. Research confirms that such reappraisals are effective in moderating feelings of anger and in encouraging constructive problem-solving responses to relationship difficulties, as is a healthy sense of humor to help put an individual's needs and desires into a wider perspective.

Conclusions

Evolutionary theorists have noted that there are times when anger is an appropriate and functional emotion. Indeed, the Greek philosopher Aristotle argued that only fools were never angry and that the absence of anger against just causes was a vice, not a virtue. In this sense, anger signals caring and commitment as opposed to apathy, and can be a healthy and natural feature of human relationships. However, research on psychological and relational well-being also suggests that people fare best when they can control the experience and expression of this powerful emotion, rather than be controlled by it.

APOLOGIES

Apologies express remorse for transgressions or social failures. A secondary meaning, associated with the Greek term *apologia*, is the offering of a justification or the defense of honor. The related term, *apologetics*, refers to a sustained defense of this type, as in the case of *Christian apologetics*. Apology remains an active area of study for researchers interested in the repair of broken relationships, relational justice, and the management of identity. The use of apology is linked to important and diverse social outcomes, such as the granting of forgiveness in marriage, judgments of guilt in court proceedings, and the success of public figures in restoring their reputations after

committing unethical or embarrassing acts. After reviewing historical and contemporary uses of the term, this entry considers three major traditions of apology research, measurement approaches, and emerging issues of concern.

Historical Perspectives

Apology is one of the oldest and most scrutinized of speech acts. It first received extended attention in the writings of Plato and Aristotle, who analyzed the defense offered by Socrates to his accusers. *Apologia* is a defensive discourse, a carefully crafted public statement through which the accused explain their motives and request exoneration. The audience for such statements includes not only the accusers but also a larger citizenry assumed to be acting as judges of the speaker's character.

Later, in the medieval period, the church became the audience and judge of these public apologies. The expected form of an apology resembled that of a confession—admitting one's mistakes before God. Apologies were crafted to seek God's forgiveness and, perhaps, intervention on behalf of the accused. As rhetorician Sharon Downey notes in her historical review, in the 19th century apology evolved to be a rebellious form of speech. The accused admitted guilt while also claiming that the guilty deeds were justified by a higher moral standard. As used by speakers like the American abolitionist John Brown, this brand of apology allowed the offender to play the role of scapegoat while inciting indignant audiences to further the speaker's objectives.

In recent decades, *apologia* has evolved further, often serving as an image restoration strategy for disgraced public figures and institutions. In such cases, the accused party cultivates audience identification with statements such as "We all make mistakes" and sympathy by casting doubt on the motives of the accusers. This form of apology minimizes the speaker's responsibility for the act while increasing the chances of political survival.

Social Science Perspectives

Contemporary writing on apology, including that of most social scientists, focuses on its role as an

expression of remorse for relational transgressions or social failures. The literature is complicated by its sometimes interchangeable use of related, but slightly different, terms. *Remorse* is a feeling of distress, sadness, or sorrow over one's actions. *Contrition* is a related term, often defined as the showing of sorrow or grief over one's behavior and its negative consequences. *Regret* is a painful feeling of disappointment with past behavior, often accompanied by a wish that the act had not occurred. *Repentance* is a future-oriented commitment to "turn away from sin." Regret and/or repentance are frequently included in apologies. They communicate a recognition of moral failure. Apologies are often considered a kind of *account*. Accounts provide an explanation for behavior that violates social expectation.

Research on apology has been conducted in three broad traditions that differ primarily in terms of relational context. The impression management tradition focuses on the ordinary interaction of strangers and acquaintances. A second relationship repair tradition is mostly concerned with the role of apology in redressing transgressions in personal relationships. Finally, the relational justice tradition concerns itself with institutionally mediated relationships, including those found in courtrooms and restorative justice systems.

Apology as Impression Management

Since at least the 1950s, apology has been conceptualized as a form of identity management. This approach has largely developed from the pioneering work of sociologist Erving Goffman, who studied how social actors negotiate the maze of social rules that regulates everyday interaction. According to Goffman's dramaturgical approach, social interaction is a kind of stage performance in which the actors must recognize the scene, enact the appropriate lines, and coordinate with the other actors to pull off a convincing performance. *Face* is Goffman's term for the identity derived and sustained by successful social performances, or *facework*. Apology is a strategy actors use when face is threatened by a failure to conform with social expectations that define a social situation. It is a means of addressing the embarrassment and emotional distress experienced by actors caught in such situations.

Preemptive apologies are used when a violation of expectation is anticipated. For example, the statement, "I am sorry to ask you such a personal question, but . . ." signals that the speaker is aware of rules against social intrusion and distressed by placing the listener in an awkward position. The apology compensates for looming face threat. It creates the impression of social competence and shows respect for the rules of interaction. Other times, apologies are offered after a face threat as a kind of compensation. After accidentally spilling a drink on another attendee, the visitor to a cocktail party typically offers an elaborate apology, replete with expressions of remorse and sometimes self-flagellation ("I am so, so sorry. How clumsy of me. How embarrassing!"). Apologies assure the audience that the victim is not at fault and restores respect through a display of deference.

False or insincere apologies play different roles in identity management. A false apology may be offered under duress (as when a parent orders siblings to apologize). When an apology is deliberately insincere, it may signal contempt for the recipient or a rejection of social conventions. To determine the sincerity of an apology, recipients and observers assess the degree of remorse it exhibits, often by examining tone of voice, facial expressions, and other nonverbal cues. Of course, minor infractions may require the mildest of apologies, as they simply acknowledge the rules of polite interaction. A quick "sorry!" is all that is needed when pedestrians collide on a crowded sidewalk. In such cases, a lack of intentional harm makes elaborate apology unnecessary.

Apology as Relationship Repair

Children learn early in life that an apology is the appropriate response to violations of the rules that govern family relationships. Indeed, the ability to recognize the social conditions that call for an apology is an important skill in close personal relationships. Apologies acknowledge the relational rights of family members, affirm relational rules, and increase certainty that transgressions will not reoccur. In marital relationships, the offering of a full apology increases the chance that the victimized partner will be forgiving. Full apologies acknowledge harm or wrongdoing, communicate remorse, and pledge improved

behavior, and sometimes offer compensation ("I will make it up to you. I promise"). Clinicians report some success when these elements are incorporated in therapies used to help distressed family members recover from serious transgressions. Full apologies are more likely to facilitate relationship repair than are excuses, denials, or justifications.

Research on close relationships indicates that severity of the transgression is an important consideration for offended partners. Severe transgressions require more elaborated apologies. Yet for some romantic partners, certain kinds of transgressions (e.g., sexual infidelity) are considered unforgivable. In such cases, apology may be expected and offered, but it may be insufficient to promote reconciliation. Forgiveness researchers have argued that sincere apologies may be valuable in fostering the mental health benefits that accompany forgiveness, even when victimized partners choose not to reconcile with the offending party.

Apology and Justice

Apology is linked in several ways to informal and formal systems of justice. For example, research on account-making examines the kinds of explanations offenders offer for violating laws, including traffic violations. In contrast to denials or justifications, researchers classify apologies as a type of concession—an admission of guilt. Evaluators, including courtroom judges, expect violators to apologize for transgressions and may be more lenient when apologies appear sincere. Apologies combined with convincing excuses ("I take full responsibility, but I was speeding to get my pregnant wife to the hospital") may be rated most favorably.

Restorative justice procedures supplement the punishments administered in traditional justice systems. Although procedures vary, most involve some kind of informal communication between victim and offender. A central feature of these programs is the opportunity for the victim to receive an apology. Although research is still developing in this area, advocates claim that the offender's apology empowers the victim and potentially reduces feelings of fear or bitterness. Critics are wary of these benefits, particularly for victims of certain

kinds of crimes, such as domestic violence. Repeated but insincere apologies are typical of abusers. Exposing victims to apologies in restorative justice programs potentially perpetuates the cycle of abusive communication.

Research Approaches

Researchers study apologies using several methodologies. Discourse analytic techniques examine the forms of verbal and nonverbal communication used to enact apologies. These researchers typically collect audio or video samples of naturally occurring apologies in settings such as courtrooms, therapy sessions, daycare centers, or press conferences. The data are sometimes converted to written transcripts. Analysts describe the organizational structure, content, style, and apparent functions of apologies, looking for (as examples) the nonverbal cues that signal sincerity or the language used to express remorse. The interpretations and evaluations of apology recipients and observers are often used to assess the meanings of apologetic discourse.

Apologies often occur in private, making direct observation impossible or unethical. As a case in point, spousal apologies for acts of marital infidelity are typically not available for direct observation. In these instances, researchers collect self-report data, including retrospective accounts ("Please describe a time when you delivered an apology to your spouse") or responses to hypothetical scenarios ("How would you respond if your spouse said this . . . ?"). In well-developed areas of research, participants complete psychometrically validated measures of relational repair behaviors, including apologies. Surveys of account-making or forgiveness-seeking communication ask participants to rate various types of apologies on Likert-type scales measuring likelihood-of-use or perceived effectiveness.

Emerging Research Concerns

Apology has been an object of systematic study for several thousand years. However, research is expanding in at least four areas. The role of apology in the healing of damaged relationship continues to interest clinicians and relationship researchers. This is most obvious in the growing

literature on forgiveness in personal relationships. In the public realm, the use of apology by public figures (e.g., President Bill Clinton), organizations (e.g., the Catholic Church), and even nations (i.e., Australia's apology to aboriginal peoples) continues to draw interest, particularly from scholars using the methods of critical discourse analysis. As mentioned above, research interest in the role of apology in restorative justice programs is growing. Finally, the role of gender in making and interpreting apologies is receiving attention. Researchers increasingly question how apologies are enacted differently by men and women and how these enactments sustain or resist gender stereotypes and power differences.

APPROACH AND AVOIDANCE ORIENTATIONS

To what extent do people try and enhance their close relationships or share many fun and meaningful experiences with their friends? To what extent do people try and stay away from situations that could harm their relationships or make sure nothing bad happens to their friendships? People have motivations or goals within their

social relationships that are derived from two separate systems: Motives focused on movement toward desired, positive relationship outcomes represent the *approach* system; motives focused on movement away from undesirable, negative relationship outcomes represent the *avoidance* system. This entry describes approach and avoidance orientations and reviews current work applying it to motivation in social relationships. It also discusses implications for how people think, feel, and act in relationships.

The approach and avoidance distinction has been a fundamental aspect of psychological theory and has been prevalent in many domains of research. For instance, Ivan Pavlov's early work on conditioning noted the existence of one reflex oriented toward the stimulus while another reflex was oriented away from the stimulus. More recently, Jeffrey Gray posited distinct approach and avoidance motivational systems, which he referred to as the Behavioral Activation System (BAS) and the Behavioral Inhibition System (BIS). BAS activates behavior in response to signals of reward and non-punishment, whereas BIS inhibits behavior in response to signals of punishment and nonreward.

There is also evidence to suggest these two motivational systems represent different underlying brain structures, providing a possible reason for its association with different emotions and behaviors. Specifically, the approach system is associated with more beneficial emotions and behaviors than the avoidance system. For example, BAS is associated with feelings of hope, and BIS is associated with feelings of anxiety. Other researchers have supported this BAS-positive emotions link by suggesting that the approach system is associated with a strong inclination to feel high positive emotions (elation, excitement) and low positive emotions (dull, sluggish). This research similarly supports a BIS-negative emotions link in that the avoidance system is associated with a strong inclination to feel high negative emotions (distress, fear) and low negative emotions (calm, relaxed).

Achievement motivation research has also distinguished approach focused motivation (performance-approach goals/need for achievement) from avoidance focused motivation (performance-avoidance goals/fear of failure). One motive is focused on the desire to outperform others and the feelings of pride that accompany that success,

while the other is focused on the desire to avoid doing worse than others and the feelings of shame that accompany such failure. Avoidance motivation has been shown to produce negative performance outcomes. Students who fear doing worse than others tend to have low self-efficacy, experience high anxiety, possess low interest in tasks, and earn low course grades. Approach motivation, by comparison, reliably predicts high achievement in the classroom.

Motivation in Social Relationships

Building on research in these other contexts, relationship researchers have incorporated the approach and avoidance distinction into their models of motivation. Approach social motivation is focused on movement toward positive outcomes, such as making social contacts and obtaining closeness. It is associated with establishing, maintaining, and restoring positive relationships with others and includes a hope for affiliation and intimacy. Researchers measure the strength of this motivation with items addressing such constructs as the frequency of social interactions and social functions, the association of positive emotions with social interactions, and the desire to be with friends and partners. For example, on a first date, a person who has strong approach social motivation may say, "I want to make a good impression."

Avoidance social motivation is focused on movement away from negative outcomes, such as avoiding being hurt and preventing conflict in relationships. It stems from feelings of insecurity and includes fear of and sensitivity to rejection. Researchers measure the strength of this motivation with items addressing such constructs as uneasiness with discussing controversial topics, sensitivity to criticism, fear of hurting others, and anxiously expecting and intensely reacting to rejection. For example, on a first date, a person who has strong avoidance social motivation may say, "I don't want to make a fool of myself."

Implications for How People Think, Feel, and Act in Relationships

Similar to emotion, achievement, and other domains, the approach system in relationships is

associated with better outcomes than the avoidance system. People with strong approach social motivation elicit more positive emotions from others, are less anxious and lonely, and feel more self-confident. They also experience greater relationship satisfaction and are more likely to maintain satisfying relationships over time. People with strong avoidance social motivation are more anxious and lonely, less self-confident, and are judged less positively by others. They also experience lower relationship commitment and greater rates of relationship dissolution.

During everyday life, people with high levels of approach social motivation tend to experience more positive events such as fun with friends and partners, pleasant conversations, and feelings of appreciation and support. This increased exposure to enjoyable interpersonal experiences is one reason why they may feel better about their relationships and maintain them longer. People with high levels of avoidance social motivation, in contrast, tend to react strongly to disagreements and conflict in their daily life, and this is one reason why they feel more anxious and dissatisfied about their relationships. Reactivity to social rejection has been a particular focus of research by Geraldine Downey. She and her colleagues examine one specific form of avoidance social motivation called *rejection sensitivity*, described as a tendency to anxiously expect rejection, readily perceive it, and overreact when it occurs. For people who have a high level of rejection sensitivity, an ambiguous social situation may be perceived as rejection. Rejection sensitivity is associated with negative behavior and hostility during problem solving discussions and increased negative emotions following conflicts with a romantic partner. For men, high rejection sensitivity has also been associated with increased incidents of violence in dating relationships. Downey and colleagues have also found that the partners of high rejection sensitive individuals may respond in ways that fulfill these rejection expectations. In other words, a self-fulfilling prophecy may occur such that partners actually behave more rejecting toward high rejection sensitive people.

Approach and avoidance motivation also influence the information used to judge life satisfaction and relationship satisfaction. People with strong approach motivation are more likely to base ratings

of daily life satisfaction on the positive emotions and social interactions experienced that day and similarly, base their relationship satisfaction evaluation on the positive emotions and interactions associated with their romantic partner. To someone who is mainly approach oriented, successful interactions and relationships are those that provide fun, companionship, and understanding; and painful relationships are those that fail to provide these rewards. In contrast, people with strong avoidance motivation base their satisfaction evaluations on the negative emotions and interactions felt that day. To someone who is primarily avoidantly motivated, pleasing interactions and relationships are defined as those that lack uncertainty, disagreements, and anxiety; painful relationships are those that possess these negative qualities.

There are other ways in which approach and avoidance motivation influence how people think about the social environment. People with strong avoidance social motivation are more likely to remember and interpret social information with a negative bias and to evaluate social situations more pessimistically. For example, participants were given a fictitious short essay describing a dating couple and their recent evening at a party. When asked to remember this story word for word, those with strong avoidance motivation were more likely to remember the negative events (e.g., the boyfriend did not introduce his girlfriend to other people at a party) and remember the positive events with a negative twist. Furthermore, this negative bias can be exacerbated depending on the social situation. In a separate study, participants were told they were going to meet a stranger and given either avoidance-oriented instructions (i.e., "Try not to make a bad impression) or approach-oriented instructions (i.e., "Try to make a good impression"). When people with strong avoidance social motivation were given the avoidance-oriented instructions, they remembered more negative information about the stranger and expressed more dislike for him or her.

Motivation in Sexual Relationships

Approach and avoidance motivation has also been applied to the context of sexual interactions. Approach sexual motivation includes having sex to increase intimacy with a partner and to enhance

physical pleasure. Avoidance sexual motivation includes having sex to prevent rejection by a partner or peers and relief from negative emotions such as loneliness. People with strong approach sexual motivation experience greater levels of positive emotions, well-being, sexual satisfaction, and relationship satisfaction. Perceiving a partner's sexual motivation as approach-oriented is also associated with better emotional and relationship well-being. In contrast, people with strong avoidance sexual motivation experience more negative emotions and relationship conflict, less relationship satisfaction, and a greater likelihood of relationship dissolution.

Approach social motivation has also shown to influence sexual desire in relationships. People with strong approach social motivation are more likely to engage in sex for approach-oriented reasons, and this helps to maintain sexual desire during the relationship. Furthermore, sexual desire tends to be higher on days with a greater number of positive relationship events (e.g., share enjoyable activities together, show affection) and lower on days with a greater number of negative relationship events (e.g., have arguments, feel criticized). People with strong approach social motivation capitalize on these good times and experience even stronger sexual desire on days with positive relationship events while not letting the days with negative events bring down their sexual desire.

Motivation for Sacrifice and Commitment

Another way approach and avoidance motivation affects relationships is through everyday relationship sacrifices (i.e., enacting a behavior that is not preferred such as accompanying a partner to a work function instead of spending time on an enjoyable hobby). On days people sacrifice for approach reasons (e.g., to promote intimacy), they tend to report more positive emotions and relationship satisfaction, whereas on days when they enact the same behaviors for avoidance reasons (e.g., to avoid conflict), they report more negative emotions, lower relationship satisfaction, and more conflict. Sacrificing for avoidance reasons is particularly detrimental to the maintenance of relationships over time. The more people sacrifice for avoidance

reasons, the less satisfied they are in their relationships and the more likely they are to break up.

Relationship commitment can also be understood from an approach-avoidance perspective. Specifically, people with strong approach commitment want to maintain their relationship for the incentives it can provide, such as fun, love, and companionship. People with strong avoidance commitment do not want the relationship to end because of the threats and costs associated with ending the relationship, such as loss of invested time and energy, having to start over in a new relationship, and the possibility of being alone. Studies in dating relationships have shown approach commitment is associated with high relationship satisfaction, whereas avoidance commitment is associated with low relationship satisfaction.

ARCHIVAL METHODS

Archival data can be inclusively defined as information that is stored in some identifiable location for some substantial period and to which researchers can obtain access so as to carry out an investigation on a subject unrelated to the original rationale for preserving the data. The information can assume almost any form, including newspapers, magazines, diaries, letters, reports, photographs, drawings, carvings, music, advertisements, or film clips. The data may have been saved for many different reasons. At one extreme are documents or artifacts that are quite deliberately saved as part of the historical record. Examples include acts of the U.S. Congress, patent applications, election results, crime figures, census data, sports statistics, issues of the *New York Times*, and restored classic films. At the other extreme are items of more ephemeral interest that may have been originally preserved more by accident than by design. Instances might include old high school yearbooks, private wartime correspondence, or amateur photographs of graffiti in public bathrooms. Although the researcher must have access to the archives to obtain the raw data, the access may vary in openness. Some archives require exclusive approval, such as the letters of a recently deceased celebrity or the film outtakes still stored in studio vaults, whereas others are open to the general public, such as the records kept by the Library of Congress or databases made available on the Internet.

This entry begins with an overview of the method and then turns to an evaluation of its usefulness in the scientific study of human relationships.

Methodology

An archival data analysis begins like most research in the behavioral sciences, namely with a hypothesis or at least conjecture about the way human beings behave in a given situation or set of situations. Yet

from that point, archival analyses must depart from such standard methods as the experiment, survey, or interview. This departure occurs because the raw data already exist, requiring that the investigator only determine the data's location and the optimal manner of exploiting the data retrieved. The next steps after data retrieval are also distinctive in comparison to more mainstream methods. In the first place, the investigator must decide on the most appropriate unit of analysis. Whereas for most research the unit would be the individual research participant, archival data analyses have more options. For instance, the units might consist of consecutive years of national divorce statistics, film clips depicting scenes in which two characters fall in love, or newspaper comics whose main characters are parents, friends, or coworkers. The choice of analytical unit will often represent a compromise between the hypothesis being tested and the data that are actually available.

The next step is to define the sampling criterion or criteria. Here again there are abundant choices. The units might be confined to specific years and to geographical locations. The units might be randomly selected from a larger sample or even taken to exhaust the population (e.g., all Pulitzer-winning novels). Once the sample is defined, the raw data must be collected and prepared for variable coding and statistical analysis. Although sometimes archival data are already in a form suitable for data analysis, more often they must be first subjected to a well-defined coding scheme, most commonly some form of content analysis. These coding procedures will include not just the substantive variables of interest but also any control variables needed to avoid methodological artifacts. Once this process is complete, the investigator can apply various statistical techniques, such as multiple regression, factor analysis, structural equation models, and time-series analysis. Because archival data studies are inherently correlational in nature, the statistical analyses will often have to be more sophisticated than in laboratory data over which the investigator can exert experimental control.

Evaluation

Archival methods are much less frequently used than more mainstream techniques. One reason for this infrequent use is that the data samples and

coding strategies may be less than ideal. Researchers using archival data must deal with the information that they can get rather than what they would like to have. At times, the data may contain methodological artifacts that may not be immediately apparent. From time to time a recently published archival study will inspire critiques by researchers who have managed to discern a source of spuriousness not immediately obvious to the original investigator.

These disadvantages do not suffice to invalidate the method. For one thing, potential artifacts can often be avoided by improved data collection and analysis procedures. In addition, archival methods can help establish when results obtained in the laboratory have genuine applicability to the practical world. Furthermore, unlike more commonplace approaches in which the data are most often collected within a single year, archival methods permit analyses of changes in human behaviors over long periods of time (e.g., historical trends in the average age at first marriage). But most significantly, researchers using archival methods have made important contributions to the scientific study of human relationships. Just in the area of intimate adult relations the substantive contributions include using (a) animal encyclopedias to decipher the evolutionary origins of adult pair bonding, (b) print and online singles advertisements to understand mate preferences in both heterosexual and homosexual couples, (c) wedding and divorce announcements in celebrity magazines to identify the factors underlying marriage longevity, (d) crime statistics and professional game schedules to assess the impact of viewing team sports on reported domestic violence, and (e) shelter admission interviews to discover the conditions that lead battered women to remain in abusive relationships.

The potential utility of archival methods has been reinforced by three recent developments. First, with the advent of the Internet, archival data have become much more diverse and at the same time much more accessible. Second, researchers are increasingly expected to archive their data sets, thereby making them available for future research, including investigations not directly related to those that motivated the original study. Third, advances in statistical techniques, such as multilevel modeling, greatly

expand the analytical power that can be applied to archival data.

ARGUING

Arguing (also called *quarrelling*, *verbal conflict*, and *interpersonal conflict*) is expressed disagreement. Because arguments can have negative consequences, some people try to avoid them; when arguing, they try to minimize the likelihood that their disagreement will escalate. Hence, relative to other types of conversations, arguments are infrequent, and argumentative episodes are often of very short duration. Arguing occurs among strangers, superiors and subordinates at work, colleagues, neighbors, roommates, friends, dating partners, and family members. Frequent interaction with another as well as increased interdependency stimulates arguing, and arguments typically are more frequent, prolonged, and intense with intimates than with nonintimates. This entry examines how arguing is conceptualized and measured, the causes and correlates of arguing, and the consequences associated with arguing.

Conceptualization and Measurement

Arguing is a form of interaction as well as a form of conflict and can be distinguished from other forms. Relative to nonargumentative interactions, people report that arguments are more likely to involve disagreement, criticism, sarcasm, and

insults that are loudly expressed. Not surprisingly, individuals frequently use negative metaphors (e.g., being in a war) to describe their arguments. Conflict is the existence of incompatible activity, and expressed disagreement falls under that rubric. Although arguing is a form of conflict, not all conflicts become arguments. Some incompatible activity is not discussed, and there is no argument. In such cases, there can be mutual awareness of conflict in the absence of arguing (e.g., discussing the conflict topic is declared taboo), and conflict may be manifested in different forms than arguing (e.g., the silent treatment, denial of support).

Arguments are episodic (i.e., composed of a connected set of events). They are initiated when a person perceives a provoking action and challenges the provocateur who responds by resisting. Arguments are typically focused on a given issue (e.g., money), but they can expand to include others (e.g., “You are a spendthrift”) and may include a hidden agenda (e.g., “You don’t respect me because you never ask my opinion”). During an argument, individuals can pressure the other person to change, disclose feelings, generate solutions, repair the relationship, minimize the disagreement, and withdraw from the interaction. Some behaviors occur in sequences, such as demand and withdraw (i.e., one partner demands and the other withdraws), escalating reciprocity of negative affect and mutual complaining. Because arguments frequently end with no resolution, episodes may be repeated and become serial arguments. Between episodes, individuals often mull about what was said and what they will say in the next one. Over time, serial arguments can become scripted in that each partner plays a given role (e.g., initiator or target); partners can predict when an episode will occur and anticipate what each will say.

Researchers study both the general characteristics of arguing and the features of specific argumentative episodes; the measures vary with the focus of the research. When examining the general characteristics of arguing, respondents are typically asked to self-report (either on questionnaires or in diaries) the degree to which their everyday arguments can be characterized as frequent, stable, intense, predictable, constructive or destructive, emotional, or resolved. Such measures provide a summary of what individuals perceive that most of their arguments are like, but these measures may not provide

a fine-tuned assessment of the behaviors that are perceived to be enacted within an argumentative episode. To gain insight into episodic behaviors, researchers rely upon self-reports about what occurred in a specific encounter (e.g., one that occurred on a given day or that occurred most recently). Respondents report the degree to which their argument focused on particular issues, how long the episode lasted, how long ago the episode occurred, the conditions that prompted the argument, who initiated the argument, the behaviors or behavioral sequences that their partners enacted, and the outcome of the episode.

Because self-reports can be inaccurate, researchers rely upon behavioral observations to assess arguments. When doing so, they often ask relational partners to reenact a prior argument, engage in a simulated argument, or discuss an upcoming issue that could lead to an argument. Interactions are taped, and the actions are categorized or rated by trained coders. In some cases, the partners are shown the tape of their interactions and asked to code the behavior or to describe what they were thinking at a given point. This approach allows research to compare an individual’s response with that of his or her partner and with trained coders. Although providing a rich source of data about argument, behavioral observations are labor intensive. Researchers must convince relational partners to participate in a taped argument, find appropriate contexts (e.g., a laboratory, the home) in which to observe the episode, choose an appropriate stimulus for the argument, select the appropriate verbal and nonverbal stimuli to code or rate, develop coding categories that are valid indicators, train coders to make reliable judgments, and control for a variety of factors that adversely influence the statistical analysis (e.g., skewed distributions, nonindependent observations).

Causes and Correlates

Individuals report that they argue about a variety of issues including money, social issues, personal habits, sex, communication, and power. Underlying these issues is the notion that arguing arises from violated expectations. Something about the state of the relationship and/or a partner is perceived to be at variance with appropriate standards (e.g.,

etiquette, morality, conventionality, role expectations, well-being, and consistency). However, individuals may perceive such violations and never confront a partner about them or, if confronted, may comply and thereby avoid an argument. Hence, certain conditions must be present to stimulate arguing. A variety of factors increase the willingness to argue, including (a) relational intimacy, (b) perceiving that another's actions are disrespectful, (c) confidence that one knows how to argue, (d) the urgency of the situation, (e) having a legitimate right to argue, (f) enjoying arguing, (g) perceiving that arguing will enhance relational quality, and (h) concern for the partner's well-being.

The manner in which one acts during an argument results from a number of factors. Some individuals have a conflict style or set of beliefs about conflict that predisposes them to argue in a particular way. Individuals who believe that disagreement is personally and relationally destructive avoid confrontations, while individuals who enjoy arguing confront others. Verbally aggressive individuals use competency and character attacks to influence others, while argumentative individuals rely on logic. The perceptions and emotions associated with an argument may also influence a person's actions. The degree to which individuals blame their partners for a problem or are angry with them can stimulate destructive actions. When in an argument, individuals often influence each other's actions. In many instances, individuals reciprocate each others behaviors (e.g., complaints lead to countercomplaining), but in other instances, complementary patterns are observed (e.g., complaints lead to apologies). Finally, the presence of observers can influence argumentative behaviors by signalling approval or disapproval of certain actions.

Skills associated with approaching conflict in a competent fashion include perspective taking, using polite and sensitive language, engaging in emotional control (e.g., impulse control, self-soothing), asking questions, being responsive to the partner's statements, summarizing and paraphrasing, taking time-outs, and developing solutions. Skill enactment results from knowledge (i.e., understanding what one should do during an argument), outcome efficacy (i.e., believing the skills will be successful), and self-efficacy (i.e., feeling that one has mastered the skills).

Consequences

The most obvious consequence of arguing is whether or not the issue was resolved. Although surprisingly little research has directly assessed resolution, arguments most frequently end in a standoff or with one or both parties withdrawing from the interaction. Apologies and compromises are less common outcomes. Furthermore, some arguments end with a pseudo-agreement in which one party submits to the partner's desires simply to stop the argument and therefore has little commitment to the agreement.

In part, the ability to resolve an argument stems from the manner in which the confrontation begins. In some cases, individuals confront their partners in a highly emotional way that creates emotional flooding followed by reciprocated emotion or withdrawal. Or individuals may begin the confrontation in a way that is perceived to be a face attack (e.g., a criticism or insult) that prompts partners to become defensive as they try to restore their image. In both cases, partners stand their ground or may even adopt increasing divergent positions as the argument progresses, a situation that makes resolution unlikely.

Arguing also has consequences for relationships. In general, the frequency of arguing is negatively related to relational satisfaction and positively related to the likelihood of relational dissolution. Indeed, the frequency of arguing about relatively minor issues is negatively related to relational satisfaction. Relational difficulties arising from arguing may stem from several processes. First, frequent arguing may give rise to negative actions such as insults and physical aggression. Second, frequent arguing may cause individuals to believe that a conflict is irresolvable and will remain a part of their relationship. Third, frequent arguing could have a negative impact on others who are related to the partners such as family and friends.

The point at which arguing becomes damaging to a relationship may vary. Some couples thrive because of their willingness to argue and their view of disagreements as a sign of vitality and relational commitment, whereas other couples find even infrequent arguing to be unpleasant and threatening. The key seems to be the beliefs partners hold about arguing as well as their ability to repair any damage resulting from their disagreements. If

couples view arguing as positive, believe they are making progress toward resolution, avoid enacting destructive argumentative patterns (e.g., mutual attacks), and reinvest in their relationship after an argument, there may be less relational harm and possibly even relational enhancement. However, constructive conflict behaviors such as active listening and empathy do not always protect a relationship from damage. Indeed, the negative effect of destructive conflict behaviors is greater than the positive effect of constructive actions.

Arguing can also affect personal well-being. Some individuals are emotionally drained, depressed, and stressed after an argument. These outcomes can adversely influence their physical and psychological health as well as their ability to perform in other areas of their life (e.g., at work), and these effects can extend over several days after an argument. Such consequences are especially likely when arguments are frequent and are perceived to be irresolvable. However, not all individuals find arguing to be punitive. Argumentative individuals are very good at reasoning, enjoy arguments, seek out disagreements, and regret having missed the opportunity to argue with another. Moreover, some individuals engage in personal coping tactics that seem to alleviate the negative states often resulting from arguing.

Although arguing is not universally harmful, many distressed couples seek therapy to control excessive and destructive conflict. Couples therapists can utilize behavioral approaches that train individuals to reciprocate positive actions and to engage in problem-solving communication. This approach is sometimes combined with a cognitive component aimed at reducing negative attributions for relational problems and increasing perspective taking and/or therapies aimed at increasing acceptance of irresolvable issues. The aforementioned approaches have positive short-term impact on marital quality and may have longer term benefits for particular types of couples.

ARISTOTLE AND PLATO ON RELATIONSHIPS

The eminent 20th-century philosopher Alfred North Whitehead is reported to have said, “All of Western philosophy is but a footnote to Plato—and Aristotle wrote most of the footnote.” Indeed, the seminal contributions of Plato and Aristotle, writing in Athens 2,500 years ago, are foundational for

nearly all Western scholarship, including the various social science approaches to understanding human relationships.

Plato's writings are in the form of dialogues centered around his teacher, Socrates, so that it is impossible today to sort out which ideas are Socrates' and which are Plato's. Aristotle was Plato's student. Plato's greatest direct influence relevant to relationships is his work on love, mainly in the *Symposium*. Aristotle's greatest directly relevant influence is on friendship, mainly in his systematic treatise, the *Nicomachean Ethics*.

This entry briefly summarizes Plato's work on love and Aristotle's on friendship, noting links of each with contemporary social science work on relationships.

Plato on Love

The *Symposium* (a drinking party) is a series of toasts or speeches praising love. The initial speeches describe various understandings of love, ranging from love as sexuality, love as the search for one's soul mate, to love as the highest virtue. Socrates, the honored guest, speaks last, supposedly quoting the mystic Diotima of Mantinea, "a woman wise in this and in many other kinds of knowledge":

Love may be described generally as the love of the everlasting possession of the good.

All animals . . . , in their desire of procreation, are in agony when they take the infection of love, which begins with the desire of union; whereto is added the care of offspring, on whose behalf the weakest are ready to battle against the strongest even to the uttermost . . . the mortal nature is seeking as far as is possible to be everlasting and immortal.

[Then] think of the ambition of men, and . . . consider how they are stirred by the love of an immortality of fame. They are ready to run all risks greater far than they would have for their children, and to spend money and undergo any sort of toil, and even to die, for the sake of leaving behind them a name which shall be eternal. . . .

These are the lesser mysteries of love. . . . For he who would proceed aright in this matter should begin in youth to visit beautiful forms; and first, . . . to love one such form only . . . and soon perceive that the beauty of one form is akin to the beauty of another; and then . . . recognize that the beauty in every form is and the same . . . and become a lover of all beautiful forms. [I]n the next stage, consider that the beauty of the mind is more honourable than the beauty of the outward form. . . . until he is compelled to contemplate and see the beauty of institutions and laws, and to understand that the beauty of them all is of one family, and that personal beauty is a trifle; and after laws and institutions go on to the sciences, . . . create many fair and noble thoughts and notions in boundless love of wisdom; until at last the vision is revealed of a single science, which is the science of beauty everywhere. . . . toward the end he will suddenly perceive a nature of wondrous beauty—a nature which in the first place is everlasting, not growing and decaying, or waxing and waning. . . .

Summarizing all this, Socrates' Diotima concludes with "the true order of love":

[B]egin from the beauties of earth and mount upwards for the sake of that other beauty, using these as steps only . . . from fair forms to fair practices, and from fair practices to fair notions, until from fair notions one arrives at the notion of absolute beauty, and at last knows what the essence of beauty is. . . . Would that be an ignoble life?

In terms of direct contemporary influences, the initial speeches are reflected in sociologist John Alan Lee's taxonomy of love styles and the widely used questionnaire based on it developed by Clyde and Susan Hendrick. Socrates' speech is reflected in Arthur and Elaine N. Aron's self-expansion model emphasizing love as a motivation for the person to expand the self toward greater and greater goals.

As an aside, in common modern usage *platonic* refers to a nonsexual relationship. This is largely a misunderstanding of Plato, who saw sexuality as a central part of love, at least in its less-exalted stages.

Aristotle on Friendship

For Aristotle, friendship is based on the reciprocation of affection between individuals, with this type of emotional bond forming the basis for various levels of social organization, whether personal or institutional. Aristotle considers friendship necessary for achieving the “good life” in which one will be most happy. This is because devotion to another creates opportunities to do generous and virtuous deeds, which develops moral character. This view is reflected in modern thinking most prominently in the role of friendships in children’s development of social skills and values.

Aristotle also holds that central to friendship is fairness and sympathetic interest, characteristics he believes are present in a good person’s relationship with the person’s inner, true self. In *Nicomachean Ethics*, he states, “To perceive a friend, therefore, is necessarily in a manner to perceive oneself, and to know a friend is in a manner to know oneself”; friends are “other selves”; friendship is “one soul abiding in two bodies.” These ideas are reflected in the contemporary self-expansion model work on inclusion of other in self in which those in a close relationship spontaneously think and act to some extent as if each also contained the other’s resources, perspectives, and identities.

A particularly influential aspect of Aristotle’s views is that there are three main forms of friendship: one based on usefulness or utility, one based on enjoyment, and one based on the good or pure virtue. The last refers to relationships where partners seek to benefit each other for the other’s sake rather than for the benefit to the self alone. This three-part view has been a basis for some modern taxonomies of friendship and is most prominently reflected in Margaret Clark and Judson Mills’s influential distinction between exchange relationships (where each is expected to provide benefits to the other—thus reflecting Aristotle’s utility and enjoyment) and communal relationships (where each attends to the other’s needs—thus reflecting Aristotle’s notion of virtue).

AROUSAL AND ATTRACTION

Many of the entries in this encyclopedia refer to specific human relationships concepts (e.g., loneliness, unconditional positive regard). In contrast, this entry reviews the influence of one concept, *arousal*, on another, *attraction*. This association merits its own entry for several reasons. The influence of arousal on attraction has been examined directly by psychologists for over 30 years. During that time, researchers have offered multiple theories to explain the link between arousal and attraction or have questioned whether arousal influences attraction at all. The association between arousal and attraction is important because it provides valuable information about romantic attraction and romantic relationship development. The association between arousal and attraction also provides a specific testing ground for broader theories of human behavior.

To understand the influence of arousal on attraction, one should first clarify the concepts of arousal and attraction. In this context, arousal refers to the experience of being in a physiologically aroused state. The exact nature of such arousal might be difficult to define precisely, but measures of physiological arousal include increased heart rate, increased blood pressure, and increased sweating. Researchers also measure physiological arousal by simply asking participants whether they feel physiologically aroused or alert. These measures are consistent with activation of the sympathetic

nervous system. The sympathetic nervous system prepares the body for action, whereas its counterpart, the parasympathetic nervous system, slows the body's functioning to allow energy conservation and recovery. Research examining arousal and attraction has incorporated a variety of methods to induce arousal, such as having participants experience fear, engage in exercise, or view sexually stimulating material.

Attraction (often called interpersonal attraction) refers to the process by which individuals form positive attitudes toward others and seek to interact with others more closely. This general concept includes more specific forms of attraction. For example, the arousal and attraction effect is most closely tied to *romantic attraction*—a desire to develop a nonplatonic relationship with another person. Similarly, arousal and attraction research has often required participants to rate another's *physical attractiveness*. Perceived physical attractiveness is clearly intertwined with romantic attraction, although individuals could conceivably evaluate others as more or less physically attractive without altering their interest in forming corresponding romantic relationships. The influence of arousal on attraction has also been examined using *liking* as an outcome.

The Arousal and Attraction Experiment

The traditional arousal and attraction experiment has two primary components. First, participants are randomly assigned to an arousal condition or to a control condition (sometimes these conditions are labeled high-arousal and low-arousal). Second, after arousal is induced (or not induced), researchers measure attraction by having participants respond to questions or engage in a situation in which they can demonstrate attraction behaviorally. To illustrate, researchers might tell participants in the arousal condition that the experimental procedure includes painful electric shocks but tell participants in the control condition that the procedure includes a less-threatening stimulus such as the sound of a typewriter. Following this manipulation, all participants respond to questions about how much they would like to date a particular individual (i.e., the target) or see the individual on another occasion. The target individual is often an attractive person of

the opposite sex (i.e., men respond about women, and women respond about men). The experiment then concludes, and none of the participants actually receive electric shocks.

Using this traditional paradigm, research generally shows that aroused individuals indicate more attraction toward attractive opposite-sex persons than do nonaroused individuals. The size and reliability of this effect is difficult to determine precisely, as the influence of arousal on attraction varies in different experimental settings. Notice also that arousal and attraction research has generally relied on the practical assumption that the vast majority of participants are heterosexual; presumably, aroused homosexual participants would respond to same-sex persons much like heterosexual participants respond to opposite-sex persons.

Arousal and Attraction Theories

Researchers have offered three primary theories to explain why arousal influences attraction. First, according to misattribution theory, arousal from one source is mistakenly attributed to another source—in this case, the target individual. For example, individuals who are aroused by the anticipation of electric shocks mistakenly attribute that arousal to the presence of an attractive opposite-sex person and therefore experience greater levels of attraction. Second, according to negative-reinforcement theory, participants find the target to be reinforcing because the presence of another person reduces unpleasant fear-based anxiety. This negative-reinforcement causes participants to experience increased attraction to the target. Third, according to response-facilitation theory, romantic attraction is the dominant, or prevailing, response when most individuals encounter an attractive opposite-sex person. Because arousal increases the likelihood of the dominant response, aroused participants experience enhanced levels of attraction toward attractive opposite-sex persons. Each of these theories can plausibly explain why fear-based arousal increases attraction toward attractive opposite-sex persons. Yet the basic arousal and attraction paradigm has been implemented in several ways, and these methodological variations have important implications.

First, arousal appears to influence attraction even when the source of the arousal is not

ambiguous. To illustrate, when participants assess their romantic attraction shortly after exercising, they likely recognize the exercise as the true source of their arousal. This finding appears inconsistent with misattribution theory, which suggests that individuals will misattribute arousal only when its true source is ambiguous.

Second, arousal influences attraction regardless of whether the arousal was generated by fear, exercise, or sexually explicit material. This finding appears inconsistent with negative-reinforcement theory, which is based on the reduction of unpleasant fear-based arousal.

Third, arousal has a polarizing effect on attraction. Arousal enhances attraction toward attractive opposite-sex persons, but it reduces attraction toward unattractive opposite-sex persons; arousal appears to have minimal influence on attraction toward opposite-sex persons of average attractiveness. This polarizing effect is inconsistent with negative-reinforcement theory because there is no compelling reason to believe that fearful individuals would find the presence of an attractive opposite-sex person to be reinforcing but the presence of an unattractive opposite-sex person to be punishing. The polarizing effect of arousal on attraction is also awkward for misattribution theory because individuals probably do not perceive their arousal as being generated by the unattractiveness of an opposite-sex person. Response-facilitation theory can account for the polarizing influence of arousal on attraction if aversion is a common dominant response toward unattractive opposite-sex persons.

Fourth, the influence of arousal on same-sex versus opposite-sex attraction is less clear, but there is some evidence to suggest that arousal has a stronger influence on attraction toward opposite-sex persons than it does toward same-sex persons. Examinations into the influence of arousal on same-sex versus opposite-sex attraction have focused primarily on liking rather than on romantic attraction or perceived physical attractiveness. Results demonstrating that arousal influences liking for opposite-sex persons more than same-sex persons are troublesome for negative-reinforcement theory, which does not suggest directly that opposite-sex persons reduce fear-based arousal more than same-sex persons do. Response-facilitation theory could account for this finding if liking is more frequently a

dominant response for opposite-sex persons than it is for same-sex persons.

Based on these findings, response-facilitation theory appears to have the best potential to explain the influence of arousal on attraction, but this theory still suffers from a lack of clarity about dominant responses. Conceptions of the dominant response have traditionally focused on behavior (e.g., actually asking a person to go on a date), but most arousal and attraction experiments measure evaluation (e.g., reporting that the target is attractive). Some research has associated dominant-response theory with cognitive processes like evaluation, but the singular use of dominant-response theory to explain how arousal influences attraction is potentially complicated. For example, even if individuals commonly experience romantic attraction toward attractive opposite-sex persons emotionally, they might not typically engage in behaviors that demonstrate romantic attraction. In fact, individuals commonly avoid approaching attractive opposite-sex persons, particularly when such individuals are shy or romantically involved. Accordingly, it seems unclear currently as to which dominant responses would be triggered in different situational contexts.

A more recent interpretation of arousal and attraction has attempted to integrate the deliberate social-cognitive process suggested by misattribution theory and the more unintentional process suggested by response-facilitation theory. The influence of arousal on attraction might be explained by a judgment and adjustment model. This model proposes that individuals evaluate their attraction towards others automatically. Accordingly, individuals evaluate attraction before they can account for situational factors like the original source of arousal. Recent research has supported the perspective that many social-cognitive processes occur efficiently and without noteworthy levels of individual awareness, intention, or control. Similarly, arousal might be integrated automatically into evaluations of attraction, thereby making attractive opposite-sex persons more attractive and unattractive opposite-sex persons less attractive. Following this automatic process, individuals can control their evaluations and adjust for situational factors. Thus, individuals can adjust their estimates of romantic attraction when they believe that the situation influenced their initial judgments. Because individuals often underestimate or fail to recognize

the influence of arousal, this adjustment reduces but does not eliminate the average influence of arousal on attraction. A handful of experiments have attempted to manipulate the degree to which aroused participants were aware of their original source of arousal, either by making the original source of arousal salient or by distracting participants with a cognitive task (e.g., remembering a seven-digit number without writing it down). Results are potentially consistent with the concept of adjustment; awareness of the original source of arousal seems to reduce the influence of arousal on attraction.

Conclusion

The influence of arousal on attraction is important to scholars because it provides insight into interpersonal attraction and more general emotional and cognitive processes. However, the lay person who is equipped with an awareness of arousal and attraction could attempt to apply this knowledge to his or her advantage. Attractive individuals might be able to enhance their attractiveness by making use of environments that elicit physiological arousal. For example, an attractive individual might appear more attractive to those exercising in a gym or to others on exhilarating amusement park rides. In fact, it seems that some individuals have been using the arousal and attraction effect by taking dates to horror movies in hopes that the arousal generated by a frightening film might enhance romantic excitement. Indeed, so long as there is existing chemistry, providing a potential partner with a plethora of cappuccinos might contribute to an interpersonal love potion.

ARRANGED MARRIAGES

Young children in the United States taunt one another about cross-sex friendships by chanting “First comes love, then comes marriage. . . .” This chant reflects a common assumption in the Western industrialized world, as well as elsewhere, about how one enters into a marital relationship—via the process of developing an intimate, romantic relationship with another person and subsequently choosing to formalize a commitment via marriage. In arranged marriages, the people getting married may not know one another prior to their wedding day, and the decisions that resulted in their marriage were made at least in part by other people—their family and community. By some estimates, 80 percent of documented cultures in the world engage in some form of arranged marriage practice. Even in the industrialized West, arranged marriages occurred in the past, and certain subgroups, such as Hindu individuals living in the United States and Canada, continue to arrange marriages in the present time.

Variation in Marital Arranging Practices

The variety of ways in which arrangements for marriage are made across and within cultures is enormous. This variety is made even more complex because cultural practices for arranging marriage are not static—they change over historical time. The exporting of Western concepts like that of love marriage, as represented in films and popular culture, also alters the practices that people in different places engage in and the ways they talk about their relationships.

Some of the variability in practices revolves around who is eligible to be married. For example, cultures and subcultures vary in whether arrangements involve prepubescent children, who may live apart until they reach a marriageable age, whether the age of eligibility for marriage is the same for males and females, and whether first cousins are viewed as appropriate or desirable

marriage partners (termed *consanguineal marriage*). Practices may involve the exchange of gifts or money, in some cases money that comes with the bride (also termed *dowry* or *bride wealth*), and in some cases, money or resources that the groom's family pays as a kind of exchange for the wife. Often, both sides provide at least some gifts or resources, but there is often an imbalance in one or the other direction. The criteria for selecting possible matches also vary substantially. Because arranged marriages often involve establishing relations between families and entail the distribution of family property, wealth and community status figure prominently in many practices. Religion, character, and reputation also are important. The individual capabilities and achievements of the potential spouses may matter to varying degrees—traditionally, brides and grooms may be expected to demonstrate skills relevant to their roles as spouses.

Perhaps most importantly, arranging practices also vary in terms of who does the arranging. In many instances, parents serve a primary role, but cultures vary in the extent to which fathers versus mothers or both parents are involved. Furthermore, in most cultures with arranged marriages, the arrangement engages a variety of individuals in addition to parents, as other parties are consulted. For example, in traditional Hindu arrangement practices, uncles and priests may be consulted for help in identifying and evaluating potential suitors or brides even when parents make primary decisions. The relative power and involvement of the to-be-married individuals varies extensively, from approaches in which the potential spouses can only resist via extreme measures, such as feigning insanity or illness, to approaches in which the potential spouses have full veto power over a potential match. In some cases, the power of the potential spouses to refuse a match varies as a function of gender, with males having more power to refuse than females. Related to the power of potential spouses to refuse a match is the possibility of premarriage contact. Typically, arranging practices that permit more premarriage contact have more scope for potential spouses to develop their own opinions and to provide input. Such contact, however, is not like Western ideas about dating and courtship—continuing to meet with a potential partner carries strong commitments.

Comparing Love and Arranged Marriages

Comparisons of love and arranged marriages often examine either divorce rates or marital satisfaction. Those comparisons, which involve a tiny subset of the array of places in which marriages are arranged, typically show equivalent or lower divorce rates for arranged marriages and equivalent levels of marital satisfaction. There are many problems with interpreting these findings because people who enter into arranged marriages differ from those in love marriages in many respects, even when researchers are looking at love and arranged marriages within a single culture. For example, arranged marriages may have lower divorce rates because the culture as a whole has lower divorce rates or because they involve individuals with more traditional values and a willingness to stay in a marriage that is less than optimal. Lower divorce rates may arise because arranged marriages occur in social systems where women are viewed as the property of men and are therefore unable to exit their marriage, because arranged marriages involve social groups where divorce is negatively stigmatized, or because of a complicated interplay among these factors.

Two other issues bear mention. Although on the surface choosing spouses on the basis of family status, religion, reputation, and other issues that often play a role in arranging marriages looks very different from choosing spouses based on love, both these methods may result in choosing spouses who are similar to each other. At least for younger couples, similarity has been linked to high levels of marital satisfaction. Second, equivalent divorce rates and satisfaction levels may be linked to different underlying processes. For example, couples in love marriages may base marital satisfaction on different factors than do couples in arranged marriages, and the factors predicting how marital satisfaction changes over time may be different in the two types of marriages. These two issues represent important ones for future research that compares love and arranged marriages.

Concerns Regarding Arranged Marriages

Scholars studying arranged marriages sometimes express concerns with the implications of

arranged marriage practices for individual autonomy and broader issues of how different cultural traditions may coexist in pluralistic, multicultural societies. On the one hand, societies that practice arranged marriage are often societies in which men and women are not viewed as equal and in which there is evidence for the oppression and abuse of women (and often children). On the other hand, most scholars note that the issues are very complex because the variety in practices across cultures and over historical time is very large.

ASIAN-AMERICAN FAMILIES

Asian Americans represent more than 28 subgroups who share common ethnic origins in Asia and who share similar physical appearances and cultural values. Some Asian Americans immigrated to the United States in the late 19th century and early 20th century, while other more recent immigrants or refugees arrived after the 1965 Immigration Reform Act. Therefore, a single classification of Asian Americans masks important differences within Asian-American groups in terms of immigration experiences, occupational skills, primary languages, income, education, average ages, and ethnic identity.

Considering this diverse background, to speak of the Asian-American family is to ignore the great diversity in the structures, lifestyles, and experiences of such families. This entry describes general patterns of Asian-American families, but it is important to remember the diverse family experiences of Asian Americans.

In general, Asian-American families have frequently been considered problem-free because of their economic and educational success, low divorce rates, and strong family commitment. However, this model family image applies to more established Asian Americans such as Japanese and Chinese Americans rather than to more recent immigrants and refugees from Southeast Asia. Therefore, the variations within Asian-American families exist mainly due to differences in generations and time since immigration. This entry discusses several aspects of Asian-American families including mate selection, relationships between spouses, parent–child relationships, intergenerational relationships, and extended family.

Mate Selection

For many Asian Americans, marriage has been considered not just as a union between two individuals but also, and perhaps more important, as a union between two families. Therefore, Asian-American parents were often involved in mate selection for their offspring. This form of arranged marriage was particularly common among early Asian immigrants in the United States. For example, in the early 1900s, many Japanese male immigrants resorted to “picture-bride marriages” in which the partners knew each other only through the exchange of photographs before marriage. These prospective wives of Japanese men were frequently chosen by their parents and relatives back in Japan. Later generations of Asian Americans, however, have been more likely to select their future spouses based on individual factors. An increase in Asian-American interracial marriage (marriage between two people of different races) since the 1970s indicates that Asian-American marriage has become a matter of individual preference.

Relationships Between Spouses

Traditional Asian-American husbands often maintain an authoritative and dignified relationship to their wives. However, as succeeding generations of Asian Americans become more exposed to the mainstream culture, their marital relations become more like those of most White middle-class American families in which egalitarian couple relations are expected. For example, most Japanese and Chinese Americans who immigrated to the United States in the early 1900s tended to have more egalitarian marital relationships compared with Korean and Vietnamese Americans, many of whom immigrated to the United States after the 1965 immigration reform. This tendency suggests that Japanese and Chinese Americans, through longer contact and participation in the larger culture, are more likely to have absorbed the dominant cultural and familial values in the United States compared with recent immigrants from Korea and Vietnam. This assimilation perspective also partly explains a relatively large number of interracial marriages among well-educated and professional Japanese and Chinese Americans compared with their Korean and Vietnamese counterparts.

Parent–Child Relationships

Some studies on parent–child relationships report that Asian-American children are expected to comply with familial authority to the point of sacrificing their own desires and ambitions. Although this portrayal gives an authoritarian image of Asian-American parents, their relationships with children have been influenced by the diverse historical and immigration experiences of Asians in the United States. For example, Japanese-American parents lost their parental authority and supervision when they were interned during World War II. These parents' activities and contacts with their children were supervised and restricted in internment camps, giving Nisei (the second generation) children greater independence in their decision making. Parent–child conflicts are also reported among Korean-American children and their immigrant parents. It was found that Korean-American children who are proficient

in the Korean language have closer relationships with their parents than do their peers who are not. This relationship is generally found true between immigrant parents and their children among more recently immigrated Asian-American groups.

Although contemporary Asian-American parenting does not seem to differ significantly from that of European Americans, some studies have found that Asian-American parenting is unique in terms of communication styles by using indirect and nonverbal methods of communication. Additionally, many Asian-American fathers feel obligated to be leaders and the principal economic provider in the families. In contrast, many Asian-American women believe that their important family role is to monitor the emotional well-being of their families. These gender differences are more pronounced among Asian Americans compared to other ethnic and nonethnic groups. Consequently, Asian-American children usually report feeling emotionally closer to their mothers than to their fathers.

Intergenerational Relationships

Prior research has generally indicated that Asian Americans tend to have strong commitments to care for their elderly parents. Studies have shown that, compared to European Americans, Asian Americans, in general, feel more obligated to provide more financial aid and interact more frequently with their elderly parents. Asian-American elderly members also tend to live with their family members rather than in nursing homes, and family members of all age levels are typically integrated into family activities. Many younger Asian-American adults are also expected to live with their families until they marry. However, Asian-American intergenerational relationships are undergoing several changes. Among Japanese Americans, for example, retired Nisei, unlike Issei (first generation) parents, generally do not want to live with their children. It has also been reported that contemporary Japanese Americans are less likely to exchange resources between generations than are Chinese, Filipino, and Korean Americans.

Extended Family

Asian Americans are more likely to report sharing their thoughts and problems with their family members and relatives and helping each other than European Americans, the latter giving more emphasis to individual family members' right to privacy. The conventional explanation for the cohesion among family members and extended kin has been that Asian-American values emphasize family solidarity that is derived from Confucian ethics. However, this family cohesion can also be viewed as reflecting a familial response to external pressures on the family. For example, an immigrant Asian family that is coping with adaptation to American society or facing racism can find solace, strength, and identity by affiliating closely within the family. The emphasis on family cohesion could also reflect the historical need for all members of an Asian-American family to work together and cooperate to contribute to the financial support and functioning of the family.

It is difficult to speak of a singular Asian-American family experience. In tracing the diversity within Asian-American families, several sources of diversity should be noted. One is that the formation and maintenance of Asian-American families have been profoundly influenced by the immigration history and external hostility that Asian Americans have faced in the United States. Second, Asian-American family diversity is reflected in the differential experiences of men and women in different social classes. Many working-class Southeast-Asian refugee women are still reluctant to reject their husbands' authority, whereas middle-class Asian-American women who are often employed as professionals have a bargaining chip to negotiate for their husbands' greater involvement in household labor. Asian-American families will experience further intra-ethnic diversity as rates of interracial marriage continue to increase and generational differences divide the experiences of immigrant parents and native-born children. These changes indicate that each Asian-American population will continue to experience its own diverse family lives.

ASSESSMENT OF COUPLES

Assessing couples involves measuring relationship quality and other aspects of intimate dyadic relationships. Popular methods include self-report questionnaires for relationship satisfaction, communication behavior, and relationship cognitions, as well as laboratory-based observational methods, informal observation, and clinical interview. Although dyadic partners complete many measures individually, the conceptual focus in couples assessment is on relationship functioning. This entry examines conceptual issues and common approaches to assessing married couples and similar intimate dyads.

Measurement Questions About Dyadic Relationship Quality

The most widely used and cited measure of intimate relationship quality is the 32-item Dyadic Adjustment Scale (DAS) developed by Graham Spanier to measure the level of adjustment in heterosexual, homosexual, married, or unmarried cohabitating romantic dyads. Many writers have questioned whether a single self-report construct such as marital adjustment can represent the health or status of a relationship. The predominant belief is that global self-report measures reflect the overriding sentiment of the person

about the relationship, and this global construct is best termed relationship satisfaction.

Assessment of Couples' Distress as a Syndrome

Although most self-report marital assessment methods yield dimensional scores, investigators have used a range of strategies to dichotomize couples into happy or unhappy categories for purposes of treatment study selection or defining treatment success. These strategies have derived cut-points by comparing clinic versus nonclinic or treatment-seeking versus nontreatment-seeking couples. These strategies have obvious limitations; for example, it is clear that many unhappy spouses in poorly functioning relationships never seek or enter treatment, and certainly a portion of those relationships fail.

In the last two decades, some relationship theorists and therapists have sought formal recognition of diagnoses for types of relationship dysfunction, such as marital discord, in standard psychiatric diagnostic manuals. The empirical work on developing reliable and valid structured interview assessment methods to support this effort has been limited. Existing diagnostic interview assessments are modestly associated with cut-point strategies for dichotomizing successful and unsuccessful relationships.

Use of Assessment Results to Represent Couples' Relationship Functioning

The assessment of couples often occurs at the level of the individual, as in the self-report of relationship satisfaction, but the results from assessing two partners are often integrated in some way to represent the couple system in data analyses or in clinical description. There are various approaches, such as using the mean of the individual partners' scores or an index of the difference in their scores. These approaches have been criticized on the basis that they substantially obscure the contribution of individual partners' scores. The concept of *level validity* has been introduced to describe the degree to which individual family members' scores can be used to represent the couple (or larger family unit). Level validity can be examined using structural equations modeling in which the contributions of the scores of each type of family member (e.g., husband, wife) to the scores of the unit are estimated simultaneously.

Important Domains as Targets of Couples' Assessment by Self-Report and Related Methods

Both verbal and nonverbal interaction behaviors are recognized as key domains of evaluation. Assessment can focus on discrete behaviors (e.g., problem description, solutions) as well as on patterns that couples exhibit. The Response to Conflict Scale developed by Gary Birchler and colleagues is a 24-item checklist that assesses destructive interaction strategies, including "yelling or screaming," "swearing" and "criticizing" of both partners. The Conflict Tactics Scale, developed by Murray Straus, focuses primarily on verbal and physical abuse strategies. The Peterson Interaction Record (D. R. Peterson) is a less-structured measure that directs partners to record the context of couples' interaction and the sequence of the interaction; the form also invites differing perceptions of an event. The Communication Patterns Questionnaire developed by Andrew Christensen and Chris Heavey assesses the destructive demand-withdraw pattern that occurs when one partner attempts to engage, influence, or demand change, while the other partner avoids, withdraws, or stonewalls the first partner.

Relationship cognitions have also been shown to be important for the quality of relationships. Measures of relationship cognitions include attributional dimensions associated with depression (i.e., internal-external, stable-unstable, specific-global) as well as dimensions such as responsibility, blame, and attributions to malicious intent of the partner. Reliable measures with evidence of validity include the Marital Attitude Survey (Norman Epstein and colleagues), Dyadic Attributional Inventory (Donald Baucom and colleagues), and the Relationship Attribution Measure (Frank Fincham and Tom Bradbury). Measures of maladaptive relationship beliefs include the Relationship Beliefs Inventory (Norman Epstein and colleagues) and the Inventory of Specific Relationship Standards (Donald Baucom, Norman Epstein, and colleagues). Other methods, such as video-assisted recall (VAR) of relationship cognitions, are less practical but are used in research to ascertain novel types of cognitions. The VAR method involves replaying a couple's laboratory-based videorecorded communication sample to a partner from the couple, who is prompted at

regular intervals to pause and record his or her thoughts about the interaction as realistically as possible. The recorded thoughts are then coded using standard cognitive dimensions or novel coding categories.

Sexual functioning, a highly important aspect of intimate relationships, can be evaluated briefly using the Arizona Sexual Experiences Scale (developed by Cynthia McGahuey and colleagues) assessing sex drive, sexual arousal, penile erection or vaginal lubrication, ability to reach orgasm, and level of satisfaction with orgasm. More detailed assessment using a structured interview tool can be accomplished using the Derogatis Sexual Functioning Index (Leonard Derogatis).

The degree of positive and negative affect expressed by partners is another important area to assess. Clinicians typically assess this domain through informal observation during the clinical interview or by observing couples' communication. The most important factors include the degree to which partners reciprocate positive and negative affects, the intensity and degree of escalation of negative affect, and the degree to which negative affect is expressed across many situations. Affect can be assessed in research contexts using a video-assisted method in which partners provide continuous ratings of their own affect using a rating dial, while viewing a videorecorded sample of the couple's communication.

Multidimensional self-report measures such as the Marital Satisfaction Inventory (MSI) developed by Douglas Snyder and colleagues cover many of the key areas for assessment in a single instrument. The subscales of the MSI cover a wide range of aspects of couples' relationships including global satisfaction, affect expression, ineffectiveness of problem solving, and level of satisfaction in specific content areas (e.g., finances). The Style of Conflict Inventory, developed by Michael Metz, follows a cognitive behavioral framework by assessing both communication styles (e.g., engaging versus avoiding pattern) and partners' perceptions of their conflict.

Observational Methods

Laboratory-based observational assessment of couples' communication has been an established

research method for close to four decades. The most common procedure involves having a couple discuss a specific issue or problem for a discrete 10-to-20 minute time period in an attempt to solve, or come to a resolution, on the topic. The discussion is videorecorded and later rated by trained observers using a coding scheme devised for the purpose.

Coding schemes have typically focused on a broad range of problem solving and affective behaviors, although more recently investigators have devised systems to assess social support behaviors. The Marital Interaction Coding System (MICS) and related systems, developed by Robert Weiss and others, assesses rates and sequences of specific units of spouses' behaviors. The Specific Affect Coding System developed by John Gottman focuses on physical, facial, vocal, and verbal behavior to code a range of positive and negative affective states. Other coding systems use ratings of behavioral dimensions (e.g., criticism) based on specific time units across the recording period to characterize couples' communication. Data analyses have typically used two basic strategies: percentages or rates of categories of behavior and the analysis of sequential association of partners' behaviors over time.

Physiological Measures

Marital quality and couples' conflict have been shown to have significant physiological correlates—including long-term physical well-being of intimate partners and even outcomes such as the rate of wound healing. There are several physiological measures that have been linked to negative interaction patterns, primarily associated with endocrinological and immunological functioning. Excessive excretion of cortisol, a key hormone related to stress, has a negative impact on immunological regulation, as well as other physical risk factors such as osteoporosis and abdominal obesity. Cortisol levels, extracted from blood samples drawn at 15-minute intervals during a couple's communication interaction task, are associated with a range of observational and cognitive measures. Epinephrine, norepinephrine, growth hormone, and adrenocorticotrophic hormone (ACTH) also appear to be important physiological correlates worthy of measurement.

Clinical Interviewing and Assessing Couples for Treatment

Clinical assessment of couples typically has the following elements: partners' statement of key problems, relationship history, paper and pencil self-report of satisfaction and other domains of relationship functioning, and observation of the couple's interaction. The clinician may also assess individual histories and clinical symptoms depending on the presenting complaints and context of the treatment. Initial assessment often extends to two or three hourly sessions. Clinicians must strike a balance between getting sufficient, standardized information about the couple's problems and using methods that are acceptable and expeditious from the clients' points of view.

The relationship history entails the date and manner in which the couple met and includes the major phases and milestones for the couple (e.g., relationship development, marriage, and birth of children). It is important to observe the degree of partners' fondness for the other, use of relationship-oriented language, and negative attitudes during their reciting of the history. Observation of couples' communication in the clinical setting can occur as an unstructured observation as the assessment interview proceeds, or can follow the basic procedure of laboratory observational assessment with careful observation by the clinician. Using this latter strategy, termed analogue behavioral observation, the clinician can benefit from familiarity with well-validated and reliable observational coding systems.

ASSESSMENT OF FAMILIES

Four aspects of family assessment are discussed in this entry: (1) the purpose of family assessment, (2) the level of assessment, (3) the importance of content and construct validity, and (4) the level of analysis. Although this is not an exhaustive consideration of family assessment, these issues have been central topics for the past 30 years.

Purpose of Family Assessment

Scholars and practitioners from an array of disciplines (e.g., family studies, psychology, sociology, public health) are interested in family relationships, most typically as predictors of specific well-being outcomes such as individual development and health status. This interest has stemmed from the belief that family dynamics and relationships are fundamental correlates or predictors of individuals' cognitions, emotions, and behavior in close relationships and role settings.

Scholars' disciplinary orientation and research interests shape how family assessment is conceptualized and designed. For example, family studies

scholars have focused on the connections between subsystems or dyads within the family, such as marriage (or cohabitating) relationships and parenting. From this perspective, family is examined as a set of potentially interconnected dyads. Family studies scholars who have included an assessment of the whole family often have tried to sort out predominant influences. Do families as a whole matter or does dyadic functioning take priority as an influence of individual well-being? Do whole family system properties, such as cohesion, add any additional understanding to assessments of parent-child relationships, such as attachment, or assessments of marital relationships, such as intimacy?

Most scholars generally have approached the issue of family assessment in two different ways. Some disciplines, such as developmental psychology, have favored focusing on parent-child relationships as central correlates of child and adolescent development. Often properties of the parent-child relationship have been viewed as more central because they are thought to be more proximal to developmental outcomes than are whole family system properties. Recent theorizing has shifted a bit in this area with some scholars testing process models that suggest that certain family characteristics, such as cohesion or disengagement, moderate the relationships between parent-child properties and individual outcomes. Within this paradigm, family becomes one of the contexts for the effects of socialization influences on individual well-being.

Scholars in disciplines with a health and medical focus often have focused on the family system as a whole. They typically have tested and implemented practice models that suggest that family properties shape individual health outcomes, such as children's asthmatic symptoms, adolescents' use of condoms, and parents' cardiovascular health. Within this paradigm, scholars most often have conceptualized the family system as a holistic constellation of relationships and have assessed general family functioning or specific aspects of family process and structure such as openness and quality of communication among family members.

Although an extensive listing of family constructs assessed in the research literature is beyond the scope of this entry, a core of salient family constructs is feasible. Frequently studied family constructs have included adaptability, affective expression,

behavioral control, boundaries, boundary ambiguity, coalitions, cohesion, communication, conflict, coping, differentiation, disengagement, enmeshment, fusion, individuation, intimacy, and family stress.

Level of Assessment

There are four common levels of family assessment: families as a whole, triads, dyads, and individual family members. One controversial issue is whether the level of assessment must match the level of conceptualization. For example, when scholars study a child's involvement in parents' marital conflict, which is by definition a triadic construct, must the researchers collect information from all three family members? Although there has been little consensus regarding the issue of matching between the level of conceptualization and level of assessment, two conclusions have received a great deal of support. First, the conceptual definition of the construct must be explicit and must delineate the ways in which cognitions, emotions, and behaviors constitute the essential elements of the construct. This definition and delineation informs assessment decisions and affects the degree to which matching is necessary. Second, scholars must demonstrate a clear understanding of systematic biases that may occur when implementing specific assessment decisions and must design research in ways that minimize the chance that these biases affect the interpretations of the findings. For example, it is plausible that parents' depressive affect negatively skews their reports of children's behavior problems and that adolescents' attachment security increases their perceptions of positive parenting behaviors. In the context of these examples, without adequate consideration within the design and analysis, interpretations of results that derive from parents' reports of children's problem behaviors and adolescents' reports of parenting might be suspect because of the contaminating influence of parents' depressive symptoms or adolescents' attachment insecurities. In general, systematic biases can stem from the influence of related constructs, as illustrated in the above example, from family members' personality traits, from differences in developmental and relational expectations among family members, and from the implementation of specific data collection

methods, as in reactivity concerns that are present in observational methods.

A second controversial issue is whether the level of assessment must match the level of analysis. For example, do all three family members need to be included in the assessment procedure when the construct being assessed is triadic, such as youths' involvement in parents' disputes? Until recently this dilemma focused on (1) the use of aggregated scores, such as summed scores or discrepancy scores; and (2) the inclusion of individual scores within the same analytic model. Each procedure raised conceptual and methodological concerns, some of which have threatened the validity of interpretations of findings. Recent developments regarding the use of multilevel statistical analyses have provided exciting and innovative techniques for addressing this dilemma because both within (i.e., across family members) and between families hypotheses can be tested. The examination of within and between family hypotheses will advance the understanding of family dynamics and family influences on individual well-being.

A third important issue in decision-making regarding level of assessment is measurement equivalence. Measurement equivalence means that a given assessment means the same thing for different groups of respondents. This issue is particularly important when individual family members are reporters. For example, do measures of family communication quality mean the same thing to mothers and fathers? Do measures of parental harshness mean the same thing to African-American and Asian-American parents? The issue of measurement equivalence has been central to cross-ethnic and cross-cultural research but has not been adequately addressed in family assessment. Ethnic, racial, and gender equivalence (e.g., mothers and fathers, daughters and sons) needs to be examined carefully before testing substantive hypotheses regarding mean differences and patterns of family influence.

Content and Construct Validity

Content validity focuses on evaluating how well a given measure or assessment captures the conceptual domain of the construct the measure represents. It centers on identifying the constituent elements of the construct (i.e., what is in the domain and what is not). For scholars who assess

general family functioning, the key issue has been identifying central elements and using a valid measure that adequately covers the conceptual domain of family functioning. Past researchers have identified as few as 2 central elements and as many as 10. Ronald Sabatelli and Suzanne Bartle emphasized five that are important elements of general family functioning: (1) facilitating the development and enhancement of identity for individual family members and the whole family, (2) establishing and maintaining internal and external boundaries, (3) managing the emotional climate, (4) managing the use of family resources, and (5) identifying and addressing individual and system stress. Scholars interested in general family functioning would be well served to include assessments of these five aspects even when a single assessment score is desired.

Construct validity focuses on evaluating how adequately a given assessment tool measures the focal construct rather than other related and unrelated constructs. Scholars who are interested in assessing two or more aspects of family, triadic, or dyadic functioning need to ensure that the measures of two related aspects of family functioning occupy distinct conceptual domains. For example, scholars recently have shown that parents' use of psychological and behavioral control strategies are related but distinct constructs. Therefore, the measures of these two control strategies should have evidence of adequate discriminant validity (i.e., the part of construct validity that shows measurement distinction across different constructs). Conceptual clarity, discussed in the first section of this entry, provides a good foundation for ensuring this, as does identifying and minimizing general biases such as social desirability and reactivity that can cause two related measures of family process to become even more confounded. Discriminant validity also can be enhanced within a given study or intervention program by assessing some aspects of family relationships, such as perceived fairness, using self-reports, and other aspects, such as harsh communication, using observations or participants' daily time diaries. One of several reasons this is an important issue is because some researchers have found that how family members' feel or think about a particular relationship influences their behavior as much or more than their family member's preceding behavior.

Level of Analysis

Scholars have discussed and debated how to use multiple scores for a given family (e.g., observations of several family members, self-reports from mothers and fathers) in cases where a unitary family score is not obtained using an observational method and measure. A central issue has been whether or not to combine within-family scores to obtain one score for each family on any given aspect of family, triadic, or dyadic functioning. Scholars who have combined scores generally have chosen to either take an average to represent the family system or have created discrepancies scores that represent each family member's deviation from the family average. Each might be useful under certain circumstances, but conceptual and statistical issues must be considered carefully. Recent statistical advances emerging from the increased use of structural equation modeling have helped address this issue by allowing each family member's score to serve as an observable indicator of the unobserved construct being measured. This method creates a family score that is a weighted composite of the individual family member's scores. Structural equation modeling also allows the researcher to correlate the error terms that help control for some of the plausible systematic assessment biases identified in previous sections of this entry. This possibility has been described in the literature on family assessment as shared or correlated measurement error. Thus, interpretations of findings are less susceptible to inference problems when some of these potential dependencies that naturally occur in family assessment are accounted for in both the research design and in the statistical analyses.

Recent major innovations also have occurred in family assessment research with the increased use of multilevel modeling, such as hierarchical linear modeling. This technique allows for the simultaneous analysis of both within-family and between-family data. For example, one can examine differences among mothers', fathers', and early adolescents' perceptions of youth autonomy expectations within and across families. Researchers are now able to test process models that suggest different explanations for differences among family members than between families. These statistical advances, combined with greater attention to issues of conceptual clarity and valid measurement, have contributed to significant improvements in the assessments of

families that will enhance the efficacy and effectiveness of prevention and interventions focused on reducing family stress and improving functioning.

ASSORTATIVE MATING

Who one chooses as a partner is often thought of as an outcome of romantic love and mutual compatibility. However, on an aggregative level, individuals' decisions about who to marry, cohabit with, and date follow regular patterns. The tendency for individuals to form romantic relationships nonrandomly with respect to a given

characteristic or set of characteristics is referred to as *assortative mating*. Scholars have consistently found a strong tendency for individuals to choose partners who are similar to themselves (*homogamy*) on many characteristics including physical attractiveness, social status, educational attainment, IQ, and age. Individuals are also much more likely to marry within than outside their social group (*endogamy*) as defined by race/ethnicity, religion, and immigrant status. This entry describes why scholars are interested in assortative mating, outlines historical trends in matching patterns, and reviews recent research on differences in matching patterns by relationship type.

Patterns of assortative mating are of interest to social scientists for several reasons. First, marriage patterns are an indicator of a society's openness. Because marriage creates intimate ties between individuals and families, societies that have many marriages across social boundaries are thought to be more open than societies that have few. Second, patterns of assortative mating have consequences for the distribution of resources in societies. Because spouses share resources with one another and potentially one another's families, marriage within socioeconomic groups tends to reinforce inequalities across families, whereas random matching ameliorates inequalities. Third, to the extent that children's traits are learned or inherited from their parents, assortative mating has consequences for the population composition of future generations. Finally, patterns of assortative mating shed light on gender norms and inequalities. Because socioeconomic status often confers power in relationships, marriage patterns in societies in which most men marry "down" (*hypergamy*) may reflect and reinforce power disparities between husbands and wives.

Historical studies of assortative mating reveal broad shifts in mate selection patterns. In the United States, race/ethnic barriers to marriage have weakened considerably. Although still relatively rare, interracial marriages are now far more common than they were in the 1960s. Interreligious marriages are more common than interracial marriages and have also become increasingly common since the 1960s, but these changes have not been as dramatic as the increase in interracial marriage. By contrast, most studies have found that educational intermarriage has become less common in

the United States since the 1960s. In other countries such as Britain, however, educational intermarriage has become more common. Examining the overall resemblance of spouses masks significant changes in gender patterns of assortative mating. For example, since the 1970s, the likelihood that men marry women with less education than themselves has fallen substantially; so much so that in 2000, when one spouse had more education than the other, that spouse was more likely to be the wife than the husband. Thus, the traditional pattern of men marrying down has reversed.

Scholars have proposed several hypotheses to explain observed trends in assortative mating. Modernization theory predicts that as societies industrialize, the basis of success shifts from ascribed characteristics, or those characteristics inherited from one's parents such as race/ethnicity, class background, and to a large extent religion, to achieved characteristics, such as education. Adapting this theory to assortative mating, scholars hypothesize that matching on race/ethnicity, social background, and religion will decline over time whereas matching on education will increase, a hypothesis largely consistent with observed patterns. A related hypothesis is that individuals today have more freedom to intermarry because parents, religious communities, and other third parties have less control over young people's marriage choices as a result of increased geographic mobility and a prolonged interval between nest-leaving and marriage. Other scholars emphasize the potential link between economic inequality and assortative mating. They hypothesize that when economic inequality between groups is large, the "costs" of marrying down will increase, giving individuals a greater incentive to marry homogamously. The difference between the earnings of college graduates and those with less education has increased substantially over the past several decades, a trend that is consistent with the increase in educational homogamy. Finally, increases in educational assortative mating may also be the result of an increasing symmetry in the preferences of men and women for mates. As women have increased their labor force participation, men may have begun to compete for high-earning, highly educated women, just as women have traditionally competed for high-earning, highly educated men. Increasing symmetry of men's and women's preferences tends to increase educational

homogamy as a result of increased competition for highly educated mates.

Studies of assortative mating were once largely confined to marriage, but because of the increasing prevalence of cohabitation, there is a growing body of research on mate selection patterns among individuals who choose more nontraditional unions. The first studies on this topic compared the resemblance of married and cohabiting couples to better understand the nature and meaning of cohabitation. Because who one chooses as a partner may depend on the type of partnership sought, differences in partner selection provide insight into differences between relationship types. A common hypothesis is that individuals in the most committed relationships will be the most likely to be homogamous because heterogamous couples split up before moving to the next relationship stage. Empirical research is consistent with this claim: dating couples are the most likely to cross race/ethnic and religious divides, followed by cohabitators, and last by married couples. Other research has incorporated information on matching among gay and lesbian couples. These studies find that same-sex couples tend to resemble one another to a lesser extent than different-sex cohabiting and married couples on a variety of characteristics including race/ethnicity, age, and education. Specifically, same-sex male couples tend to resemble one another the least, followed by same-sex female couples, different-sex cohabitators, and different-sex married couples.

ATTACHMENT THEORY

Attachment Theory, originally formulated by John Bowlby and Mary Ainsworth, conceptualizes emotional bonds in close social relationships. Attachment Theory is one of the most influential psychological theories of the past half century, having generated thousands of published studies and scores of books. It has been adopted and used by all kinds of researchers, including developmentalists, clinicians, personality and social psychologists, and even psychologists who study groups and organizations. There are several reasons for the theory's success: First, it is both deep and broad. It has roots in psychoanalysis, cognitive developmental psychology, control systems theory, and primate ethology and has provided a new approach for social and personality psychologists who study social relationships in adulthood. Second, the theory was expounded very clearly and systematically in Bowlby's trilogy on attachment and loss—*Attachment* (1969/1982), *Separation* (1973), and *Loss* (1980)—one of the most thorough and coherent integrations yet achieved of clinical insights and diverse research literatures concerning the impact of close relationships on personality development and psychopathology. Third, although Bowlby was primarily a psychoanalyst and clinical theorist rather than a researcher, his close collaboration with Ainsworth, an empirically oriented research psychologist, resulted in measures and research paradigms that have been used effectively by basic researchers as well as clinicians. This entry briefly summarizes the current version of the theory, especially as it applies to adults.

The Attachment Behavioral System

According to Bowlby, human infants are born with a repertoire of behaviors (*attachment behaviors*) that were selected during evolution to increase the

likelihood of maintaining proximity to supportive others (whom Bowlby called *attachment figures*). Attachment behaviors include making eye contact, smiling, crying, calling, following, hugging, and clinging. Attachment figures—such as parents, grandparents, neighbors, older siblings, and daycare workers—typically protect a child from threats and dangers, provide encouragement and promote safe exploration of the environment, and help the infant learn to regulate emotions. Proximity-seeking behaviors are part of an adaptive behavioral system (the *attachment behavioral system*) that emerged over the course of primate evolution because it increased the likelihood of survival and reproduction in species whose offspring are born before they are able to walk, explore their environment, find food and water, or protect themselves from predators and other dangers. This behavioral system governs the choice, activation, and termination of proximity-seeking behaviors aimed at attaining an attachment figure's protection in times of need. Although the attachment system is most important early in life, Bowlby claimed it is active over the entire life span and is evident in thoughts and behaviors related to proximity seeking in times of need. This claim provided the impetus for subsequent theorists and researchers to conceptualize and study adult attachment.

During infancy, primary caregivers (such as parents) are likely to occupy the role of attachment figure. During adolescence and adulthood, peer relationship partners often become attachment figures, including close friends and romantic partners. Teachers and supervisors in academic settings or therapists in clinical settings can also serve as important sources of comfort and support. Moreover, groups, institutions, and spiritual personages (e.g., God, the Buddha, the Virgin Mary) can also be recruited as attachment figures. In addition, mental representations (thoughts, memories, images, conscious and unconscious) of attachment figures can serve as internal sources of support, comfort, and protection. They can also provide models of loving behavior that help a person sustain a sense of security even in the absence of physically present attachment figures.

From an attachment perspective, a specific relationship partner is an attachment figure, and a specific relationship is an attachment relationship, but only to the extent that the partner and

the relationship accomplish three important functions. First, the attachment figure must be viewed as someone from whom comforting proximity can be sought in times of stress or need, which often implies that a degree of worry, distress, and protest will arise if proximity to this person is threatened by separation or reduced attentiveness. Second, the person should be viewed as an actual or potential safe haven that can provide comfort, support, protection, and security in times of need. Third, the person should be viewed as a secure base, allowing a child or adult to pursue personal goals in a safe environment and to sustain exploration, risk taking, and personal growth. In other words, the attachment figure should be viewed as a haven of safety when the world seems dangerous and as an encourager and support provider when the world seems safe and offers interesting challenges for the development of skills and knowledge.

According to Bowlby, the goal of the attachment system is to increase a person's sense of security—a sense that the world is generally safe and challenging in a good way, that one can rely on others for protection and support when needed, and that one can confidently explore the environment and engage in social (affiliative) and nonsocial (skill learning) activities without fear of injury or failure. This goal is made particularly salient by actual or symbolic threats or by appraising an attachment figure as not sufficiently available or responsive. In such cases, the attachment system is activated, and the individual is motivated to reestablish actual or symbolic proximity to an attachment figure (a set of behaviors and behavioral tendencies that attachment researchers call the *primary strategy* of the attachment system). These bids for proximity persist until a sense of security is restored, at which time the individual comfortably returns to other activities.

During infancy, the primary attachment strategy includes mostly nonverbal expressions of need, such as crawling toward the attachment figure, reaching out to be picked up, crying, clinging, and so on. In adulthood, this primary strategy includes many other methods of establishing contact (e.g., talking, calling someone on the telephone, sending an e-mail or text message, driving to the person's workplace) as well as mentally

conjuring up soothing, comforting, encouraging mental representations of attachment figures. Such mental representations can bolster a person's sense of security, allowing him or her to continue pursuing other goals without interrupting goal pursuit to engage in bids for proximity and protection.

Bowlby described many of the adaptive benefits of proximity seeking. Becoming and remaining physically and emotionally close to another person is necessary for forming and maintaining successful, satisfying relationships. Moreover, seeking proximity to a loving, caring relationship partner helps a person learn to regulate and deescalate negative emotions, such as anxiety, anger, and sadness, which allows a person to be emotionally balanced and resilient in the face of life's inevitable stresses. Attachment security is also important as a foundation for learning about life's tasks and developing necessary and self-chosen skills of all kinds. A child or adult who feels threatened and inadequately protected or supported has a difficult time directing attention to free play, curious investigation of objects and environments, and affiliative relationships with peers. Extended over long periods, this kind of interference disrupts the development of self-efficacy, self-esteem, and trust in other people. Because of Bowlby's emphasis on felt security, he rejected theoretical formulations that equated attachment with excessive dependency or childishness. In his view, secure attachment provides a foundation for personal growth and mature autonomy, states that continue to involve successful close relationships.

Individual Differences in Attachment Working Models

Bowlby also discussed individual differences in the quality of attachment-system functioning. In his view, these individual differences reflect the sensitivity and responsiveness of one's past attachment figures to bids for proximity and support, and they take the form of internalized *working models* (i.e., expectations, cognitive schemas) of self and others in relationships. These ideas have been empirically supported in several longitudinal studies running from infancy to early adulthood.

Interactions with attachment figures who are available and responsive in times of need allow the attachment system to function smoothly and effectively. They promote a sense of connectedness and security, create positive expectations concerning other people's likely responsiveness and social support, and enhance perceptions of oneself as valuable, lovable, and special. When a person's attachment figures are not reliably available and supportive, however, a sense of security is not attained, working models of self and relationship partners contain many negative, distressing elements, and strategies of affect regulation other than normal proximity seeking (ones that Mary Main called *secondary attachment strategies*) are adopted and reinforced.

Attachment Theorists emphasize two secondary strategies: hyperactivation and deactivation of the attachment system. Hyperactivation is manifested in energetic, insistent attempts to get a relationship partner, viewed as insufficiently available or responsive, to pay more attention and provide better care and support. Hyperactivating strategies include being overly vigilant and intrusive regarding a relationship partner's interest, availability, and commitment or reliability; clinging to and attempting to control the partner; energetically attempting to achieve greater physical and emotional closeness, and being too dependent on relationship partners as constant sources of protection or reassurance. Deactivation of the attachment system includes inhibition or suppression of proximity-seeking tendencies and development of a personal style that Bowlby called *compulsive self-reliance*. Deactivating strategies require a person to deny or downplay attachment needs; avoid closeness, intimacy, commitment, and dependence; and maintain cognitive, emotional, and physical distance from others. They also involve active inattention to threatening events and personal vulnerabilities, as well as suppression of thoughts and memories that evoke distress because such thoughts might cause unwanted urges to seek proximity to and rely on other people.

According to Attachment Theory, a particular history of attachment experiences and the resulting formation of a person's attachment-related working models lead to relatively stable individual differences in *attachment style*—a habitual pattern of expectations, needs, emotions, and behavior in

interpersonal interactions and close relationships. Depending on how attachment style is measured, it includes a person's typical attachment-related thoughts, feelings, and behavior in a particular relationship (relationship-specific style) or across relationships (global attachment style).

The concept of attachment patterns or styles was first proposed by Ainsworth to describe infants' responses to separations from and reunions with their mother in a laboratory Strange Situation designed to activate the infants' attachment systems. Based on this procedure, infants were originally classified into one of three categories: secure, anxious, or avoidant. In the 1980s, researchers from different psychological subdisciplines (developmental, clinical, personality, and social psychology) constructed new measures of attachment style to extend attachment research into adolescence and adulthood. Based on a developmental and clinical approach, Main and her colleagues devised the Adult Attachment Interview to study adolescents' and adults' mental representations of attachment to their parents during childhood. In an independent line of research, Cindy Hazan and Phillip Shaver, who wished to apply Bowlby and Ainsworth's ideas to the study of romantic relationships, developed a self-report measure of adult attachment style. In its original form, the measure consisted of three brief descriptions of constellations of feelings and behaviors in close relationships that were intended to parallel the three infant attachment patterns identified by Ainsworth's Strange Situation research.

Hazan and Shaver's study was followed by hundreds of others that used the simple self-report measure to examine the interpersonal and intrapersonal correlates of adult attachment style. Over time, attachment researchers made methodological and conceptual improvements to the original self-report measure and reached the conclusion that attachment styles are best conceptualized as regions in a two-dimensional space. The first dimension, attachment-related avoidance, concerns discomfort with emotional closeness and depending on relationship partners, as well as a preference for interpersonal distance and self-reliance. Avoidant individuals, identified by using self-report measures, employ deactivating strategies to cope with insecurity and distress. The second dimension, attachment-related anxiety, includes a strong desire

for closeness and safety, intense worries about partner availability and responsiveness and about one's value to the partner, and the use of hyperactivating strategies (crying, begging, intruding, demanding) for dealing with insecurity and distress. People who score low on both dimensions are said to be secure or to have a secure attachment style.

Attachment styles are formed initially in early interactions with primary caregivers, a conclusion supported by much research, but Bowlby contended that notable interactions with significant others throughout life have the effect of updating a person's attachment working models. Moreover, although attachment style is often portrayed as a single, global orientation toward close relationships, there are theoretical and empirical reasons for viewing working models as parts of a memory network that includes a complex, heterogeneous array of specific and generalized attachment representations. In fact, research indicates that (a) people possess multiple attachment schemas, (b) that both congruent and incongruent working models can coexist in a complex memory network, and (c) that actual or imagined encounters with supportive or unsupportive interaction partners can activate particular attachment-related memories and expectations even if they are incongruent with a person's global attachment style. These various representations can be experimentally or therapeutically "primed" in order to change a person's attachment orientation in either the short run or the long run.

According to Attachment Theory, the physical and emotional availability of an actual security provider, or access to mental representations of supportive attachment figures, increases the sense of felt security and fosters a broaden-and-build cycle of attachment security. This cycle includes a cascade of mental and behavioral processes that increase a person's resources for maintaining emotional stability in times of stress, encourage intimate and deeply interdependent bonds with others, increase personal adjustment, and expand a person's perspectives and capacities (e.g., by allowing the person to be more creative, resourceful, or thoughtful). In the long run, repeated experiences of attachment-figure availability have an enduring effect on intrapsychic organization and interpersonal behavior. At the intrapsychic level, such experiences act as a continuing resilience resource,

sustaining emotional well-being and adjustment. At the interpersonal level, repeated experiences of attachment-figure availability provide a foundation for attachment security, which encourages the formation and maintenance of warm, satisfying, stable, and harmonious relationships.

Although secondary attachment strategies are initially aimed at achieving a workable relationship with a particular inconsistently available or consistently distant or unavailable attachment figure, they are often maladaptive when used in later relationships where proximity, intimacy, and interdependence would be more rewarding. Moreover, according to Bowlby, these insecure attachment strategies are risk factors that reduce resilience in times of stress or loss and increase the probability of emotional difficulties and poor adjustment. Anxious attachment encourages distress intensification and evokes a stream of negative memories, thoughts, and emotions, which in turn interferes with cognitive organization and, in some cases, precipitates psychopathology. Although avoidant individuals can often sustain a defensive façade of security and imperturbability, they ignore, misinterpret, or misunderstand their emotional reactions and have difficulty dealing with prolonged, demanding stressors that require active problem-confrontation and the mobilization of external sources of support. In addition, although avoidant individuals are often able to suppress or ignore distressing emotions, the distress can still be indirectly manifested in somatic symptoms, sleep problems, and other physical health problems. Moreover, avoidant individuals are prone to transform unresolved distress into hostility, loneliness, and estrangement from others.

Adult attachment research is currently being extended in studies of stress-related physiological processes (e.g., secretion of the stress hormone cortisol) and patterns of brain activation (e.g., overactivation of emotion generators and underactivation of frontal executive functions needed for emotion regulation). Moreover, what Bowlby called the attachment behavioral system has been linked to the functioning of other innate behavioral systems, such as caregiving, exploration, and sex, with results that are being applied clinically in individual and couples therapy. In sum, Bowlby and Ainsworth's concept of attachment has become central to most psychological subdisciplines, and

the scientific and clinical influence of Attachment Theory shows no sign of waning.

ATTACHMENT TYPOLOGIES, CHILDHOOD

John Bowlby and Mary Ainsworth, pioneers of Attachment Theory, have set forth several criteria

that need to be met in order for a relationship to be considered an attachment relationship. Attachment relationships in childhood have been described as enduring, emotional bonds that a child forms with a particular caregiver, typically a parent. Ideally, the relationship provides the child with security and comfort so that he or she can use the attachment figure as a secure base from which to explore the environment and as a safe haven in times of distress. The formation of attachment to caregivers is a normative event. That is, all children form attachments to their caregivers even if they do not receive adequate care. Attachment relationships are thought to be long-enduring, and the attachment figure is not interchangeable with another person. There is a desire to maintain closeness to the attachment figure and reestablish proximity if the bond is threatened. In an attachment relationship, a child may experience distress if separated from his or her attachment figure and will experience grief if there is permanent loss. This entry will focus on parent-child attachment during childhood (1 to 10 years of age).

This entry begins with a discussion of normative changes in the attachment system from infancy through middle childhood and then moves to a description of individual differences in the quality of attachment and on how differences in attachment organization are related to children's developmental outcomes. A number of complex issues surrounding measuring attachment during this age period are also highlighted. The entry ends with current directions in the study of attachment during childhood.

Changes in the Attachment System From Infancy to Middle Childhood

During infancy, children begin to organize their affect, cognition, and behavior in relation to a particular figure. Their behavior is organized around the set goal of the attachment system. The set goal refers to a desired state children try to achieve, which in infancy is proximity to an attachment figure. When infants experience a threat or distress, their attachment systems are activated and they will display several attachment behaviors (e.g., crying) to achieve the goal of proximity (e.g., physical contact with an attachment figure). Once

the goal is achieved, and distress is alleviated, the attachment system is less activated, and infants can explore their environment.

As children move from infancy to early childhood, there are some changes in the attachment system. One change is that children develop more elaborate internal working models, or representations, about the self and others. These representations develop from earlier interactions children have had with their attachment figures and include expectations for how others will react or respond to the child in times of distress, views about whether the world is an interesting place to explore, information about how conflicts are resolved, and information about how to cope with emotions. Additionally, there is an increase in the use of language during early childhood. This increase allows children and their attachment figures to talk about and make plans for situations that may be potentially upsetting. For example, attachment figures may reassure children that they will continue to be accessible and responsive.

As children enter middle childhood they experience many changes including increased time spent outside the home, shifts in their responsibility to assist in parental supervision, and greater contact with and interest in peers. They also experience changes in parent-child attachments. Some researchers have suggested that this is when the set goal of the attachment system changes from proximity of the attachment figure to the availability of the attachment figure. Children in middle childhood can tolerate longer separations and increased distance from attachment figures as long as they know that it is possible to contact the figure if needed. Another change during middle childhood is a decline in the frequency and intensity of attachment behaviors. For example, it is rare to see a 7-to-12-year-old child following and clinging to their attachment figure in the presence of a stranger, even though these behaviors were quite common during infancy and early childhood. Finally, as children enter middle childhood, they begin to share responsibility for communicating to and maintaining contact with the attachment figure. For example, children at this age must notify their parents about where they are and any changes that may occur in their plans.

Individual Differences in the Quality of Attachment

The above is a brief introduction to normative, age-related changes in parent–child attachment. However, the majority of attachment research has focused on individual differences (i.e., how attachments vary in quality), not normative changes. Although children’s relationships with their parents may vary in many important ways, Attachment Theory has conceptualized these variations in terms of attachment security, which reflects differences in how children organize their behavior in relation to an attachment figure. Further, Attachment Theory emphasizes that differences in attachment security reflect the strategies children develop to regulate contact with the attachment figure and thus represent adaptations to a particular caregiving environment.

Children who experience sensitive and responsive care are expected to form a secure relationship with their caregiver. A sensitive and responsive parent is able to notice his or her child’s communication signals, respond appropriately, and is warm, accepting, and affectionate. In this relationship, the child is able to use the parent as a secure base from which to explore the environment and as a haven of safety in times of distress. Additionally, because they have received sensitive and responsive care, securely attached children are likely to develop an internal working model of the attachment figure as sensitive and responsive and as an internal working model of the self as worthy of care. The perception of the attachment figure’s availability gives the securely attached child the confidence to explore new situations.

Children who are not able to use their attachment figures as a secure base and safe haven may develop insecure attachments to their attachment figures. Insecurely attached children have failed to develop confidence in the responsiveness and availability of the caregiver. There are three forms of insecure attachment that are characterized by avoidance, ambivalence, or disorganization in relation to a particular attachment figure. Each has been associated with a distinct pattern of caregiving.

Children who experience rejecting caregiving are expected to form an insecure-avoidant relationship with their caregiver. Rejecting parents tend to ignore or punish their child’s bids for contact and attention,

especially when the child is expressing negative emotions. Insecure-avoidant children are likely to develop an internal working model of the attachment figure as consistently rejecting. Because their parents reject the children’s expression of negative emotion, these children tend to minimize (i.e., hide or mask) their emotions. The minimizing of emotion is thought to be adaptive because it is a way for the child to maintain a connection with his or her attachment figure. That is, when insecure-avoidant children minimize their emotions, they reduce the risk of isolating themselves from their rejecting caregiver. Minimizing emotions to less stressful events also leaves open the possibility for the caregiver to be responsive if a more stressful or serious event occurs.

Parents of insecure-ambivalent children tend to be inconsistently responsive or somewhat inept at reading social signals of their child. As a result, children are unsure they can count on the parent’s support. Insecure-ambivalent children are likely to develop an internal working model of the attachment figure as inconsistently available and heighten their displays of emotion. Just as minimizing emotions is adaptive for insecure-avoidant children, heightening emotions is adaptive for insecure-ambivalent children because it serves as a way to maintain a connection with an inconsistently available caregiver (i.e., displays of emotion draw the attention of their attachment figure). By maximizing their emotions, these children are ensuring that their inconsistent caregiver will be available if a serious, stressful event does occur.

Parents of insecure-disorganized children are often psychologically unavailable. They may be coping with stress in their own lives such as adapting to their own loss or trauma (e.g., death of a parent) or marital problems. Other parents of insecure-disorganized children may be abusive or neglectful. Children who form a disorganized attachment to a caregiver are unable to use the attachment figure as a secure base or safe haven in a coherent and organized way. At times, they may show a combination of avoidance and ambivalence. These children also may show bizarre behaviors, such as freezing when the attachment figure is around because the caregiver is a source of fear as well as a safe haven (e.g., if the child has experienced abuse). Some older insecure-disorganized children respond to the psychological unavailability

of their parent by adopting the parental role, and the role reversal may be manifested in the child's either serving as a caregiver to the parent or treating the parent in a punitive way.

Associations Between Attachment and Developmental Outcomes

The quality of parent-child attachment has been found to have implications for later development. Attachment Theory predicts that children who form secure attachments will have a developmental advantage over children who form insecure attachments in terms of their ability to manage stage salient tasks. Securely attached children show benefits in areas such as school competence, self-concept, emotion regulation, peer competence, and lack of behavior problems. There is less consistent evidence regarding whether particular forms of insecure attachment are related to particular difficulties. Most research has investigated children's behaviors that are correlated with different categories of mother-child attachment.

School Competence and Self-Concept

The quality of attachment may be related to school competence in that securely attached children may show better adaptation to school due the sense of confidence, competence, and self-efficacy that they gain from experiencing a secure attachment relationship. Research generally supports this hypothesis. Secure attachment seems to be related to better adaptation to school as shown in children's work habits, attitudes, and persistence. However, secure attachment has not been consistently linked to intelligence or specific cognitive skills, although insecure-disorganized children have been found to have the lowest grades or performances on tests of cognitive skills.

Attachment quality may be related to a child's view of the self in that securely attached children who experience sensitive and responsive care are likely to view themselves as worthy of the care of others. Securely attached children are also predicted to have an open and balanced view of the self in that they can recognize their own limitations. Consistent with this hypothesis, securely attached children tend to report higher self-esteem and are reported by teachers to have

higher self-confidence. Securely attached children also tend to have positive views of the self and others. These linkages may be explained by the fact that secure children know that their attachment figure will be available if needed, and they view the self as worthy of care. By contrast, insecurely attached children may view their attachment figure as unavailable, unhelpful, and even hurtful, and they view the self as unworthy of care.

Emotion Regulation and Peer Competence

Emotion regulation is related in meaningful ways to Attachment Theory. Securely attached children use their attachment figure as a safe haven when distressed. Emotional distress is handled effectively in a secure attachment relationship, and eventually securely attached children may internalize effective emotion regulation strategies. Studies show that securely attached children do tend to use more constructive coping strategies such as support seeking or problem solving. Secure attachment is also related to more positive and less negative mood in daily interactions. Insecure-disorganized children are especially likely to show problems with emotion-regulation skills.

Attachment quality is also hypothesized to predict the quality of children's relationships with their peers. One reason is that a history of secure attachment is associated with the confidence to explore new environments, including environments involving peers. Another reason is that securely attached children learn how to behave in relationships through interactions with their caregivers. Additionally, as mentioned above, securely attached children have more effective emotion-regulation capabilities that are important for maintaining peer relationships. In empirical studies, securely attached children have been found to experience higher quality friendships and have higher peer competence. In terms of the relations of attachment to peer competence, insecure-avoidant children tend to victimize their peers while insecure-ambivalent children tend to be victims.

Behavior Problems

One of the most extensively studied propositions regarding the behavioral correlates of

differences in security of attachment is that a secure attachment relationship lays a healthy, solid foundation for development, while an insecure attachment relationship is associated with behavior problems. The results for internalizing and externalizing behavior problems are mixed, however. Although several studies have found that secure attachments are related to lower levels of internalizing and externalizing behavior problems, it is less clear how the specific forms of insecurity are related to behavior problems. Researchers predicted that internalizing behavior problems would be most related to insecure-ambivalent attachment, but studies have found that internalizing behavior problems are linked to insecure-avoidant, insecure-ambivalent, and insecure-disorganized attachment. Similarly, externalizing behavior problems have been linked to both avoidant and disorganized attachments.

Measurement

Initially, parent–child attachment was studied with infants, and measures were developed that could describe a child’s attachment behavior in relation to a particular parent. For example, some measures such as Mary Ainsworth’s Strange Situation procedures used separation-reunion procedures to assess attachment behavior. As researchers became more interested in studying attachment in older children, newer attachment measures were developed to assess attachment representations, which are scripts or schemas that capture children’s ideas about their relationship with an attachment figure. Representation measures include storytelling tasks or autobiographical interviews. Because of the developmental changes taking place throughout early and middle childhood, different measures may be more appropriate at different ages. For example, autobiographical approaches may be too cognitively demanding for a 6-year-old, while separation-reunion measures may not sufficiently stress an older child to invoke attachment behavior.

During infancy, there are validated measures of attachment, including the Strange Situation and the Attachment Q-sort that assess parent–child attachment by describing a child’s secure base behavior in relation to a parent either at home or

in the laboratory. In early and middle childhood there is not yet a single standard for measuring attachment. Behavioral observations (separation-reunion procedures) are most common for 3-to-6-year-olds. Story stem techniques (i.e., asking children to complete attachment-themed stories) are most common for 3-to-12-year-olds. Questionnaires that assess security, avoidance, or ambivalence are common for 9-to-18-year-olds. Autobiographical interviews are common for children 11 years or older. None of the measures used after infancy have been validated to the extent of the Strange Situation. However, there is some evidence for validity for these measures as behavioral observations of 3-to-6-year-olds have been found to be related to earlier Strange Situation assessments, and observational measures of attachment in early childhood are related to representation measures of attachment in early childhood and middle childhood.

Current Directions

As is evident from the measurement section, there is a great need to give more consideration to how the manifestations of attachment change over time. Relatively little research has documented age-related changes in attachment, especially beyond early childhood. Across childhood and adolescence, individuals experience multiple attachment relationships. Adolescent children are thought to have the ability to form generalized representations of attachment, or to have a state of mind in regard to attachment. It is not yet known how experiences in individual relationships come to be integrated into a generalized representation. One’s conceptualization of attachment also has implications for which form of measurement is appropriate. With the recent proliferation of measures, it is important to evaluate specific evidence that any measure labeled as *attachment* is in fact valid for assessing the phenomena specified in Attachment Theory.

One important limitation of attachment research is that most studies to date have focused only on mother–child attachment. Only a few studies have demonstrated that fathers contribute a unique, rather than a redundant, role in children’s development. To fully understand how parent–child

attachment influences developmental outcomes, however, it may be necessary to examine both mother–child and father–child attachment across childhood. In addition, more information is needed about the little studied role and importance of nonparental attachment figures such as siblings and grandparents.

Additionally, it is important to remember that attachment is just one source of influence on child development. More research should examine how attachment, in combination with other aspects of social experience, influences children's development. For example, the finding that attachment influences peer relationships should inspire research on how early attachment history and previous peer experience work together to influence children's later peer relationships. Another direction is to examine variables that may explain the links between attachment and peer relationships.

ATTRACTION, SEXUAL

Sexual attraction is a feeling of attraction to another person on the basis of sexual desire. Sexual attraction differs from other types of attraction such as friendship attraction in that it involves a component that is specifically sexual. For example, research has shown that there are two general types of love: passionate love, which is an intense feeling of longing for union with another, and companionate love, which is a warm feeling of affection and tenderness for those with whom people's lives are deeply connected. Sexual attraction is a particularly important aspect of passionate love but is much less relevant to companionate love.

There are several ways that researchers measure people's feelings of sexual attraction to another person: *sexual desire* (a motivational component that refers to a wish, need, or drive to seek out sexual objects or to engage in sexual activities), *sexual behavior* (a behavioral component, often assessed by determining how frequently couples engage in various sexual behaviors such as kissing, petting, and intercourse), and *sexual feelings* (an evaluative component including feelings of satisfaction, intimacy, and pleasure). Although sexual desire, sexual behavior, and sexual feelings often co-occur within a given sexual interaction, they are considered separate and distinct phenomena. For example, people can engage in sexual activity when they have little or no sexual desire, a phenomenon called *sexual compliance* or *consensual unwanted sex*. Similarly, people can experience sexual desire

and engage in sexual behavior but not find their experiences to be particularly pleasurable or satisfying. This entry examines the factors that influence sexual attraction, the features people are sexually attracted to, the people found to be sexually attractive, the reasons people engage in sex when they are sexually attracted, and the ways sexual attraction changes over the course of relationships.

What Influences Sexual Attraction?

Several theories attempt to explain the factors that influence sexual attraction. Social context theories focus on the proximal influences of sexual attraction, such as the social and cultural environments. According to these theories, sociocultural scripts guide people's attitudes, behaviors, and experiences with sexuality, including the factors that people perceive as sexually attractive. For example, in contemporary Western cultures, it is not viewed as acceptable to desire individuals much younger than oneself, especially those who are not yet socially considered to be adults. However, in other cultures, individuals, especially women, enter into marriages when they are in their teens. In contrast to social context theories, evolutionary theory considers the distal influences of sexual attraction, including how natural selection shaped sexual attraction in the time of the hunter-gatherers. Reproduction is an essential part of evolution; therefore, those traits that allowed hunter-gatherers to better survive and reproduce are now viewed as more sexually attractive. According to this theory, traits that signify health and fertility, such as facial symmetry and a fit body, are considered to be more sexually attractive.

Both of these theories attempt to explain why individuals find certain features, such as a beautiful face, to be more sexually attractive than other features. Social context theories consider current influences such as society and culture, allowing for differences in sexual attraction within different environments. Conversely, evolutionary theory attempts to explain the universality of sexual attraction, based on the traits that enhanced survival and reproduction during hunter-gatherer times. Despite their different approaches, both theories focus on gender differences in what is considered to be sexually attractive.

Which Features Do Men and Women Find Sexually Attractive?

Men and women both describe physical attractiveness as an essential part of sexual attraction as it is often an indicator of social success and physical health. Facial symmetry is a specific feature that enhances physical attractiveness. Both men and women who have more symmetrical faces are viewed as more physically attractive than those with less symmetrical faces. Other important features of physical attractiveness are prominent cheekbones, shiny teeth, a wide smile, and baby-like features such as large eyes. In men, a strong chin is also considered physically attractive. Body size is also an important component of physical attractiveness. In Western cultures, people report that thinner or average size individuals are more attractive than individuals with extremely thin or extremely overweight body sizes. For women, a thinner waist and wider hips (with the ideal waist-to-hip ratio being .7) is more attractive, whereas men with straighter hip-to-waist ratios (.8–.9) are viewed as more attractive. Other features that influence sexual attraction in addition to physical attractiveness are cultural success, wealth, personality, and sexual fidelity. Many of these features of sexual attraction are gender-specific. For example, women are more sexually attracted to men who exhibit personal success and have kind and caring personalities. These features, though still influential, are not as important for men. On the other hand, sexual fidelity is an aspect of sexual attractiveness that is more important to men.

Although some components of sexual attraction are thought to be universal, such as facial symmetry and hip-to-waist ratios, it is important to remember that many of the components of sexual attraction are culturally variable. For example, although thinner bodies are reported to be more physically attractive in general, there are certain cultures that view more overweight bodies as more attractive. In these cultures, body size is indicative of wealth, and a heavier body indicates a wealthier status.

To Whom Are People Sexually Attracted?

The majority of people report sexual attractions to members of the other sex, yet a sizable minority of

people report that they are attracted to members of the same sex. Sexual attractions to people of the same sex or the other sex have historically been measured with a Kinsey rating, which ranges between 0 and 6. A rating of 0 represents exclusive other-sex (i.e., heterosexual) attractions, a rating of 6 represents exclusive same-sex (i.e., homosexual) attractions, and a rating of 3 represents equal degrees of same-sex and other-sex attractions. In a nationally representative sample of 18-to-44-year-old men and women, 92 percent of men said that they were attracted only to females, 3.9 percent said mostly to females, and 3.2 percent said to only or mostly to males or to both males and females equally. Eighty-six percent of women said that they were attracted only to males, 10 percent said mostly to males, and 3.4 percent said only or mostly to females or to both females and males equally.

Some people, who later identify as gay or lesbian, report that they were unaware of same-sex attractions in childhood and early adolescence, whereas others report that these attractions were present at an early age. The propensity to experience same-sex attractions is not as stable as once believed, particularly for lesbian women. Lisa Diamond tracked a group of women over a 2-year period and found that half of the women in her study relinquished their initial sexual minority identity (e.g., they originally identified as lesbian or questioning and later identified as heterosexual or bisexual). Women tend to be more flexible in their same-sex attractions over the course of their lives than are men. Although researchers do not yet know why, it is possible that different neural and hormonal processes may underlie the development of sexual orientation in men and women or that rigid gender socialization for boys and men may lead to the suppression of male same-sex sexual desires.

Why Do People Engage in Sex When They Experience Sexual Attraction?

Why people engage in sex when they feel sexually attracted to a partner is referred to as *sexual motives*. People may engage in sex for *self-focused motives* such as to pursue their own physical pleasure or to avoid their own feelings of guilt from turning a partner down. They may engage in sex

for *partner-focused motives* such as pleasing their partner or preventing their partner's disappointment from being turned down. People may also engage in sex for *relationship-focused motives* such as increasing intimacy or avoiding conflict in their relationships. Reasons for engaging in sex can change over the course of sexual interactions. For example, a man may initially pursue sex to experience his own physical pleasure but may become increasingly focused on feeling close to and pleasing his partner over the course of an interaction. People's sexual motives may change across the course of the life span, such as in cases where boys engage in sex to impress their friends during their adolescence but find that this reason loses importance with increased age.

Engaging in sex repeatedly for particular reasons may lead people to develop a particular orientation toward their sexuality. For people who hold a *recreational orientation* to sex, the primary goal is to experience physical pleasure. In contrast, for people who hold a *relational orientation* to sex, the primary goal is to express love and affection for one's partner. There are important differences between men and women in these two relational orientations. Whereas men are more likely than women to adopt a recreational orientation in which no particular emotional relationship is needed as a prerequisite for sex, women are more likely than men to adopt a relational orientation in which sexuality is seen as an integral part of an ongoing relationship. It is important to point out that these male-female differences are the most dramatic during adolescence and young adulthood and may change over the course of time in relationships.

How Does Sexual Attraction Change Over the Course of Relationships?

Feelings of sexual desire or attraction to one's partner are higher and lower at different points in relationships. Sexual attraction plays an especially important role in the beginning stages of romantic relationships as partners are just beginning to fall in love and develop a relationship. In the American Couples Study of married, cohabiting, and gay and lesbian couples, the couples who engaged in sex the most frequently had been together for 2 years or less. In short, sexual desire typically peaks at the beginning of relationships as couples

are just getting to know each other and often decreases over the relationships, with the fastest rate of decline in the first several years. The transition to parenthood is one phase of relationships that involves dramatic life changes and adjustments, including changes in sexual attraction. Women's interest in sexual activity declines during pregnancy, reaching a near zero point during the immediate postpartum period, and then slowly increasing in the months after childbirth. Although male sexual desire does not decrease as dramatically as female desire during pregnancy and shortly after the birth of a child, some men also report decreased interest in sex due to fears of hurting the fetus and to the changing body of their partners.

Men's and women's sexual interests continue later in life but may be compromised by factors such as declining health of oneself or one's partner. In the National Survey of Families and Households conducted in 1988, whereas the frequency of marital sex was approximately 12 times a month for couples ages 19 to 24, it declined to 5 times a month for those ages 50 to 54, and 2 times a month for those ages 65 to 69. Despite the fact that they may be engaging in sexual activity less frequently than when they were younger, many older couples still view sex as especially important, meaningful, and satisfying, sometimes even more so than in their younger years.

In conclusion, there is a huge amount of variability in people's feelings of sexual attraction to another person. People can be attracted to different sorts of physical or personal features, people can desire partners of the same or other sex (or both), and people can engage in sex for a variety of reasons that change over the course of their lives and relationships.

ATTRIBUTION PROCESSES IN RELATIONSHIPS

General research on attribution addresses a wide range of judgments and cognitions that occur during person perception and social interactions. Fritz Heider's seminal work on person perception, "The Psychology of Interpersonal Relations," provided the impetus for decades of research on how people explain the behaviors of others, a body of work that has fallen under the broad label of *attribution*. The most common use of the term within the research literature refers to judgments about the perceived causes of human behavior, emphasizing how laypeople generate common-sense explanations for the behaviors of others or themselves. The traditional focus of research within attribution work, then, is determining how people go about answering the question of "Why?" when they attempt to explain human behavior. Such explanations consist of potentially innumerable causes, consequences, and contexts. The following entry first summarizes the nature of general attribution work within the field of social psychology. The focus then shifts to attributions as they relate to the study of relationship

processes. A final section briefly notes a challenge facing attribution theory in general and within relationship research specifically.

General Attribution Research: Judgments of Cause

Attribution researchers recognize that individuals' judgments of cause may be accurate to varying degrees. However, regardless of their accuracy in any objective sense, such causal explanations are ubiquitous in social interaction and have significant consequences for a wide range of social phenomena, including social relationships.

As a judgment of cause, attributions are frequently classified as either internal or external to an actor. This classification is also sometimes referred to as the distinction between dispositional or situational attributions, respectively. For example, within the context of relationships, one partner's apparently irritable mood may be explained by the other as resulting from a general disposition toward irritability, an internal or personal cause. Alternatively, the partner may more charitably explain this behavior with reference to some outside stressor, such as an unusually challenging day at work, an external or situational cause. Although the specific attribution may be more or less accurate in that given episode, the attribution generated by the partner can potentially influence the emotional reaction toward the other person, as well as subsequent behavioral interactions. The irritable mood explained away as the result of a "bad day" can be quickly forgotten and even excused. However, the irritable mood that is interpreted as symptomatic of a faulty or inherently difficult personality is less likely to be so quickly dismissed or excused. That particular attribution can potentially affect subsequent interactions between the couple or even engender doubt about whether the relationship should be maintained.

In addition to explaining a partner's specific behavior, the internal versus external (i.e., personal versus situation) distinction may also apply to judgments regarding an overall appraisal of the relationship's status. When evaluating one's relationship in a global sense, its apparent failure (or success) may be attributed to stable factors internal to a partner, such as flawed personality, or

to factors external to the partner, such as stress brought on by economic challenges. This act of explanation has numerous potential consequences for a relationship in terms of the individuals' interpretation of a particular interaction, their emotional and behavioral reactions to that interaction, and their expectations for future interactions. These lay attributions of cause are therefore central to understanding the psychological processes that characterize relationships.

Following Heider's analysis, many lines of inquiry emerged that ultimately helped guide research on interpersonal relationships. An influential model of correspondent inference proposed by Edward Jones and Keith Davis suggests that perceivers typically use information about another's behavior to draw inferences about that person's overall personality. Hence, a person's generous behaviors are frequently interpreted by others as evidence of a generous personality, and a risky behavior can be used to infer a generally risky disposition. The task of identifying the conditions under which perceivers make such personality inferences and how they may take into account external situational factors has been a prominent theme within attribution theory. Other approaches to understanding how people ascribe causal influence include Harold Kelley's model of covariation, which asserts that when attempting to explain another's behavior, people compare an actor's present behavior to past behavior, behavior in other similar situations, and the behavior of other people. Essentially, Kelley suggested that perceivers often have a wide range of information from which to infer the causes of another person's behavior. This model assumes that knowledge of the actor's behavior on multiple previous occasions is available, as would be the case for partners in an ongoing relationship who have interacted with each other in multiple contexts.

In addition to the internal versus external distinction, further dimensions of causal attribution have been identified, including perceived controllability, stability, and globality, with much of this work examining the emotional and behavioral consequences of particular attributions. For example, if an individual fails to obtain a desired promotion at work, that person's spouse could attribute that failure to factors under the person's control (e.g., lack of effort) or to factors outside

the person's control (e.g., lack of ability). Although the failure in and of itself is disappointing, a person will likely be judged more harshly by a spouse if the cause of that failure was seen as controllable (and hence avoidable). In aggregate, an impressive body of knowledge has accumulated regarding how individuals' judgments of causality predict social judgments in domains such as achievement, failure, aggression, helping, and reactions to stigmatized others. The richness of attribution theory ultimately provides a useful framework for research on the specific topic of relationship processes.

Attributions, Relationship Satisfaction, and Relationship Maintenance

In relationships, the mutual exchange of thoughts, emotions, and behaviors between two partners presents a complex, dynamic set of constructs, with attributions serving as one component within this network. Investigators have sought to identify whether the attributions generated within relationships predict a variety of outcomes. Perhaps the most widely studied of these is relationship satisfaction, and a large body of work has confirmed the general association between attributions and relationship satisfaction. Essentially, the types of explanations individuals offer for their partner's behaviors predict the quality of that relationship, as individuals in satisfying relationships tend to attribute negative relationship events to causes external to the partner, and attribute positive events to the internal, enduring aspects of the partner. In less satisfying relationships, the pattern is often reversed, with negative relationship events more likely to be attributed to enduring, stable characteristics of the partner. Furthermore, attributions and behavior may show a vicious cycle in such situations. Negative attributions to a partner can contribute to a partner's dissatisfaction, which in turn contribute to additional negative relationship behavior. The opposite cycle may be facilitated by positive, relationship-enhancing attributions.

Attributions and Emotions Within Relationships

Recent research has explored more precisely the various roles attributions play in the maintenance of relationship satisfaction. Of particular concern

is identifying how specific attributions relate to other cognitions and emotions that influence, and are influenced by, relationship satisfaction. Scholars are beginning to illuminate the specific roles attributions may play within relationship maintenance, with particular attention to emotions. For instance, recent work suggests that when an individual has a generally positive evaluation of a partner, certain kinds of attributions may specifically serve to maintain that overall good feeling during those occasions when the partner does something objectionable. For example, a husband who does not complete a household chore as promised may have his behavior explained by his wife in terms that could either maintain or threaten her overall positive regard for her husband. An attribution of "he's just having a particularly busy day and must have forgotten" can help protect the overall positive view of him, as it generates an emotion such as sympathy in response to the present transgression. In contrast, an attribution of "he's not doing what he promised because he is selfish" not only explains the immediate behavior in a negative way that can generate anger or frustration, but also it can potentially contribute to a more negative overall view of the partner. Attributions may therefore provide not only an explanation for a partner's particular behavior, but also help alleviate perceived inconsistency between how a person feels about a partner in general and how that partner is evaluated in a particular moment.

Attributions may also be influenced by the overall satisfaction and emotional environment of the relationship, suggesting bidirectional influences of attributions and emotions. For example, some evidence indicates that during a highly emotional interaction, the specific attributions one makes regarding a partner's intentions are partially influenced by one's overall relationship satisfaction. If the relationship is generally dissatisfying, negative attributions for a current, specific behavior become more likely. Hence, an individual's unwillingness to spend money for a home improvement may be interpreted by a partner as "trying to control all our money and trying to control me." In contrast, a relationship with less overall discord will enable more charitable attributions for the same behavior, such as "he [or she] is trying to be reasonably frugal but is just overdoing it in this case." Furthermore, emotional events external to the

relationship may also influence an attribution for a specific relationship event. Thus, stress originally caused by relationships with other family members or from difficulties in the workplace can contribute to an emotional environment in which relationship-threatening attributions generally become more likely as that negative emotion begins to permeate specific partner interactions. In sum, the explanations partners offer for each other's behavior can be both cause and consequence of the overall emotion that characterizes a relationship.

Attributions and Expectations Within Relationships

Certainly, an attribution's content is influenced by the particular, immediate behavior that is to be explained, the relationship context in which it occurs, and the emotional elements of the relationship. But attributions are also influenced by the relationship-relevant mental representations, expectations, and beliefs that people possess regarding the causes of others' behaviors. In a relationship, such expectations result in part from previous interactions with a partner and make the attribution process more efficient, helping to generate an explanation when the meaning of a partner's behavior may be ambiguous. However, such expectations and beliefs may also be due to factors external to the history of the specific present relationship. Attachment Theory describes one possible source of these factors and how they affect relationship cognition and attributions in particular.

Attachment Theory proposes that mental models (i.e., working models) of adult close relationships are influenced by people's previous experiences with childhood caregivers, experiences that can help build a general approach toward adult relationships. Such approaches, or adult attachment styles, may be broadly distinguished as secure versus insecure. Individuals with a secure adult attachment style typically approach relationships with trust and generally expect their partners to be dependable, providing comfort and support when needed. In contrast, individuals with one of several insecure attachment styles tend to view partners with less trust, elevated anxiety, and in some cases, dismissiveness. Such approaches can frame the kinds of attributions individuals make for their partners' behaviors, with securely attached people more likely

to make relationship-enhancing attributions for a partner's negative or ambiguous behavior, and insecurely attached individuals generating explanations that could threaten the relationship. Thus, a securely attached person can more readily explain a partner's lunch date with a group of friends in a benign fashion, construing it simply as an innocent event. In contrast, an insecurely attached individual with high levels of anxiety may view the same activity with suspicion or even dread, interpreting it to mean that the partner prefers to spend time with other people and that it may indicate larger long-term problems for the overall relationship. Attachment Theory highlights how the attributions that people make for their partners' behaviors are not just a function of the immediate information they have available but are also potentially affected by expectations developed as children.

Expectations that influence relationship attributions may also derive from the story-like narratives, or accounts, that people develop for the major events in their lives. Although people often create accounts for many life phenomena such as losses and accomplishments, relationship-focused accounts are particularly important, as people generate relatively organized narratives to explain relationship successes and failures. Accounts of past relationships can frame expectations for future relationships and thereby influence the attributions made in those relationships. A person who believes that a failed past romance progressed too quickly may resolve to take a current relationship more slowly and be hesitant to attribute the present partner's seemingly affectionate behavior to a loving and trustworthy orientation to oneself. Such hesitation may be threatening to the present relationship if the partner interprets it as a lack of interest or commitment. As with the influence of attachment styles, relationship-relevant expectations are not isolated from the past and can influence present attributions.

Conceptual Challenges Within Attribution Research on Relationships

Even though the term attribution typically refers to judgments of cause, research conducted under the umbrella of attribution has included numerous

types of inferences—the sheer number of which reflects the complexity of relationship-relevant cognition. Nonetheless, as numerous scholars have noted, the volume of interrelated constructs such as cause, intention, responsibility, and blame presents a challenge for the study of attribution. The term *cause*, as noted previously, broadly refers to the degree to which a person's behavior is explained by factors internal to that person or by factors external to that person. *Intention* refers to whether a person's behavior was undertaken purposefully or not, such that an angry outburst could be viewed as a momentary, involuntary loss of control, or as a deliberate, knowing attempt to intimidate a partner. *Responsibility* may be thought of as the degree to which a person may be held accountable for his or her actions, while *blame* is more akin to a moral judgment indicating condemnation for negative or harmful behaviors.

As relationship research on attributions has progressed, greater attention has been paid to such distinctions and has proven useful in some contexts. For example, responsibility and causal attributions do not necessarily predict other aspects of relationships in identical fashion, as evidence suggests that judgments of responsibility and intention, rather than causality, are more strongly associated with emotional reactions to a partner's transgressions. Hence, when explaining a partner's intentional act such as buying an expensive gift, judgments regarding that partner's state of mind (i.e., "She [or he] just wants me to be happy" versus "She [or he] might be feeling guilty for something I don't know about yet") may be more important than judgments of cause, *per se*. Future research is necessary to refine these distinctions between attributions of causality and responsibility and states of mind and how knowledge of such attributions and other cognitions enhance the prediction and understanding of satisfaction, emotion, behavior, and other outcomes within the domain of relationships.

AUNTS AND UNCLES, RELATIONSHIPS WITH

Family scholars are only recently beginning to understand the roles of aunts and uncles in families, when and how their relationships with nieces and nephews develop, and how these relationships spill over to influence other family members. Three broad issues are presented here: a summary of the factors that influence the development of relationships among aunts and uncles with nieces and nephews, a summary of the common ways such relationships emerge and their importance to families, and a summary of differences between aunts and uncles.

How Active Are Aunts and Uncles?

Uncles and aunts vary widely in the depth of their relationships with nieces and nephews. Some maintain close and long-standing relationships; some do not. The relative proportions of each are unknown. The closeness of adult siblings is an important determinant of the closeness of relationships among aunts and uncles with nieces and nephews. When adult siblings experience close relationships, they are more likely to develop and maintain relationships with each other's children, and when the relationships of adult siblings are estranged, their relationships with nieces and nephews are limited. As is often the case in families, women act as the primary kinkeepers and are often responsible for encouraging ties between their adult siblings and their children. The relationships of sisters are typically closer, relative to brothers. Sisters provide more help to family members, a wider range of help, and are more willing to engage in practical tasks like providing supplemental childcare when needed (i.e., *aunting*), and their willingness to send cards and gifts creates and maintains a familial sense of place, meaning, and ritual.

A variety of additional factors are central in influencing the relationships of aunts and uncles with nieces and nephews. Geographic distance can limit the development of their relationships, while on the other hand, living in close proximity can encourage such developments. But simplistic equations are not terribly insightful or predictive of the course of

personal relationships among kin. Contemporary mediums such as cell phones, personal or family Web pages, and e-mail can and do ameliorate the challenges of maintaining long-distance relationships by offering a convenient means by which family members can observe frequent contact and keep informed of one another's daily lives. In many cases, social distance—or how close or distant family members feel to one another—trumps geographic distance as an influential factor. Other factors like time-intensive careers and family obligations can impede the development of relationships among aunts, uncles, and children. On the other hand, less intensive personal obligations permit developing closer relationships. Childless aunts and uncles seem to become more involved with nieces and nephews relative to those adult siblings who become parents. Childless aunts and uncles indicate they have more time available for children as well as an expressed interest in mentoring children. For some, relationships with nieces and nephews may be their only opportunity to become involved with children. The experience of parental separation and divorce complicates relationships, and in such cases, aunts and uncles can serve as important confidants for both parents and children.

Generally, closer relationships among aunts, uncles, nieces, and nephews emerge when adult siblings are engaged in one another's lives, when they share similar values that emphasize maintaining family relationships, when aunts and uncles experience a sense of personal commitment to their nieces and nephews, and when they simply like one another because of similar dispositions and interests. If they happen to live near one another, all the better, but it is neither necessary nor essential.

With regard to race or ethnic differences in *aunting* and *unclying* among North Americans, little is known. Black Americans relative to Whites have somewhat different patterns of kin support and involvement, and these differences largely apply to comparisons of women. Black men and White men are similar in their involvement with kin and adult siblings. Black women are more involved in practical support such as help with transportation, household work and childcare, and Whites report more involvement in financial support and emotional support with kin. However, much of the difference is accounted for by differences in class

standing and income rather than cultural differences, and this seems to be the case for other ethnic groups as well. Generally, White, Black, and Hispanic families of similar income have similar levels of involvement with kin.

Regardless of race or ethnic backgrounds, kin invoke a strong sense of normative obligation to visit one another, exchange gifts on special occasions, and provide financial aid in a crisis. This does not mean all kin are viewed identically. People generally feel a greater sense of obligation to parents and to children and somewhat less to a core of additional kin members including grandparents, grandchildren, aunts, and uncles. Along with a general expectation to provide aid to nieces and nephews, there is also a parallel expectation to provide uncles and aunts with aid when needed. Finally, kin relationships vary in terms of the flexibility of the norms ascribed to them. For instance, people expect parents to support their children with very few exceptions. For collateral kin (i.e., aunts, uncles, nieces, and nephews), there is significant variation with some people reporting a much greater sense of obligation and others a much lower sense of obligation.

Basic Aunting and Uncling

Common themes in the family work of aunts and uncles include providing support and companionship, acting as confidants, and modeling alternative family or career choices. Aunts and uncles can supplement the work of parents in virtually all areas of the lives of their nieces and nephews. Their relationships change and adapt with the development of children and the needs of parents. During the labor-intensive years of infancy and early childhood, they can provide parents with supplemental childcare. During adolescence when issues of identity development are primary, they can ease or mediate conflicts between parents and teens, and just as importantly, they provide support for parents and act as their confidants. They can and do often become critical sources of support in times of special need such as with the death of a family member or in cases of separation and divorce. Aunts and uncles can mentor their nieces and nephews in spiritual or religious

matters, although the more formal role of godparent is understudied and largely unknown in its possible significance.

Under some circumstances, aunts and uncles replace absent parents or otherwise enact significant parental roles, and they are treated as such by their nieces and nephews. Aunts and uncles become surrogate parents for one of three reasons. Those aunts who live in extended family units sharing one home or neighboring homes in the presence of a sibling, and perhaps a sibling's spouse and children, may act as surrogate parents for the children. In other circumstances, aunts and uncles serve as parental figures when a parent, and usually a father, of a niece or nephew is absent, typically due to a divorce or problems related to substance abuse. Finally, some aunts, uncles, nieces, and nephews describe close relationships that seemed to be based upon opportunity (they see each other often and easily) and on personal preference in that they simply like one another. For many of these nieces and nephews, a favored relationship with an aunt or uncle supplements strong, positive relationships with parents, and they describe such kin as *like a dad* or *like a second mom*. For others, a conflict-habituated relationship with a parent is paired with an intimate relationship with an aunt or uncle who is considered in ways similar to a parent. In all of these cases, aunts and uncles intervene at times to provide housing for their nieces or nephews, sometimes temporary and sometimes on a more permanent basis.

In a variety of ways, aunts and uncles enrich the lives of their nieces and nephews. Their contributions are often highly valued, considered irreplaceable and unique, and derivative of the longevity of their relationships, knowledge of family members, and ostensibly more objective perspectives. At the same time, aunts and uncles are often deeply affected by their experience and sometimes mentored by the very children for whom they are responsible.

For an unknown population of nieces and nephews, relationships with uncles can be potentially abusive. Uncles, and more rarely nephews, relative to other family members, are a common perpetrator of the sexual abuse of nieces, and this condition appears to hold across cultures.

Gender Differences

Throughout the literature on parenting, friendship, and kinship, there is a consistent finding that the relationships of women are more expressive, relative to men. As is often the case in gender-based comparisons, the distributions are overlapping. Aunts and uncles share many similarities in their styles of mentoring and subjects of their concerns. Both aunts and uncles provide their nieces and nephews with advice regarding school and careers, as well as relationships with peers, parents, and other family members. And on occasion, they are critical about the choices or actions of their nieces and nephews. Nieces and nephews value similar features in their favored aunts and uncles, with displays of support and active listening with minimal judgment being chief among the most valued qualities. Differences in the mentoring styles of aunts and uncles appear, but often they are rather superficial.

In two areas, aunts and uncles do differ in important ways. Aunts and nieces talk more about relationship issues and, particularly, the intimate relationships of nieces. In this regard, aunts seem to know more about their nieces' relational lives than uncles do about nephews. Aunts offer their evaluations of the relational partners of nieces; they voice concerns about sexual activity, safety, health, and unplanned pregnancies. Aunts share their concerns about controlling and potentially abusive partners, often relating their personal experiences with such men. On the other hand, uncles do serve as role models, sometimes modeling positive relationships with other adults and children and sometimes rather negative relationships (as do aunts). Aunts simply become more knowledgeable about nieces' intimate relationships, and they express more concerns about issues of health and safety.

Aunts and uncles also differ in their perspectives on issues of personal development and the balance of work and family life. For aunts and nieces, the issue is critically important and often discussed. Aunts freely share their experiences of having

children while maintaining a career, or of working in fields typically dominated by men, and the challenges that face women in seeking a balance of personal, professional, and family lives. Uncles and nephews do not seem to discuss such issues with any regularity, or at least not as directly.

As aunts and uncles actively engage in the lives of their nieces and nephews, they also actively mentor parents. They do so by sharing their perspectives and their experiences or by otherwise serving as counselors, advisors, or supportive friends uniquely positioned because of their insider's knowledge and long-standing relationships with all family members.

In summary, the relationships of aunts and uncles with their nieces and nephews can be significant, influential, and of long duration. They are for an unknown proportion of families, and perhaps a substantial number, central figures mentoring children.

B

BANK ACCOUNT MODEL

Nearly everyone is familiar in theory, if not in practice, with the function of financial savings accounts. Money that is not required for day-to-day existence or an occasional indulgence is deposited into a savings account for a rainy day. Thus, depending on one's current financial situation, the account's balance continually shifts up and down. In the same way that one's savings vary, so too do romantic relationships. In some cases, relationships flow smoothly with both partners supporting each other and sometimes sacrificing for the good of the relationship. However, partners may on occasion behave badly, at times engaging in actions that endanger the relationships' strength and longevity. How can relationships persist when relational rainy days are unavoidable? One proposal comes from marital researcher John Gottman, who suggests that relationships may have accounts that function much like financial bank accounts.

According to the Bank Account Model of relationships, couples have an account that tracks their positive and negative interactions. Deposits are made when partners sacrifice self-interest to make the relationship a priority, show their love for each other, and pay attention to each other's interests. Withdrawals are made when partners are insensitive, inconsiderate, or put forth little or no effort to demonstrate the importance of the relationship. According to research, romantic partners who attend to and care for one another experience

the relationship more positively. For instance, if Jane casually mentions that she would like to learn more about wine and her husband John signs them up for a wine tasting class despite his own lack of interest in wine, John demonstrates that he cares about the things that matter to her and that he is putting the relationship first. Likewise, if Jane beams at John after hearing about his successful project at work, Jane's pride and adoration makes John feel loved and respected. Such actions lead to a deposit in the relational bank account. If, however, John allowed Jane's desire to learn about wine to slip by unnoticed or if Jane pointed out that John's success was not very important, withdrawals from the bank account would result.

Research demonstrates that a partner who supports the individual's ideal self (e.g., encouraging the individual to strive for a desired goal, finding ways to bring out the individual's desired qualities) leads to greater satisfaction in the relationship. For instance, if John considers himself shy but wants to become more outgoing, Jane might facilitate this by hosting a dinner party and bringing up topics of special interest for John to share with their guests. Over time, Jane's demonstrations of responsiveness and support can accumulate into a surplus or a credit in the relationship bank account. This abundance of positivity may lead individuals to think the best of their partners, seeing each other through rose-colored glasses. This generosity in perceiving the partner, called *positive sentiment override* by many researchers, may improve conflict resolution perhaps because partners are aware that they love and respect one another in spite of the current relationship difficulty and want

to maintain the relationship. If Jane blows up at John for no apparent reason, John may stifle a nasty retort because previous positive interactions have built credit in their relationship bank account. Instead, John makes an effort to understand Jane's frustration so that they can work through it. In this way, deposits to the bank account contribute to long-lasting, healthy relationships.

Support for the concept of positive sentiment override comes from research conducted by Sandra Murray and her colleagues. This work shows that when relationships are going well and partners are satisfied, they tend to see more positivity in their interaction than might otherwise be assumed. In other words, when credits accrue in the relationship bank account due to a large ratio of positive to negative interactions, partners perceive each other in ways that enhance their affection and commitment. This process is necessary given that romantic relationships inevitably have conflicts and other threats to relational stability. Credit in the relational account helps defend against the inevitable disagreements and insecurities, bolstering confidence in the integrity of one's partner.

Just as positive interactions add to the relationship bank account, negative interactions can produce negative balances, which may be detrimental for the relationship in the long run. If John tells Jane that her interest in wine is pointless or if Jane points out that John's work-related accomplishment will only cause his bosses to expect more from him, their hurtful acts will withdraw credit from the account. Deficits in the relationship bank account endanger the relationship because they leave the couple with less incentive to work out their current difficulty. When a new relational problem develops, such as Jane's unprovoked blow-up at John, partners have no reason to be compassionate and understanding. Instead, negativity may escalate; one partner's harmful conduct leads in turn to negativity from the other partner, and the problem goes unresolved. Furthermore, research has shown that negative interactions are relatively more influential than positive interactions. John Gottman and his colleagues observed that couples who have more than one negative interaction for every five positive interactions tend to be dissatisfied, creating distance in the relationship. In short, negatives may have greater impact on the relationship bank account than positives.

Individual differences may also affect the relationship bank account. Not all people are equally good at recognizing the deposits their partners have made. For example, those who are low in self-esteem or high in insecurity often perceive that their partners feel less positively about them than the partners actually report. One reason this may occur is that individuals with low self-esteem do not value themselves very highly and expect others to feel the same way. Individuals with low self-esteem may effectively make it difficult or impossible for their partners to build up credit in the relational bank account, while also interpreting neutral activity as withdrawals from the account. On the other hand, individuals high in agreeableness may be more prone to focus on their partner's deposits, paying less heed to withdrawals.

BARRIER FORCES TO RELATIONSHIP DISSOLUTION

This entry explores the social-psychological concept of barriers to ending a romantic relationship. Barriers are personal and social factors that make it more difficult to leave a relationship. The internal

kinds of barriers are mostly psychological in nature and include commitment, religious beliefs, self-identity, irretrievable personal investments, and children. The external kinds of barriers are more structural and draw their force from elements outside the relationship and from societal functions. Key external barriers include legal, financial, and social forces. Barriers are also considered a desirable developmental goal for couples seeking greater closeness and relationship stability. Recent societal-level changes have resulted in the weakening of some barrier forces.

Internal Psychological Barriers

Commitment and Obligations to the Marital Bond

Professing commitment to continuing the relationship is associated with greater future stability of premarital dating couples. Believing that divorce is morally wrong is also associated with greater commitment to the marriage and with staying married over longer periods of time. Conversely, past experiences with failure to uphold marital vows (either with one's own past divorce or with parental divorce) is linked to relationship instability.

Religious Beliefs

Many organized religions encourage marital union and do not support divorce. Thus, it is not surprising that the greater one's commitment to religion, the greater one's commitment is to maintaining a marriage. Those who report consistent regular participation in religious activities (such as attending church) often have lower rates of divorce than those who report no religious affiliation.

Self-Identity

Individuals in a romantic relationship are often attracted not only to each other but also to some aspects of the social roles they experience from being in the relationship. What it means to be a husband or wife can be a powerful source of pride and self-fulfillment. The more that one's sense of self-identity incorporates the relationship and the attributes of the partner, the more difficult it is to end the relationship.

Irretrievable Personal Investments

There are many ways that partners can make personal investments in their relationship. The more the two partners share their time and activities, the more they become emotionally linked together. Spending time together often generates greater positive emotional expressions and opportunities for personal self-disclosure. These kinds of intangible experiences can function as emotional investments made in the relationship that one cannot get back if the relationship were to end.

Children

Having a child is a significant barrier to marital relationship dissolution. The lowest rate of divorce is usually found during the first year after a baby is born. Conversely, couples with no children in the home have the highest divorce rate. If leaving the relationship with one's partner also entails changing or losing contact with one's children, it can be a force to keep the relationship alive. And yet having children in a relationship is by itself not a strong enough factor to prevent marital dissolution.

External Structural Barriers

Legal Barriers

The legal status of a marriage can serve as a barrier to relationship dissolution. The costs associated with obtaining a divorce are often far greater than the costs of dissolving other kinds of relationships lacking a formal legal status. Interestingly, it is often found that couples who live together but who do not marry tend to break up sooner than those who live together as a married couple.

Financial Barriers

There are often physical items of value that couples accumulate over time. Many marital couples eventually own a house or residence together and contribute to other major investments. The difficulty of dividing a couple's shared assets can be a restraining force to a breakup. There are also legal fees and other financial consequences of a divorce that can dilute the economic net value of each partner. Even more of a barrier to breakup is

the level of financial self-sufficiency each partner possesses. If one were to leave the relationship, could one financially afford to live independently of one's partner?

Social Barriers

Often the family and friends of one or both of the partners exert some form of influence on the relationship partners through their participation as members of the couples' shared social network. Not only do others offer emotional support to a couple, but also they can offer economic and practical assistance that is valued by the relationship partners. This kind of relational social support could be lessened or lost altogether if the couple were to break up.

The Positive Role of Barriers in Relationship Development

George Levinger's original conceptual model of marital dissolution examines the components involved in the decision to end a relationship. In his model, barriers only become relevant when one partner is dissatisfied with the relationship and feels that the alternatives to the relationship are better than what the current relationship provides. However, more recent perspectives on barriers include their role when one is still happy with the relationship. Having some barriers and making them stronger can demonstrate the growing intimacy between partners. Moving in together, getting engaged, marrying, buying a home, having children, and sharing friends and family are all factors that most couples see as positive events that represent a close and meaningful relationship. Thus, a desire for stronger barriers to dissolution can paradoxically—but accurately—be a sign of attraction to the relationship.

The Decline of Barriers in Modern Society

Past decades have witnessed gradual societal changes in almost all kinds of barriers. Concerning the internal barriers, surveys have shown declines in the belief in lifelong marital commitment, organized religious practices have decreased in popularity, and couples are having fewer children or none

at all. Concerning the external barriers, no-fault divorce laws have reduced legal barriers, the financial self-sufficiency barrier for many female partners has lessened due to the general economic progress made by women, and there is less social stigma attached to divorce and single parenting. The cumulative effect of these changes is twofold. For the happy couples, it makes it harder to build the barriers to dissolution they so desire. Conversely, for the unhappy couples, it makes it easier to actually break up because the costs to leave are lower. This shift toward weaker barriers may have contributed to the higher divorce rates experienced in the United States over the last 50 years.

BATTERERS

Battering refers to aggression perpetrated against an intimate relationship partner. Intimate partner violence (IPV) includes a heterogeneous set of behaviors. At one extreme is severe or frequent aggression that includes physical violence and may be accompanied by emotional abuse and sexual violence. Such violence is likely to cause fear and carries a high risk of injury for the partner. At the other extreme is mild violence that usually does

not occur frequently. Such aggression may be mutual and is assumed to emerge in the context of escalating conflict that is poorly controlled by both partners. This entry describes issues in conceptualizing, assessing, and treating IPV.

Assessment of IPV

In extreme cases, IPV may reach the attention of others through calls to domestic violence hotlines or law enforcement agencies. More typically, IPV is a private affair, occurring in the home with the only witnesses being the two partners and their children. Most researchers rely on partners' self-reports to identify the occurrence and extent of IPV. Many couples experiencing IPV do not label the behavior as violence, abuse, or battering. There are also potential problems of social desirability (e.g., Will someone admit to a socially sanctioned behavior such as violence?) and fear (e.g., Will a battered woman choose not to reveal her abuse out of fear of retaliatory violence from her partner?). Given such issues, some researchers rely on interviews, believing that clinical sensitivity is needed to detect violence.

The most widely used questionnaires are behavioral checklists (such as the Conflict Tactics Scale by Murray Straus and colleagues) that directly ask if particular behaviors have ever occurred, thus avoiding the problem of labeling such behaviors as violence or abuse. Such checklists ask whether each partner has engaged in a variety of behaviors (e.g., "pushed," "threatened with a knife or gun") in the context of relationship conflict. Other questionnaire measures of related constructs (e.g., emotional abuse, sexual abuse) may also be used to supplement questions about physical aggression. Regardless of method used (interview or questionnaires), partners should complete such measures independently to minimize concerns of one partner pressuring the other to answer in certain ways.

Partners may not agree on the occurrence, nature, or extent of violence. This discrepancy may reflect a trend for perpetrators to be less likely to report their own use of violence than victims to report their partner's aggression. In addition, for both perpetration and victimization, women are more likely to report IPV than men. Many experts assume that batterers in legal trouble or in

court-referred treatment are likely to minimize and deny their perpetration of violence. Given such factors, it is best to ask both partners about their own and their partner's relationship violence. Because the risks of failing to detect violence when it is occurring are generally considered greater than the risks of assuming violence is occurring when it may not be, the standard practice is to assume the occurrence of violence if either partner reports it.

Although behavioral checklists have proven reliable, they may not fully assess the context of the violence. For example, behavioral checklists consistently demonstrate that men and women engage in violence at similar prevalence rates, but such data do not allow one to equate male and female violence, as the questionnaires do not thoroughly assess consequences (e.g., women are more likely than men to be injured; fear of the partner) or context (e.g., initiation of violence to control the partner versus self-defense). Thus, many researchers and clinicians advocate that once violence is identified, more detailed questionnaires or interviews should be administered to better understand the qualitative aspects of the aggression that is occurring and its impact on both partners.

Correlates and Predictors of Battering

Societal Correlates

Feminists and battered women's advocates often focus on societal causes of IPV. They consider factors such as legal protection of women, indicators of gender inequality in resources and power, societal messages about male-to-female violence, and resources for female survivors of IPV. In the limited amount of social science research conducted from this perspective, such factors as the male's attitudes toward women and male peer support for IPV are examined.

Individual Differences

Social scientists often focus on personal variables and individual differences, considering the question of why some men engage in IPV, whereas others do not. The implicit assumption in such work is that batterers have some problem that exists within them that is activated in the context

of an intimate relationship. Another implicit assumption is that the risk of violence may be carried forward into new relationships so that a man may be at risk for perpetrating violence in multiple relationships with different women over time. Studies of such factors often involve comparing batterers to a comparison sample of nonviolent men on variables of interest or correlating levels of a variable of interest to the level of violence perpetrated among a group of study participants. More recent research is longitudinal in nature, examining earlier predictors of later onset or continuation of IPV.

In general, such work has demonstrated that batterers are more likely than nonviolent men to have grown up in a violent home, witnessed interparental violence, and been rejected or abused themselves as children. There are multiple theories to explain this intergenerational transmission of violence: genetics, social learning (e.g., men growing up in a violent home, never learning competent responses to interpersonal conflict and instead acquiring pro-aggression attitudes), and trauma (e.g., post-traumatic stress disorder leading to social information processing deficits). Outside of the home, batterers also may have been exposed to more community violence and may have associated with more deviant, delinquent, or aggressive peers while growing up.

Such research has also examined the notion that violent men have more psychological difficulties than nonviolent men. For example, violent men are at higher risk than nonviolent men for particular kinds of psychological problems, which include substance abuse, antisociality (e.g., criminal behavior), depression, and difficulties dealing with interpersonal relationships (e.g., attachment problems, dependency, jealousy). Other psychological factors, including some that might help to explain the link between psychopathology and the use of violence in a relationship, have also been studied. For example, relative to nonviolent men, batterers have been found to have fewer social skills. Thus, relative to a nonviolent man, a violent man is more likely to assume that his partner is acting with hostile intent but is less likely to be able to generate competent responses to hypothetical marital conflict situations. Violent men also report and express more anger and hostility, both toward others in general and toward their partner.

Dyadic Factors

Some argue that relationship violence may be less a product of individual problems and more a reflection of dyadic processes within particular relationships—that couple-level factors (e.g., poor communication, mismatched attachment styles) may help to explain violence. Research from this perspective may compare couples experiencing violence to nonviolent couples. For example, observation of couples discussing a relationship problem reveals that relative to nonviolent spouses, both partners in violent relationships engage in high levels of hostility (e.g., belligerence, contempt) and demanding and withdrawing behaviors. In addition, relationship satisfaction level is negatively related to risk for IPV. Violence levels are higher among cohabiting couples than among married couples, suggesting that relationship factors (e.g., lack of legal commitment and related jealousy) are related to violence among cohabiting couples.

This perspective implicitly assumes that the causes of relationship violence lie within the dyadic situation and that an individual may be violent in one relationship but not in others. A criticism of this perspective is that by examining the potential role of both partners in violent episodes, battered women may be blamed for their own victimization, and differences in male and female violence will be misunderstood.

Multivariate Approaches and Batterer Typologies

Increasingly, theorists realize that all of these approaches have merit, and newer theoretical models of battering acknowledge societal, individual, dyadic, and situational or contextual factors as all playing a role in IPV. Different types of violence may be differentially related to differing causes and correlates. For example, more severe violence may be driven primarily by individual issues (a batterer will be violent toward many romantic partners, given his own problems), whereas less severe and mutual violence may be driven by dyadic factors (for any individual, low levels of violence may emerge in the context of a problematic relationship with a particular partner but may not systematically characterize future relationships). More research is needed to test such ideas.

Treatment of IPV

In the past 20 years, increasing concern about IPV and the widespread adoption of pro-arrest policies (i.e., police being encouraged to make an arrest when intervening in cases of domestic violence) have led to the establishment of IPV treatment programs. The use of couple therapy for violent relationships is quite controversial and covered in another entry. In addition, programs for battered women were developed through earlier grassroots efforts and, although offered to women, are not mandated by courts or police. Among available programs for male batterers, the most common intervention involves group psychoeducational programs.

Historically, there have been two major theoretical approaches to such programs. One is derived from a feminist perspective. Such programs emphasize male violence as only one problematic outcome from male attitudes toward women and ask men to examine the multiple other ways in which they abuse and control women. The other approach is behavioral-cognitive. These programs focus on changing reinforcers and on building skills to help men decrease their use of violence (e.g., anger management, time-outs, communication skills). Many existing batterer programs combine both approaches. In addition, both approaches share fundamental elements, for example, helping men accept responsibility for their violence and agree to become nonviolent.

Whether such programs are effective is a heavily debated issue. Major studies, reviews, and recent meta-analyses suggest that these programs do not work. The good news is that as many as two thirds of men in such programs stop being violent, at least over the course of the relatively short-term follow-ups used in these studies. The bad news is that this rate of violence desistance is not significantly different from the rate of violence cessation among men arrested but not sent to therapy or among men arrested but given other interventions (e.g., intensive probation supervision). Thus, it is not clear that batterer psychoeducational programs add to more basic criminal and legal interventions. Because the number of high-quality studies of batterer treatment outcome is limited, many argue that it would be premature to abandon such programs.

Such findings have led clinicians and researchers to consider how interventions for batterers can be improved. Indeed, this juncture in the field seems to be an opportunity for generating new approaches to treating batterers, including treatment of related substance abuse issues, the development of culturally sensitive interventions, using motivational interviewing approaches to help batterers decide to change, and using individual therapy (rather than group interventions) to tailor treatment to the various needs of batterers.

BEHAVIORAL COUPLE THERAPY

Behavioral Couple Therapy (BCT) has been used with married, cohabiting, and dating heterosexual and homosexual couples presenting with relationship dissatisfaction and a range of life experiences (e.g., parenting difficulties or illness) that may have contributed to relationship problems. The approach originated with published case studies by Robert Weiss, Gerald Patterson, and Richard Stuart. In 1979, Neil Jacobson and Gayla Margolin published a book that is recognized as the treatment manual for BCT. As the first empirically supported couple therapy, BCT has now been evaluated in five countries and frequently serves as the comparison treatment to beat in empirical investigations of other treatment approaches. This entry describes defining characteristics, implementation, supporting evidence, and new directions in BCT.

Defining Characteristics

BCT is distinct from other couple interventions because of its primary focus on observable relationship events and its grounding in social learning principles. BCT seeks to alleviate relationship distress by increasing the range and frequency of positive relationship events and reducing aversive relationship events. A beneficial ratio of relationship rewards to costs is considered an important condition for relationship satisfaction. BCT also reduces relationship distress through teaching relationship skills, particularly related to effective communication and problem solving. With relationship disagreements anticipated in all intimate relationships, partners need skills to resolve their differences before disagreements turn into serious conflicts or lead to emotional withdrawal.

The social learning perspective on couple relationships assumes that the behavior of each partner is shaped by environmental events, particularly

those coming from the other partner. The partners thus have important influences on one another's behavior and relationship satisfaction. Identifying the ways that partners contribute to the behaviors that they find troublesome is accomplished through functional analysis—that is, the thorough examination of antecedents and consequences of important behaviors. It is then possible to develop hypotheses about how to alter the problem behavior through changes in these conditions. BCT steadfastly focuses on uniform and specific treatment components, that is, behavioral exchange and communication training, but the issues addressed and interactions modified are informed by a couple's individualized functional analysis.

Implementation

Behavioral exchange interventions often start with infusions of pleasing behaviors, for example, through homework assignments such as expressing appreciation on a daily basis, planning a special evening for the partner, engaging in a mutually enjoyable activity, or taking over some burdensome responsibility from the partner. The therapist assigns these activities after carefully assessing what partners find lacking in their current relationship (e.g., appreciation) and what the couple is capable of doing without resorting to conflict or criticism. These activities can be powerful reminders of each partner's ability to have a positive impact on the other and can serve as incentives for working on more difficult relationship topics.

Communication and problem-solving training generally includes two sets of skills—one to foster understanding and the other to facilitate change. Empathy and listening skills reduce negative interactions by limiting the speaker to short, clear statements and by having the listener restate the content or reflect the emotional message. The listener's demonstration of understanding builds rapport and circumvents disagreements due to misinterpretation.

Once a problem is understood, a decision can be made about whether to generate a plan for change. Problem solving follows a structured format that begins with defining the problem in a way that is nonblaming and specific and acknowledges one's own contribution. The partners brainstorm solutions to a particular problem, generating as

many solutions as possible without concern for the quality or feasibility of solutions. With all solutions written down, partners then rate and discuss each proposed idea until one or more solutions emerge as a potential option. Jacobson and Margolin provide a manual for couples that details guidelines for effective problem solving.

Supporting Evidence

The American Psychological Association's Division 12 Society of Clinical Psychology designates BCT as an empirically supported treatment for relationship distress. BCT is significantly more effective than receiving no treatment, according to a 2005 meta-analysis by William Shadish and Scott Baldwin that examined 30 studies. Andrew Christensen and colleagues recently compared BCT and Integrative Behavioral Couple Therapy and did not show the superiority of either approach; however, they did find different patterns of improvement, with positive effects from BCT peaking earlier and then plateauing.

New Directions

Despite BCT's effectiveness, Jacobson and colleagues highlight that there is room for more clinically meaningful change—only approximately 50 percent to 60 percent of couples improve with BCT and about one third of improved couples experience relapse over the next 2 years. Statistics such as these have spurred transformations of BCT. One wave of changes by Donald Baucom and Norman Epstein recognized the need for attention to cognitive processes (interpretations and evaluations of behaviors) and affective processes (experiencing and expressing emotions, and regulating emotional responses). Christensen and Jacobson developed integrative behavior couple therapy to incorporate acceptance interventions with the change-promoting interventions used in BCT. Another enhancement is adaptation of BCT for individual psychiatric problems, such as alcoholism and depression. Timothy O'Farrell and William Fals-Stewart, for example, provide a comprehensive guide for BCT for individuals with alcohol and substance abuse problems and for their intimate partners. As the field of couple

therapy advances, BCT remains a strong component of these new directions.

BEHAVIORAL PARENT TRAINING

The concept of behavioral parent training, which can be traced back to the early 1960s, refers to the teaching and deployment of parents as therapeutic agents in the treatment of troubled children or of children in need of special assistance. Psychologists and other mental health professionals realized that children's social, emotional, and behavioral problems were not effectively addressed by meeting with a therapist for 1 or 2 hours per week. Children's behavior is heavily influenced by the immediate environment around them, including interactions with parents, siblings, peers, teachers, and others. The idea behind parenting training is that parents are often in a better position than anyone else to alter the environmental conditions and situations impinging on their children's behavior and thereby can promote better child adjustment. Training a parent to be a "therapist" of sorts is a potentially more effective treatment

strategy than one-on-one professional counseling or therapy with a young child in part because of the countless hours each week that children spend with their parents and because talking with a child may not in and of itself change the child's behavior. This entry addresses theoretical foundations of behavioral parent training, summarizes early approaches to parent training, and then describes more recent parent-training interventions.

Theoretical Foundations

Behavioral parent training is grounded in psychological principles of learning, which are readily accessible by parents, teachers, and others who interact with children. The field of behavioral learning has produced a complex body of knowledge about the moment-to-moment interactions between individuals and their environments, which affect observed behavior. Learning principles have been translated into methods of behavior change that professionals could teach to parents and apply to a variety of child problems. Basically, parenting-training methods are used to promote healthy and positive child behaviors, to replace or prevent unhealthy or problematic behaviors, and to teach specific skills with a variety of child populations.

Early Forms of Parent Training

The first forays into behavioral parent training focused on discrete child problems such as frequent and destructive tantrums or abnormally fearful responses. This work with individual parents was part of the budding field of applied behavior analysis in which children's behavior was observed in social and environmental contexts. The observations were part of what is called *functional analysis of behavior* to determine which environmental cues and events were maintaining or exacerbating the problematic behavior. A parent participating in behavioral parent training would first keep track of specific events and child behavior, as well as their own behavior, and use the records to help plan the next steps. Parents learned specific child-management techniques that they applied at home while they continued to keep track of progress.

One guiding principle for behavioral parent training is that specific occurrences of behavior are affected by the immediate environmental consequences or events. For parents this means that child behaviors that result in immediate attention from people tend to get strengthened or repeated. For example, behaviors such as tantrums or showing off, which are attempts to gain an audience, get rewarded or "paid off" in a sense by the responses of others. In behavioral parenting training, parents first learn how to observe these kinds of contingent relationships between child behavior and social-environmental response and then how to alter the contingencies for more positive outcomes. For example, parents might be encouraged momentarily to ignore attention-seeking behaviors or to remove their child from situations in which the child could elicit attention from others.

A second guiding principle in behavioral parent training is the concept of differential reinforcement of other behavior (DRO). With DRO, parents and other significant individuals in a child's world try to respond consistently and positively to constructive behaviors that are incompatible with problematic behavior that needs to be diminished. For example, speaking nicely to siblings and sharing toys and activities with others are behaviors that are incompatible with fighting and bossy behavior and are thus good candidates for the use of DRO by parents. Parents are taught to reinforce such behaviors by commenting positively to the child, publicly recording such instances on a recognition chart, or following episodes of these behaviors with immediate positive consequences (e.g., fun activity, a treat, or another pleasant event).

Other common elements of behavioral parent training include giving clear instructions, using successive approximations to teach or "shape" new child skills, prompting where necessary, and "fading the prompt" to encourage self-reliance in children.

Some of the earliest forms of behavioral parent training focused on the addressing of single problem behaviors in children such as tantrums, mealtime difficulties, fighting with other children, and lack of cooperation with parental instructions. Other early efforts focused on the specific needs of special populations such as developmental disabilities and autism. Behavioral parent training, which augmented other intensive interventions for

these populations, addressed the promotion of basic skills such as speech, social interaction, and self-care, and the reduction of problem behaviors such as self-destructive and self-stimulatory acts.

More Recent Forms of Parent Training

Over a 40-year period, behavioral parent training has evolved into a more sophisticated array of parenting interventions that are useful in a number of contexts. Some of the more recent forms of parent training go beyond learning theory and draw on a variety of practical theories about parental cognitions and beliefs, child development, family dynamics, and relationships. The newer versions of behavioral parenting training address a wider array of problems, involve more goal setting and assessment by parents, make use of a greater variety of delivery formats (parent groups, individual family sessions, telephone consultation, video-DVD instruction), and take a more comprehensive approach to family functioning and intervention.

Behavioral parenting training programs and interventions that have proven to be effective have several attributes in common:

- Action focused: More than just talk, parents actually do things during the program and carry out activities at home.
- Problem-solving oriented: Specific challenges faced by parents are addressed; they work toward solutions to the identified problems and build on child and family strengths.
- Specific parenting strategies: Strategies are specific, concrete, and practical so that parents can add to their repertoire of parenting practices.
- Collaborative goal setting: Parents set the child and family goals; the intervention professional provides guidance but works collaboratively.
- Consultative rather than prescriptive: Intervention professional is a consultant rather than a “boss.”
- Adoption of positive frame: Program is nonjudgmental about the parent, looks to build on parent and child competencies, emphasizes expanding positive child behaviors to displace problematic behaviors, and is optimistic, encouraging, and patient in its delivery.

Although these attributes reflect considerable commonality across programs and interventions, there is also some variability in approach by different behavioral parent training programs. Two well-known programs, each with impressive evidence of effectiveness, illustrate some of the variation. The first is Parent-Child Interaction Therapy (PCIT), which was developed by Sheila Eyberg and colleagues at the University of Florida. PCIT is a clinic-based therapy program for parents of children ages 3 through 8 with oppositional defiant disorder and related problems. In PCIT, parents learn how to become more positive in the use of praise and differential attending (responding to desirable child behaviors and ignoring undesirable behaviors) and in the avoidance of counterproductive criticism. Parents also learn how to manage misconduct situations better. From behind a one-way mirror, therapists watch parents interacting with children and coach them through the use of electronic communications (e.g., bug-in-the-ear, a receiver that is put in the parent’s ear into which the therapist provides instructions and tips so that the parent can hear it, but the kid cannot). Parents participating in PCIT receive intensive practice and coaching in the clinic and then carry out specific procedures at home with their children. PCIT offers a cogent method of helping parents who are faced with challenging child behaviors.

For example, PCIT has all parents go through the same two procedures no matter what their concerns are. The first procedure is a play situation in which the parents orient towards child-directed activity. During the child-directed procedure, parents cannot make requests or ask questions but instead must focus solely on attending to and describing-praising any nonnegative behaviors on the part of the child. The second procedure is a parent-directed situation in which the parent is seeking to have the child do something the parent is requesting. This parent-directed activity provides an opportunity for the therapist to coach the parent in how to administer clear instructions and includes calm, straightforward steps for handling noncompliance and promoting cooperation.

A very different approach to parenting intervention, which builds on behavioral parent training, can be found in the Triple P—Positive Parenting Program. Developed by Matthew Sanders and colleagues at the University of Queensland, Triple P is

actually a system or suite of parenting programs organized in multiple levels of increasing intensity to match the varying needs of families. Triple P is applicable to both the prevention and the treatment of children with social, emotional, and behavioral problems. This approach was designed for reaching the larger population of parents via many settings (e.g., schools, health centers, clinics, home visiting, daycare centers, preschools, churches, community centers) and formats (e.g., brief consultation, parent groups, intensive intervention with an individual family, mass media). Triple P covers a wide variety of common developmental and behavioral topics (e.g., mealtime, bedtime, tantrums, fears, separation anxiety, homework, etc.) and more serious problems (e.g., aggression-violence, bedwetting, bullying, depression). The main interventions within the Triple P system focus on parents of children birth to 12 years throughout the population, and other variants of Triple P are intended for parents of young children with developmental disabilities, parents who are at elevated risk to engage in abusive parenting, and parents of teenagers.

For example, Triple P parent training is organized around the specific goals that parents wish to achieve with their children. Together, the service provider and the parent figure out what is maintaining any problem behaviors or what is interfering with healthy child development and then craft a parenting strategy. The Triple P provider exposes the parent to a broad array of evidence-based parenting strategies and then helps the parent choose the strategy or strategies that fit the parent's style preference, the child's developmental level, and the particulars of the presenting situation.

Variants of behavioral parent training have been applied to many areas and problems including but not limited to developmental disorders (e.g., autism, Asperger syndrome, Down syndrome), childhood aggression, attention-deficit hyperactivity disorder, bedwetting, adolescent substance abuse, childhood anxiety problems, school refusal, early-childhood preparation for school, families going through divorce, families dealing with bereavement, chronically ill children, parents who have engaged in child abuse, foster parent preparation, and issues faced by newly formed stepfamilies. In the area of child mental health treatment, behavioral parent training represents

the single most successful modality in terms of efficacy and benefits. Overall, behavioral parent training has made considerable strides in 50 years to prove useful to many families across a wide variety of settings and contexts.

BELIEFS, DESTINY VERSUS GROWTH

People often bring their own assumptions and beliefs about how relationships function when they enter a romantic relationship. What people believe about relationships guides their goals and motivations in developing relationships. Carol Dweck distinguished between the belief that attributes such as intelligence are fixed versus flexible.

The concept of destiny and growth beliefs is derived from applying this more general distinction to the specific case of romantic relationships. Destiny and growth beliefs reflect assumptions about how one can initiate and maintain relationships. Destiny belief concerns the stability of one's early impressions about relationships and reflects the belief that potential relationship partners are either compatible or not. Independently, growth belief concerns the maintenance and development of relationships and reflects the belief that relationships improve with effort and that challenges can be overcome. Together, these beliefs guide how people orient toward and interpret events as the relationship develops. These beliefs help guide how events and situations are interpreted within one's relationship.

People who believe more strongly in destiny attempt to determine the compatibility of their partner and the future potential of the relationship based on minimal information. They place high value on determining whether a relationship is meant to be and tend to diagnose the potential of the relationship based on specific events. Indeed, relationship survival is linked to initial satisfaction for those who believe more strongly in destiny. When those who hold stronger destiny beliefs initially feel more satisfied, their relationships last particularly long; whereas when they initially feel less satisfied, their relationships end quickly. A stronger belief in destiny is associated with a more judgmental approach to relationships so that flaws of character or initial awkwardness are thought to be permanent. Thus, when problems arise, those higher in destiny belief are more likely to view the problem as a sign that the relationship is not meant to be. Indeed, destiny belief tends to be associated with disengaging from the relationship when there is a problem.

Those who believe more strongly in growth are primarily interested in developing the relationship and believe that relationships can be improved with effort and maintenance. They believe that successful relationships are developed by conquering obstacles and growing closer. Indeed, growth belief predicts fewer one-night stands during the first month of college and dating a particular person for a longer period of time. Moreover, when there are problems, growth belief predicts a greater number of attempts to maintain the relationship by using a variety of coping strategies.

Independence of Destiny and Growth

Destiny and growth beliefs tend to be independent so that individuals can endorse both or neither, as well as the typical extreme combinations (higher on one and lower on the other). It is fairly common for individuals to believe that fate brings potential partners together but that every relationship takes work to maintain. Both destiny and growth beliefs can be optimistic and hopeful about romance, and both beliefs are positively related to more traditional romantic beliefs.

The independence of destiny and growth beliefs suggests that each dimension can contribute uniquely to predicting and explaining relationship perceptions, cognitions, and behaviors. It also suggests, however, that particular combinations of destiny and growth may be especially relevant. An evaluation orientation captures those with the combination of a higher destiny belief and a lower growth belief. These people believe that relationships can be easily diagnosed and evaluated but that they cannot be considerably improved. When evaluating, a person's goal becomes the diagnosis of one's partner and relationship in an effort to determine whether the relationship would seem to have immediate promise without attempting to improve the relationship. In contrast, a cultivation orientation captures those with the combination of a higher growth belief and a lower destiny belief. These people believe that relationships evolve through development, confrontation, and efforts to maintain and improve the relationship, and they are less focused on diagnosing the future potential of relationships. When cultivating, one's goal becomes the development and maintenance of the relationship without inferring grand meaning from otherwise minor differences.

Loving One's Partner, Flaws and All

Destiny and growth beliefs have been found to moderate or qualify several important processes. For example, viewing one's partner optimistically (e.g., through rose-colored glasses) is not necessary when one is higher in growth and lower in destiny beliefs. When one has this cultivation orientation, differences and disagreements that would otherwise seem threatening are instead viewed as

challenges and opportunities to better understand one's partner and to develop the relationship. Thus, when one has a cultivation orientation, the perception that a partner falls short of one's ideal is not linked to feeling less happy with the relationship. Similarly, whereas disagreements are often followed by feeling less committed to relationships, this is less so when one is higher in growth belief. Further, during disagreements, whereas an evaluation orientation tends to produce more hostility, a cultivation orientation tends to produce more positivity.

BELIEFS ABOUT RELATIONSHIPS

Beliefs about relationships are an important guide and organizing principle for social lives. They are mental schemas, like images, representations, or scripts that are usually in unconscious thoughts. They influence what people expect from certain types of relationships in subtle ways. For example, relationship beliefs help people organize their relationships into types, such as “just friends” rather

than “dating partners” based on sexual attraction and/or involvement. They also tell people how to act in relationships and what to expect from others in those relationships. For example, people expect that siblings may argue sometimes but be there to support each other in times of stress. People expect close friends to keep their secrets and to never speak badly about them behind their backs. People expect a store clerk to say, “Have a nice day” as a routine comment when they leave the store but would be surprised (and perhaps hurt) if a close friend uttered the same words at the end of a deeply personal conversation. In sum, relationship beliefs help people categorize their relationships, guide their behaviors, tell them what to expect from others, and even explain the emotions they sometimes have when their expectations are not met.

Of particular interest to scholars who study human relationships are the beliefs people hold about romantic relationships. These relationships are a special category of social relationships because, unlike family relationships, they are voluntary and self-selected. Also, unlike friendships, people tend to have just one, exclusive romantic relationship. In fact, the dating process is guided by assumptions regarding who would be an ideal mate if people plan to marry and whether the relationship people have measures up to the standards they hold for a romantic relationship. When a partner or a relationship does not measure up to the ideals people hold, they may change their expectations, change the relationship definition (e.g., let's just be friends), or terminate the relationship. If a dating relationship leads to marriage, scholars report that some relationship beliefs facilitate a stable and satisfying marriage, while other beliefs lead to problematic communication patterns and relational dissatisfaction.

The goal of this entry is to describe more specifically the relationship beliefs associated with romantic relationships, both dating relationships and marriage. This entry will present two approaches to romantic relationship beliefs and summarize the findings from research done in these areas. The first approach conceptualizes relationship beliefs as an ideology about the nature of romantic relationships in general—a sort of romantic ideal of true love. The second approach, which is influenced by the experiences of marriage

counselors who work with distressed couples, focuses on relationship beliefs that are unrealistic and on dysfunctional expectations and standards for romantic relationships.

Romantic Ideology

Scholars working in this perspective view relationship beliefs as preexisting expectations about romantic relationships. Although seldom present in conscious awareness, they provide the ideal against which past, present, and potential relationships are compared. When romantic relationships are consistent with these expectations, positive emotions such as liking and love are experienced; when they are inconsistent, negative emotions such as disappointment and sadness are experienced. Although these beliefs may change somewhat over time, they are actually developed very early in childhood as people observe their parents' relationship, see depictions in movies, and watch television dramas and sitcoms that present romantic relationships.

Scholars differ somewhat on the specific factors that constitute these belief structures. Raymond Knee proposes two dimensions: *destiny* and *growth*. The destiny dimension assesses the extent to which people agree with the general idea that potential partners are either meant for each other or not. It is measured by asking people to rate how much they agree or disagree with such statements as, "Potential relationship partners are either compatible or they are not." The growth dimension assesses the extent to which people agree with the general idea that successful relationships are developed by overcoming the obstacles that are likely to arise. It is measured by asking people to rate how much they agree or disagree with such statements as, "A successful relationship evolves through hard work and resolution of incompatibilities." As people might expect, research indicates that when people believe successful relationships must be developed through hard work (growth), they tend to have longer and more satisfying relationships, fewer one-night stands, and more productive responses to conflict (e.g., feel comfortable and not hostile after they discuss differences in how they view the relationship). Thus, it appears that belief in growth (rather than in destiny) facilitates a

couple's willingness to acknowledge challenges to the relationship and to deal with them through open communication rather than to avoid them or simply dissolve the relationship.

Other scholars identify somewhat different dimensions constituting relationship beliefs, but they are theoretically consistent with growth and destiny beliefs. The Romantic Beliefs Scale, constructed by Susan Sprecher and Sandra Metts, provides evidence for four types of romantic beliefs: *Love Finds a Way* (believing that love makes it possible to overcome all obstacles in a relationship), *One and Only* (believing that there is only one true love for every person and to be truly in love is to be in love forever), *Idealization* (believing that one's partner and relationship will be perfect when truly in love), and *Love at First Sight* (believing that it is possible to fall in love almost immediately when the right person comes along). Research using these four dimensions indicates that romantic beliefs are positively associated with love, satisfaction, and commitment in romantic relationships. That is, the more "romantic" people are, the more they love their partner, are satisfied in the relationship, and want to stay committed to the relationship over time. In addition, and perhaps surprising to some readers, men typically score higher on total romantic beliefs and especially on Idealization compared to women. Some scholars suggest that this strong belief in the romantic ideal partially explains why some men report greater distress when imagining that a partner had committed emotional infidelity compared to imagining that a partner had committed a sexual infidelity.

Research employing the Romantic Beliefs Scale also confirms the framing effect of culture on romantic ideology. For example, one study found that American and Russian respondents endorsed romantic beliefs more strongly than did Japanese respondents. Also, a comparison of Chinese and North American samples indicated that the Chinese respondents scored higher on the combined Romantic Beliefs Scale as well as on two specific dimensions: One and Only and Idealization. In addition, within the American culture, research indicates that differences exist among ethnic groups. In a comparison of European-American and African-American samples, researchers found that the African-American respondents viewed

Idealization and One and Only as the same belief (i.e., both combined into a dimension labeled *One Perfect Love*) rather than as two separate beliefs.

A third model of romantic relationship beliefs has been developed and tested by Garth Fletcher and his colleagues. The conceptualization of romantic ideology is similar to the perspectives described above but includes somewhat different dimensions than the previous scales. These differences stem, in part, from its origin. The Relationship Beliefs Scale was derived from the elements that dating and married adults listed in response to the question, "What would contribute to a successful intimate relationship?" These elements included various content areas (e.g., communication, sex, and friends) that respondents believed would influence both the quality (e.g., happiness and satisfaction) and process (e.g., conflict and stability) of intimate sexual relationships. Four dimensions emerged from these lists. *Intimacy* focuses on beliefs about interpersonal attitudes and interaction that facilitate closeness (e.g., trust, respect, communication, support, acceptance, love, friendship, and compromise). *External Factors* focuses on beliefs related to the importance of issues or problems external to the relationship (e.g., important others, finances, commonality, and children). *Passion* focuses on elements of the sexual relationship and its vitality (e.g., the importance of satisfying sex). Finally, *Individuality* focuses on independence and equity (e.g., rights to personal privacy).

Research using the Relationship Beliefs Scale reveals that these romantic beliefs are not directly related to relationship satisfaction but that they are indirectly related. That is, when people felt strongly, for example, that good relationships require respect, communication, and compromise (i.e., Intimacy), they were more likely to listen to their partners, express their feelings, provide support when their partners needed it, and made sacrifices for the sake of their partner or the relationship. These behaviors, then, influenced the positive feelings of the partner, feelings that enhanced the quality of the relationship, which enhanced the couple's overall level of satisfaction. Interestingly, as will be evident below, a similar pattern occurs in reverse when romantic partners express strong agreement with dysfunctional relationship beliefs.

Dysfunctional Relationship Beliefs

The second general approach to beliefs about relationships stems initially from an interest in the contributions that dysfunctional beliefs play in marital distress. The most widely used measure in this area, the Relationship Belief Inventory (RBI), was developed by Roy Eidelson and Norman Epstein based on surveys completed by marital therapists who described attitudes and expectations they felt contributed to marital problems. The RBI consists of five belief domains: *Disagreement Is Destructive* (e.g., "If your partner expresses disagreement with your ideas, s/he probably does not think highly of you"), *Mindreading Is Expected* (e.g., "A partner should know what you are thinking or feeling without you having to tell him/her"), *Partners Cannot Change* (e.g., "Partners cannot change themselves; relationship/damages done early in a relationship probably cannot be reversed"), *Sexual Perfectionism* (e.g., "I get upset if I think I have not completely satisfied my partner sexually"), and the *Sexes Are Different* (e.g., "There are differences between males' and females' personalities and relationship needs; you can't really understand someone of the opposite sex").

Research has confirmed the utility of the RBI for clinicians and relationship researchers. However, before reviewing that research, it is important to note that scholars have also critiqued the RBI and offered suggestions for improvement. For example, research has indicated that the Sexes are Different dimension is actually two categories rather than one. These two categories represent (1) differences between men and women in their needs and (2) the difficulty (even impossibility) in understanding the opposite sex. In addition, because the original scale tends to blend relationship-specific beliefs (e.g., "I cannot accept it when my partner disagrees with me") with more abstract cognitions about the way relationships in general should be (e.g., "Partners should sense each other's moods"), a revised version of the RBI has been introduced to include parallel sets of relationship-specific and relationship-general dysfunctional beliefs.

Despite these concerns, research using the original and revised versions of the RBI indicates logical connections between dysfunctional beliefs and relationship maladjustment, particularly those

aspects related to problematic communication. For example, to the extent that young adults in dating couples believe that disagreement is destructive and that partners cannot change, they are more likely to respond to relational problems by simply leaving the relationship or avoiding important issues rather than openly discussing them. In married couples, spouses who endorse higher levels of dysfunctional beliefs are more likely to exhibit destructive communication behavior (e.g., interrupting, getting off topic, blaming) during conflict interactions. Moreover, husbands who endorse dysfunctional beliefs are even more likely than their wives to reciprocate negative behaviors rather than to ignore them. Although married couples are not as likely as dating couples to break up, as might be expected, these patterns do contribute to lower levels of relational satisfaction. There seems to be a prevailing sense of futility for those couples who believe that disagreement is bad, that they can never understand each other, and that they cannot change anyway.

Research has also examined how dysfunctional relationship beliefs fit within larger models of relationship stability such as with the Investment Model. According to the Investment Model, people feel greater satisfaction in their relationships when they receive more rewards than costs and when the relationship is better than their previous ones or other people's relationships (i.e., closer to their ideal). Furthermore, when they have made investments (of time, money, or other resources) into the relationship and when they do not think they have another alternative (e.g., being alone or finding another partner), they are highly committed to the relationship and it is likely to be stable and enduring. Using this model along with measures of relationship beliefs, scholars have found that when people believe strongly that the sexes are different in emotional, psychological, and relational needs and that men and women can never fully understand each other, they are less willing to commit fully to a relationship. This pattern is especially true for women. However, the lower commitment is not the direct result of dysfunctional relationship beliefs. Rather, women who believe the sexes are inherently different perceive greater costs than rewards in their relationships, are more likely to consider possible alternatives to their relationship, and are less likely to feel that their current relationship matches

up to an ideal comparison level. As a result, these women are less likely to feel satisfied, less likely to invest in the relationship, and therefore, feel less commitment to their partner or the relationship.

Finally, research indicates that in much the same way that romantic ideals are shaped by culture, so too are dysfunctional relationship beliefs. In a comparison of samples from three countries—Georgia, Hungary, and Russia—dysfunctional beliefs were most strongly endorsed in Georgia and least in Hungary. In all three countries, dysfunctional beliefs were associated with lower relationship quality, although the strength of the association varied by country. In Hungary, the most individualistic culture, the association was very high, and the Hungarian sample was less likely to believe that the Sexes are Different and that Disagreement is Destructive, but they were also more willing to believe that Mindreading is Expected.

It is interesting to speculate whether the exporting of Western popular culture may eventually influence other cultural views of romantic relationships. American samples indicate a positive correlation between media exposure (e.g., men's and women's magazines, tabloids, television sitcoms and dramas, movies, romance novels, and popular music) and unrealistic relationship beliefs. For example, listening to rock music and reading psychology self-help books are associated with Sexual Perfectionism. In addition, high television viewing is associated with the belief that the Sexes are Different, and heavy soap-opera viewing is associated with the belief that Mindreading is Expected.

Although dysfunctional relational beliefs may eventually lead to disappointment and frustration for people actually involved in maintaining romantic relationships, this does not mean that all irrational beliefs about what is possible for a romantic relationship are necessarily dysfunctional. As Jeffery DeBord and John Romans argue, some relationship beliefs that appear to be irrational can be advantageous if they motivate efforts to bring one's relationship as close as possible to the ideal. In other words, relationship beliefs (even when they seem unrealistic) can be used as an ideal standard or goal that both partners agree is worth trying to achieve rather than being used as a standard that means failure if not consistently or fully met. These researchers developed the Relationship Belief Questionnaire (RBQ) to measure the types of

irrational beliefs that people might hold regarding their current relationship: (a) "We should be completely open and honest with each other at all times," (b) "We should be able to read each other's minds," (c) "We should do everything together," (d) "We should be able to meet all of each other's needs," (e) "We should be willing and able to change for each other," (f) "Things should always be perfect between us," (g) "Good relationships should be easy to maintain," (h) "One can never be complete without being involved in a romantic relationship," and (i) "Romantic idealism." Responses on the RBQ from married and cohabiting couples indicate that these irrational beliefs about one's own current relationship (relationship-specific beliefs) are associated with higher levels of relationship satisfaction and adjustment. Although well-adjusted couples may simply be more likely to believe that these goals are attainable in their relationship, it is also possible that these belief systems motivate positive relationship behaviors that are then reciprocated by partner. In this sense, irrational beliefs act as a type of positive illusion that allows partners to interpret each other's behaviors in the best possible light and to respond to problems constructively.

Summary

Past research has identified a variety of beliefs about romantic relationships and has documented how these beliefs influence individuals and their relationships. Thus far, scholars have focused on two major approaches to beliefs about relationships. The first perspective examines beliefs that constitute the romantic ideal, while the second approach examines beliefs about what relationships in general and one's own relationship must be. Although some beliefs about relationships are unrealistic and even dysfunctional, research shows that some degree of idealistic expectations for romantic relationships may motivate individuals to strive to bring their relationships as close as possible to their idea of the "perfect" relationship.

Directions for Future Research

A useful direction for future research is to examine tensions in beliefs about relationships through the

lens of Dialectical Theory. That is, scholars should examine how individuals and couples manage the competing and contradicting tensions between their realistic and emergent relationship expectations and their idealized and preexisting expectations. As with any dialectical tension (e.g., openness vs. closedness, novelty vs. predictability), the satisfied couple somehow finds a way to manage these contradictions. The understanding of relationship quality and stability would be enhanced by a fuller understanding of this process.

BELONGING, NEED FOR

The need for belonging (also called the need to belong, belongingness motivation, or the need for relatedness) refers to the fundamental and universal human motivation to develop and maintain stable and caring interpersonal relationships. This notion has deep roots—Aristotle, John Locke, and Charles Darwin, among many others, argued that humans are social animals. More recently, social scientists have collected and reviewed substantial evidence supporting the fundamental nature of belongingness in humans. This entry discusses the nature of the need for belonging, why it qualifies as a fundamental motivation or basic psychological need, and consequences of satisfying and thwarting the need.

Evidence for the Need for Belonging

Several theoretical approaches have addressed the fact that humans are motivated to form and maintain social connections. Many early approaches did not afford any special status to belongingness motives, listing them among sometimes lengthy catalogs of other motives. In contrast, more recent approaches have argued that belongingness is not merely one motive among many, but rather that it is a fundamental motivation and a basic psychological need. Although definitions of psychological need differ between theories, there is wide agreement on several criteria.

Basic needs are believed to involve strong emotional responses that alert an individual when a need is not being met and motivate behavior to meet the need. In addition, basic psychological needs are believed to lead more generally to overall well-being when satisfied and to severe negative

consequences (beyond momentary psychological distress) when thwarted. Some theories argue that basic psychological needs are essential for optimal functioning, just as certain nutrients are necessary for the optimal growth of plants and animals. Consistent with these theories, research shows that fulfillment of the need for belonging is associated with greater subjective well-being, positive affect, life satisfaction, and physical health. Even on a day-to-day basis, individuals tend to report greater well-being on days characterized by close interactions with others. Conversely, when the need for belonging is blocked through rejection, isolation, loss, or unsatisfying social relationships, individuals are likely to experience greater negative emotions such as anxiety, sadness, and hurt feelings. Some negative emotions, such as shame, guilt, loneliness, and embarrassment, seem to be uniquely social in nature and may have evolved primarily to alert individuals about threats to social bonds and motivate socially adaptive responses, presumably in service of the need for belonging. In addition to negative emotions, social isolation is associated with greater stress and psychopathology, lowered self-esteem, diminished self-regulation, and impaired immune system function. Over time, isolation may lead to loneliness and depression and is associated with an increased risk of suicide.

Further evidence that belongingness is a fundamental need comes from the powerful effects of relationship concerns on cognitive processing. Much of most individuals' thoughts and conversations revolve around their social relationships. There are also specific cognitive processes that focus on making sense of the social world, such as forming attributions and inferences about others' behavior. For example, people spontaneously use social relationships to classify information about individuals and tend to store information about relationship partners (e.g., a married couple) together in memory. Evidence also suggests that people process information about others in different ways depending on their relationship with the target. Many of the cognitive biases that normally favor the self are extended to close relationship partners. For instance, people tend to give more favorable explanations for the successes and failures of close relationship partners than they would for strangers.

Evolutionary Origins and Developmental Changes

There is strong evidence that the need for belonging is a cultural universal. Although specific patterns of relationship formation and maintenance differ somewhat across cultures (such as the existence of arranged marriages), humans universally seek out and maintain social relationships—friendship, family, and social groups in general exist in all known cultures. Humans everywhere seem to form relationships spontaneously, work to maintain their bonds, and express distress when their relationships end. Although there are clear cultural differences in specific patterns of relationships, there are no known societies where people fail to seek out the companionship of others.

The universal nature of the need for belonging has led several authors to theorize that the need for belonging is an innate adaptation with an evolutionary basis. For early humans, living in groups would have conferred numerous survival and reproductive benefits. Group living provided greater access to food and other resources and protection from predators and the environment. Some theorists have gone so far as to propose that small group living was the primary survival strategy of early humans. Because of the survival and reproductive benefits conferred by social relationships, human ancestors who were motivated to form, monitor, and maintain their social relationships would have been more likely to survive and reproduce. Recent research has also discovered specific neurological and neurochemical pathways that contribute to forming and maintaining social bonds, including the neurochemicals vasopressin and oxytocin.

Although the need for belonging is believed to operate from infancy, targets of belongingness and ways in which the need is met may change over time, as one's social focus shifts from parents to peers to romantic partners. Infants form emotional bonds and seek proximity with their caregivers. Adolescents tend to spend progressively less time with family and instead shift to a focus on developing friendships and eventually romantic partnerships. Early adulthood is similarly characterized by a focus on broadening one's social network. Older adults, presumably because they perceive their

time as limited, tend to focus more on emotionally close social bonds and less on acquaintances and new relationships, as shown by research on Socioemotional Selectivity Theory.

Individual Differences

Although the need for belonging appears to be universal and innate, there are individual differences in the intensity of the desire for belongingness that predict theoretically meaningful outcomes. For instance, one study found that individuals reporting a relatively strong need for belonging were more likely to cooperate with others in a large group setting. Individuals with a strong need to belong tend to seek a larger number of social relationships, worry more about acceptance, and react more negatively to exclusion. They are also generally more attentive to social cues, such as facial expressions and vocal tones. In addition to differences in chronic levels of the need to belong, the desire for belongingness is sensitive to context and can change over time and in different situations. For instance, situational threats such as being ignored by a friend can temporarily increase the strength of an individual's need for belonging, which may motivate him or her to attend more to social cues.

Although both men and women are believed to have a fundamental need for belonging, some findings suggest gender differences in the strength of this need. For instance, women tend to spend more time thinking about their relationships and show more ingratiating behaviors, such as smiling and attending to others in social situations. In laboratory experiments, women also tend to react more negatively to social rejection than men. Others, however, have proposed the alternative explanation that men and women are equally motivated by the need for belonging, yet they differ in how the need is met. In particular, evidence suggests that women tend to invest in a smaller number of close relationships, whereas men are more oriented toward social groups. For instance, whereas women are more likely than men to describe themselves in terms of their close relationships, men are more likely to use collective descriptors, such as group memberships.

Satisfying the Need for Belonging

Belonging does not merely refer to being liked or accepted, nor does it simply refer to any social contact. Mere affiliation (repeated contact with uncaring others) is not sufficient to satisfy the need for belonging and does not seem to enhance well-being. Rather, the need for belonging is satisfied most fully when an individual's social life is characterized by both frequent, pleasant social interactions and close, mutually caring relationships.

Some evidence suggests that the need for belonging, like the basic needs for food and water, operates according to a principle of satiation, in which fulfilling the need temporarily decreases its motivational power. People are most likely to seek out and develop additional relationships when they lack an adequate amount of belonging. In contrast, some studies have found that in some situations, social contact does not lead to satiation but rather to an increased desire for additional social contact. Further research is needed to identify the conditions under which each of these effects is likely to occur.

Some authors have argued that relationships are somewhat substitutable in terms of satisfying the need for belonging in that different relationships can satisfy the same underlying need. For instance, although moving from one location to another is often associated with temporary distress due to the loss of existing relationships, new friends usually fill the gaps left by former friends after some time. This does not mean that all types of relationships are essentially the same. In addition to a general need for belonging, individuals may also be motivated to form specific types of relationships, such as friendships and romantic partnerships, each with its own purpose. Although different types of relationships may all contribute to satisfying the need for belonging, they may also provide unique benefits unavailable in other types of relationships.

Responding to Threats to Belonging

When the need to belong is thwarted by social rejection or exclusion, individuals sometimes respond with anger and aggression, particularly toward the source of rejection. Social exclusion, however, also tends to motivate behavior that may ultimately enhance one's belongingness. Research

participants experiencing social exclusion in the laboratory have expressed greater interest in developing new friendships and in working with others. They exhibit greater generosity and conformity and expend more effort on group tasks. Exclusion also seems to make people more sensitive to social cues in the environment. For instance, recently rejected individuals are more likely to remember information regarding others' social relationships and group memberships. They are also more attentive to and accurate in decoding facial expressions and other subtle social cues, which may help them respond appropriately in social interactions. When others are not available, individuals often respond to threats to belonging by symbolically reaffirming their belongingness. For instance, research has shown that rejection makes one's social identities and group memberships come to mind more easily and leads people to think of their groups as more meaningful and cohesive. These reactions seem to buffer against the negative effects of rejection on self-esteem.

Not all behaviors enacted in the service of the need for belonging are prosocial, and people sometimes act in antisocial, aggressive ways in the service of belonging. For instance, one study found that boys in elementary school who wanted to be accepted by antisocial peers were more likely to bully other boys. In fact, some children admit that they go along with bullying because they do not want to feel left out of the group. Even though this behavior alienates victims of bullying, it may increase acceptance among antisocial peers. Similarly, some social groups, such as gangs, may pressure group members to commit criminal acts to avoid rejection from the group.

Given the fundamental importance of belonging, one might expect humans to have evolved psychological mechanisms to monitor and respond to changes in their social inclusion. Sociometer Theory argues that this is precisely the function served by self-esteem, which represents the output of a sociometer system that automatically monitors the environment for cues relevant to social inclusion or rejection and provides feedback regarding one's social acceptability. Research has confirmed that self-esteem is particularly reactive to experiences of social inclusion and rejection. Cues that imply the possibility of rejection or exclusion lower self-esteem, signaling the risk of

rejection and motivating behavior likely to restore social inclusion.

to terms with the loss of a relationship through death has much to do with the nature of the foregoing bond between the deceased and surviving person. Furthermore, just as current relationships with others (e.g., friends, parents, colleagues, siblings, neighbors, partners) influence virtually all aspects of everyday existence, so can the deaths of significant persons have profound impact on many domains of one’s life. Thus, it becomes important to determine precisely how and in what respect death of a loved one affects people and to identify subgroups for whom the impact is extreme. These issues are addressed in the first part of this entry. In the second part, theoretical approaches to understanding the identified manifestations of bereavement are outlined. Because bereavement has fundamentally to do with human relationships—not the forming or maintaining, but with the ending of a relationship—it stands to reason that a relationship theory could have much to offer in terms of scientific understanding and generation of theory-guided empirical research. One such theory, Attachment Theory, focuses on reactions to separation from a significant person and can be applied to the situation of separation when an attachment figure dies. Thus, particular attention is given to this theoretical approach. Finally, the impact of other human relationships in assisting the bereaved, both informally (through social support) and professionally (counseling and therapy), is summarized.

First, three basic terms need to be defined in the ways they are used in the contemporary scientific literature. *Bereavement* is the objective situation of a person who has recently experienced the loss of someone significant through that person’s death. *Grief* refers to the primarily emotional (affective) reaction to bereavement. It incorporates diverse psychological (cognitive, social-behavioral) and physical (physiological-somatic) manifestations. Grief is generally distinguished from *mourning*, which involves the public display, social expressions, or acts expressive of grief that are shaped by (religious) beliefs and practices of a given society or cultural group (e.g., mourning rituals). Some researchers and practitioners (e.g., those adhering to the psychoanalytic tradition) use the terms grief and mourning interchangeably.

BEREAVEMENT

It is frequently claimed that grief is the price one has to pay for love. Indeed, the way people come

Health Consequences of Bereavement

Mortality

The popular expression that she or he died of a broken heart has been subject to considerable empirical examination. Researchers have conducted well-controlled longitudinal investigations comparing bereaved and nonbereaved counterparts to establish whether bereavement is associated with higher rates of mortality. Most have focused on spousal loss. Excess risk of mortality among bereaved samples has been reported quite consistently for the early months of bereavement, with some investigators reporting persisting elevated risk beyond 6 months. Subgroup differences have been identified. Widowers appear to be relatively more vulnerable than widows. Death of a child, a highly impactful type of loss, has been shown to have a greater mortality effect on mothers than on fathers. Mortality excesses among the bereaved are due to various causes, with suicide being a significant risk. In one large-scale study conducted in Finland, mortality in a group of bereaved persons was found to be very high for accidental and violent causes, moderate for chronic ischemic heart disease and lung cancer, and lower for other causes.

There are good reasons to attribute the mortality excesses for the bereaved at least in large part to a “broken heart” effect if researchers understand this term to refer to psychological distress due to the loss, such as loneliness, and to secondary consequences of the loss, such as changes in social ties, eating habits, and economic support. Nevertheless, it must be remembered that in terms of absolute numbers, few bereaved people die (e.g., a study in England showed that within 6 months of bereavement, 5 percent of widowers vs. 3 percent of married men ages 54 plus would be expected to die).

Physical Health Consequences

Not surprisingly, given the mortality patterns just described, bereaved people are more likely to suffer physical health problems; again, this expectancy applies particularly to the recently bereaved. Rates of disability, use of medication, and hospitalization are elevated compared to nonbereaved controls. Widowed persons (and possibly other

bereaved subgroups on which there is less research) in general consult medical practitioners more frequently than their still-married counterparts. There are indications that this tendency is frequently due to symptoms of anxiety and tension. And yet, findings also suggest that many bereaved persons suffering from intense grief fail to consult their doctors when they need to, neglecting their own health. Clearly, patterns of physical health are intricately related to psychological symptoms and health.

Psychological Health Consequences

Bereaved people are susceptible to various psychological reactions-symptoms, causing bereavement researchers to regard grief as a complex emotional syndrome. Psychological effects also range from mild and comparatively short-lived, to severe and long-lasting over the months or even years following a loss. Psychological reactions are diverse not only between individuals but also across cultures and ethnic groups, with some differences attributable to religious beliefs. Nevertheless, there are reasons to believe that fundamental manifestations of grief are universal.

Bereavement is a harrowing experience that is frequently accompanied by loneliness, insomnia, distress, somatic symptoms, anxiety, and social withdrawal. For most people, the experience is tolerable and abates over time. For a minority, suffering is intense and prolonged. Depression or anxiety can, for example, reach levels that become clinically important (e.g., researchers have reported that 25–45 percent of recently bereaved samples suffer from mild levels of depressive symptoms and 10–20 percent from clinical levels). There is also risk of post-traumatic stress disorder, particularly when the nature of death was horrific. Comorbidity can occur; for example, a combination of such disorders as post-traumatic stress and a major depressive disorder may greatly complicate the grieving process. In line with such findings, bereaved persons have higher rates of psychiatric morbidity and psychiatric admission.

In some cases, the grieving process itself may become disturbed, leading to what has been termed *complicated* (or *prolonged*) *grief*. Complicated grief refers to a deviation from the (cultural) norm (i.e., that could be expected, according to the

nature of the particular bereavement event) in (1) the time course or intensity of specific or general symptoms of grief and/or (2) level of impairment in social, occupational, or other important areas of functioning. Subtypes of complicated grief have been described in terms of *absent*, *delayed* or *inhibited* (characterized by nonappearance of symptoms typical of grief), or *chronic* (long-lasting presence of symptoms of intense grief, absence of progress in coming to terms with loss) grief. There are discrepancies between studies in estimates of the occurrence of complicated forms of grief. For example, in one report among bereaved adults, 9 percent were found to experience chronic grief, while in another investigation it was reported that 20 percent suffered from complicated grief.

Risk Factors

Why do some bereaved people suffer from extreme or lasting effects while others do not? One step toward finding an answer lies in the identification of *risk factors*. The term risk factor denotes the situational and intra- and interpersonal characteristics associated with increased vulnerability to the range of bereavement outcomes outlined above. It seems useful in the case of bereavement to extend the concept to include protective factors that promote resilience and lower risk and coping processes that can impede or facilitate adaptation.

A complex combination of personal and situational factors contributes to bereavement outcome. For example, expected death is typically assumed to be easier to deal with than unexpected loss, but results are not always clear-cut. In one study, an interaction was found between personality and circumstances of death: Those who suffered a sudden loss but believed that in general they were in control of their own fate adapted better than those not holding such beliefs (and comparably with expected-loss survivors). Furthermore, discrepancies in findings make it difficult to establish patterns. For example, earlier research on the impact of good versus poor quality of a marital relationship associated ambivalence or dependency with poor consequent bereavement outcome, while good relationships were associated with better outcomes. More recent research has yielded less clear patterns. Further investigation (e.g., to distinguish overdependency from typical dependency, lack of

harmony from autonomy) is necessary to clarify inconsistencies. Nevertheless, research on attachment strongly supports the position that security in terms of attachment style is crucial to outcome.

With respect to intrapersonal resources and protective factors, there is evidence that personality characteristics are related to adjustment. For example, neuroticism (a dimension of personality relating to emotional instability, anxiety-proneness, and negative affectivity) is associated with poor bereavement outcome. A personal history of mental or physical health problems is associated with increased risk of ill-health effects during bereavement. Of interpersonal factors, although it has generally been assumed that social support assists the bereaved, evidence of a “buffering” (bereavement-specific protective) effect is weak.

Finally, the way a person goes about coping with bereavement makes a difference to adjustment. Ruminative coping (which involves repeatedly focusing on one’s symptoms of distress, such as asking oneself why one feels so bad) is associated with poor outcomes, whereas positive (re)-appraisal (a process whereby a person tries to also perceive some positive aspects in what is happening) is associated with good outcomes. Other factors have not always been well supported empirically: Analyses of the impact of confronting-working through grief or of disclosure and sharing of grief have failed to confirm that these factors are related to different (i.e., better vs. worse) outcomes, as had often been assumed by bereavement researchers. Similarly, the negative impact of denial has been called into question. By contrast, there are good reasons to claim that regulation of emotions (confrontation-avoidance, positive-negative appraisals) in grieving is likely to be beneficial.

Theories of Grief

Some theories are designed to explain manifestations and processes of grief in general, while others are specific to coping with bereavement. Both types are illustrated next.

Psychoanalytic Theory

Theoretical explanation of the phenomena and manifestations of bereavement has been influenced

by psychoanalytic theory, particularly Sigmund Freud's (1917) formulation in "Mourning and Melancholia." According to this perspective, when a loved one dies, the bereaved person is faced with the task of struggling to sever ties with the deceased person and to detach the energy invested in him or her. The psychological function of grief is to free the individual of ties to the deceased, achieving a gradual detachment by means of a process of *grief work* (confronting the reality of loss, going over events, working toward detachment). This notion that one has to work through grief has been central in subsequent formulations and in principles of counseling and therapy (notably, John Bowlby's identification of phases of grief and William Worden's Task Model, which assumes that the bereaved person has to perform four tasks to adjust to bereavement: accepting the reality of loss, experiencing the pain of grief, adjusting to an environment without the deceased, and "relocating" the deceased emotionally). The main cause of complicated grief, according to Freud, is the existence of ambivalence in the relationship with the deceased, preventing the normal transference of libido from that person to a new object.

Cognitive Stress Theory

The basic assumption of cognitive stress theories, notably that of Richard Lazarus and Susan Folkman, is that stressful life events play an important role in the etiology of various somatic and psychiatric disorders. A stressful life event may precipitate the onset of a physical or mental disorder, particularly if the person is predisposed to such disorder. The experienced distress depends on the extent to which the perceived demands of the situation tax or exceed the person's coping resources, given that failure to cope leads to negative outcomes. Coping may be directed toward managing and altering the problem that is causing the distress (*problem-focused coping*) or at managing the emotional response (*emotion-focused coping*). This theory provides a theoretical basis for the *buffering hypothesis*, which suggests that social support (a coping resource) protects the individual against the negative impact of stress on health. Research has identified neurophysiological mechanisms linking stress to the immune, gastrointestinal, and cardiovascular systems.

Attachment Theory

Bowlby's Attachment Theory places emphasis on the biological function of grieving, namely, to regain proximity to the attachment figure, separation from whom has caused anxiety. In the case of death, reunion cannot be achieved, and this searching response is dysfunctional; protest and despair result. Actively working through the loss is considered necessary, to rearrange representations of the lost person and the self (which become internalized attachment working models of self and others) and enables detachment-reorganization and adjustment to the physical absence of the deceased. Working through takes place through a sequence of overlapping, flexibly occurring phases (shock, yearning-protest, despair, and recovery).

According to Bowlby, individuals with negative models of self and others, and who suffer from chronic attachment insecurities, are likely to have special difficulties grieving. Anxiously attached individuals have difficulty inhibiting painful thoughts and feelings relating to the deceased (relating to chronic grief). By contrast, avoidant ones will be unwilling or unable to experience such things (relating to absence of grief, denial, and inhibition). In both cases, difficulties coming to terms with the loss and moving on (to form new attachments) ensue, while secure attachment facilitates adjustment during bereavement.

The Dual Process Model (DPM)

The DPM was developed by Margaret Stroebe and Henk Schut to clarify differences between adaptive and maladaptive coping with bereavement and to specify cognitive processes (beyond grief work) that would be associated with these outcomes. It distinguishes between two types of stressor, namely *loss-oriented* (focusing on the deceased and death events, including grief work) and *restoration-oriented* (dealing with secondary stressors—e.g., finances, changes in other relationships—resulting from the death). Both need to be dealt with during adjustment, leading to a dynamic process called *oscillation*: Adaptive grieving not only involves grief work but also confrontation-avoidance of positive-negative emotions and cognitions associated with loss itself and its consequences for ongoing life. For example, in addition to confronting the reality of loss through reminiscing about the deceased, visiting

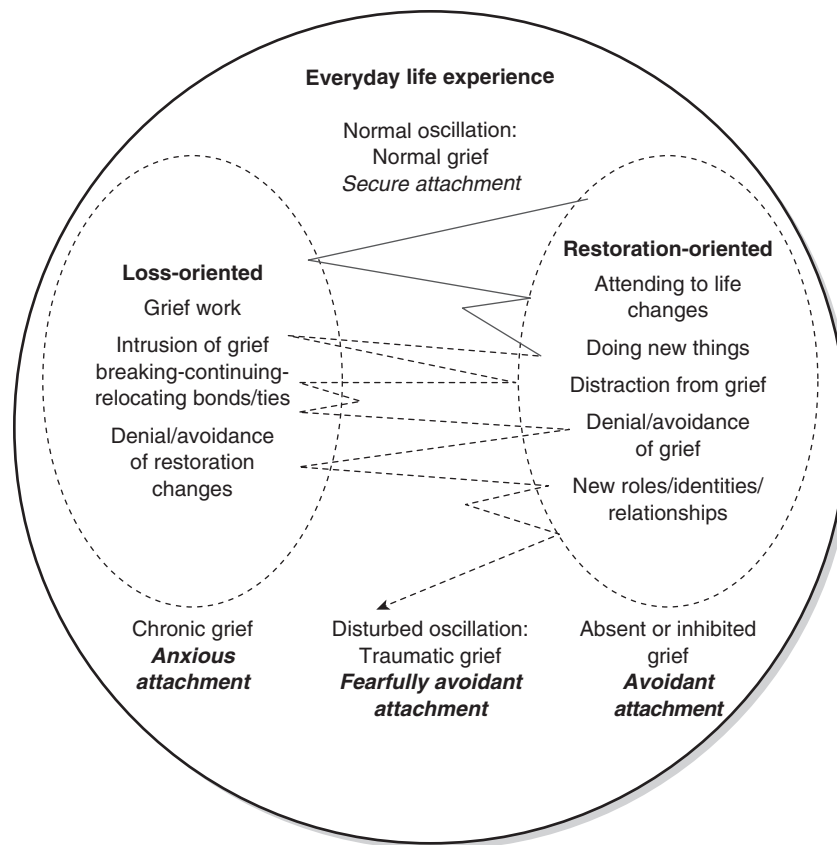

Figure 1 Complicated Grief in the Dual Process Model (DPM): A Theoretical Model of the Process of Grieving

Source: Stroebe, M., & Schut, H. (1999). The Dual Process Model of Coping with Bereavement: Rationale and description. *Death Studies*, 23, 197–224. Reproduced with permission.

the grave, and so on, a bereaved spouse may have to deal with matters that the deceased had taken care of (e.g., the family finances). Lack of experience and skills in the latter domain could cause additional anxiety, distress, and feelings of incompetence.

The DPM is compatible with both cognitive-stress and Attachment theories. Put simply, securely attached individuals would be expected to oscillate more easily between loss-orientation and restoration-orientation and would not suffer complications in their grieving. Insecure persons high on the anxiety dimension would tend to be more exclusively loss-oriented and display more chronic forms of grieving. Avoidant individuals would tend to be the most restoration-oriented, delaying or inhibiting their grief, while fearfully anxious persons would have a more disturbed, less coherent manner of oscillating between these orientations. These patterns are depicted in Figure 1.

Role of Others in Alleviating Suffering

It is commonly believed that others play an important role in helping the bereaved come to terms with their loss. However, scientific research suggests the need for caution in drawing such general conclusions and for further investigation to determine what precisely is helpful and for whom.

Informal Social Support

Nearly everyone who has been through bereavement talks about how good it is to have friends and family around. Rituals and procedures that surround the bereaved person with friends and family are characteristic of most (though not all) cultures. Nevertheless, the assumption that social support from others (family, friends, neighbors, etc.) buffers individuals against the negative health outcomes has not been well supported empirically.

Research so far has shown that inadequate social support is a general risk factor; it affects the health and well-being of nonbereaved persons as much as the bereaved. In the case of bereavement, it appears that others cannot easily make up for, or take the place of, the deceased. Support is perceived as helpful, and is helpful, but not in the sense that bereaved persons who perceive themselves to be highly supported by others are relatively more protected or adjust relatively more quickly to the loss than those without such perceptions. Others do not seem to be able to compensate for—or reduce the level of grief due to—the loss of a special attachment figure.

Formal Intervention

According to Worden, professional intervention for bereaved persons encompasses *counseling* (facilitation of the process, tasks of normal, uncomplicated grieving to alleviate suffering) and *therapy* (specialized techniques to guide complicated grief reactions toward a normal coping process). To evaluate the efficacy of interventions, Schut and Stroebe distinguished three types of program: *Primary preventive interventions* are those where professional help is available to all bereaved persons, irrespective of whether intervention is indicated. *Secondary preventive interventions* are designed for bereaved individuals who, through screening or assessment, can be regarded as vulnerable to the risks of bereavement. *Tertiary preventive interventions* are those providing therapy for complicated grief, grief-related depression, or post-traumatic stress disorders.

There is no evidence that a referral to counseling is necessary or helpful for all bereaved people: Suffering from bereavement is not grounds enough for routine referral, although many bereaved persons choose to participate in support groups (i.e., encompassing both primary and secondary intervention). Primary intervention can be helpful if the bereaved person takes the initiative to receive it (indicating a personal desire or need). Secondary preventive intervention obtains somewhat better results; but to improve these results further, better identification of risk factors is necessary. Tertiary preventive interventions, incorporating a wide variety of treatment modalities, are generally quite effective.

Conclusions

Loss of a loved one causes deep suffering and is associated with costs to mental and physical health, justifying scientific study and theoretical understanding. Nevertheless, it is important to remember that grief is a natural—albeit for many persons harrowing—process after bereavement. Most people get by without the aid of professional help. For the comparatively small number of persons for whom complications develop, specific intervention programs have been designed that help reduce extreme consequences and restore grieving to a normal course, which in time (which varies between persons and cultures and may not be limited to a calendar year, as often expected) evolves toward adjustment to life without the loved person.

BETRAYAL

Although relationships with family, friends, and romantic partners can bring people some of their greatest joys, they are also the source of some of their most painful hurts. When individuals enter into relationships with friends, family members, coworkers, team members, authority figures, romantic partners, and others, they bring to those relationships beliefs or expectations about what they can expect from those relationships. For example, people expect friends to be loyal, romantic partners to be faithful, family members to be truthful, and authority figures to be fair. In spite of these expectations, however, people in relationships often engage in relational or interpersonal transgressions whereby they violate the rules or expectations that exist in those relationships. Such breaches of relationship expectations are referred to as betrayals. No one is immune to the experience of betrayal. Everyone has experienced minor and major forms of betrayal, and almost everyone has, at some point, betrayed others. The pain behind a betrayal arises from the fact that not only has someone violated relational expectations but also a trusted individual has lied, cheated, or broken implicit and explicit agreements. This entry provides an overview of what the field knows about betrayal, with particular attention paid to variations in responses to betrayal and its consequences.

Conceptualizing Betrayal

Although many people equate betrayal with instances of marital infidelity, betrayal is a much broader term that includes lying, criticism, broken promises, intentional embarrassment, humiliation, belittlement, and gossip. Any aversive event that involves violations of expectations, trust, and commitment can be considered a betrayal. As this list of exemplars of betrayal implies, betrayals lie along a continuum of severity from minor infractions (e.g., telling a little white lie) to more severe breaches of trust (e.g., cheating on one's spouse). Even minor betrayals, such as a white lie or a forgotten birthday, when repeated over time can produce significant damage in a relationship.

Betrayals can be accidental or intentional. With accidental betrayals, the perpetrator unintentionally violates the rules of a relationship without meaning to do so; for example, he or she may disclose a secret, not realizing that the target of the secret did not mean the secret to be shared. Intentional betrayals include a myriad of different types of behaviors. Some intentional betrayals are premeditated and involve actions that are designed explicitly to betray (e.g., for revenge). Another class of intentional betrayals involves actions that are perpetrated for other reasons (e.g., people have affairs because they fall in love with someone other than their spouse). In this case, the betrayal is a side effect of, rather than the objective of, the behavior. Yet another class of intentional betrayal, opportunistic betrayals, occurs without planning and thus, does not always involve a reward-cost analysis.

Regardless of the specific type of betrayal, all forms of betrayal result in loss: loss of trust; loss of a relationship or friendship; loss of a sense of security and predictability, loss of time, energy, and effort devoted to that relationship or friendship; loss of integrity; and loss of self-esteem. Ultimately, all forms of betrayal signify rejection and relational devaluation. People who are betrayed feel that the betrayer does not value his or her relationship with them as much as he or she once did. Victims feel, often correctly, that the betrayer has put his or her own needs or desires above their own. Given the potency of the need to belong, the strength of aversive reactions to the rejection and devaluation inherent in betrayal is not surprising.

Betrayals occur in all types of relationships, including those involving romantic partners, friends, family, and colleagues. Whether a particular behavior constitutes a betrayal depends on the rules and expectations understood to exist in a particular relationship. In most marriages, for example, the two individuals agree that they will be intimate with only each other. Should one partner have an extramarital affair, the other individual will perceive that the betrayer has violated the implicit rules and expectations of monogamy. On the other hand, marital partners who have agreed to an open marriage will be unlikely to feel betrayed because they do not define sexual infidelity as betrayal.

People betray others for a wide range of reasons that vary somewhat with the type of betrayal being

discussed. On the positive side, they may betray a friend's secret (e.g., revealing that a friend has an eating disorder) to get needed help for the friend. On the negative side, people may betray others to hurt them, to seek a reward or an experience for themselves without regard for its impact on others, or to seek revenge. For example, a spouse may lie about an affair so that he or she can continue to maintain both relationships. A friend may break a confidence in order to hurt the target of the secret. Not surprisingly, positive motives for betrayal are generally other-focused, whereas negative motives for betrayal are self-focused. However, both positive and negative betrayals may produce negative feelings and reactions in the victim. The confidence revealed out of concern for a friend will likely produce similar reactions, at least initially, as the confidence revealed in an effort to hurt a friend or to damage that friend's reputation.

Responses to and Consequences of Betrayal

People who have been betrayed report feeling a number of emotions including anger, anxiety, depression, jealousy, hopelessness, sadness, bitterness, and hurt feelings. They report feeling "let down," and they begin to search for meaning behind the betrayer's behavior. Many people who have been betrayed experience lowered self-esteem and shattered identities, particularly if their identity was closely tied to the person who betrayed them. The range of emotions experienced and the depth of these emotions following a betrayal depend on characteristics of the victim and the perpetrator as well as the relationship between the two. They also depend on the seriousness of the norm violation. A white lie is much easier for most people to overcome than marital infidelity. The emotional reactions also vary with the attributions that the victim makes for the betrayer's actions. If the victim views the betrayal as accidental or as a "slip-up" that is unlikely to happen again, then his or her affective response will be attenuated relative to a victim who views the betrayal as an intentional, premeditated, selfish act.

Victims of betrayals, particularly major betrayals, often have difficulty letting go of the negative emotions that follow the betrayal and not surprisingly, often find it difficult to trust not only the betrayer again but also others. This lack of trust

often leads them to make negative attributions for the betrayer's future behavior, even when that behavior is innocent. Victims experience relational devaluation, feeling as if their friend, family member, or relationship partner no longer values them as much as they once did or as much as they would like them to.

The type of emotion experienced following a betrayal determines the response offered. For example, people who feel dejected following a betrayal may withdraw from the betrayer, whereas those who feel hatred may lash out in anger. Surprisingly, although anger is often a prominent emotion following a betrayal, few people retaliate in response to being betrayed. Acts of revenge, although frequently fantasized about, are rarely enacted. More common responses range from forgiving the betrayer to distancing oneself from him or her. The response of the betrayed person is influenced, in part, by the willingness of the betrayer to apologize and atone for his or her actions. However, forgiveness does not always directly follow an apology. The longer the period of time between the offense and the apology, the less likely a victim is to forgive. Forgiveness also varies with the sincerity of the apology and with the number of betrayal episodes for which apologies are sought. In other words, betrayals can exert a cumulative damaging effect such that a victim may be willing to forgive one indiscretion but not more. Relatedly, one reason people find serious betrayals such as infidelity difficult to forgive is because they involve multiple forms of betrayal. On the one hand, the betrayer has broken the rules of sexual and emotional exclusivity inherent in the relationship. Second, the betrayer has likely gone to great lengths to keep the betrayal a secret, so multiple lies have been told. Third, the revelation of the secret is often news to the partner but often not to others, resulting in embarrassment and humiliation.

Perpetrators, too, may experience a range of negative emotions, including sadness, guilt, and shame. Because perpetrators tend to view their behavior less negatively than victims do and see it as having fewer long-term consequences, they may experience anger as the continued mistrust and negativity of the victim. Shame and guilt play interesting roles with betrayal. Feelings of guilt may motivate a betrayer to confess his or her betrayal as

a means of alleviating the guilt. Alternatively, guilt experienced as a result of empathy with the hurt experienced by the betrayed may motivate efforts to seek forgiveness and reconciliation. Shame, similarly, can produce divergent behaviors. Betrayers who feel shame may either withdraw from the betrayed person or may lash out in anger at that person, perhaps blaming him or her for causing the betrayal. For example, a man who feels ashamed for having cheated on his wife may blame her for the affair, saying that he would not have strayed if she had been a better wife.

Whether relationships end as a result of betrayal depends on the type of betrayal, the commitment to and investment in the relationship of the individuals involved, the repetitiveness of the offense, the contrition of the betrayer, and the willingness to forgive, to name a few factors. Individuals in long-term, committed relationships in which they have a significant investment (e.g., time, money, children) are less likely to end their relationships, particularly following a single betrayal, than people in less committed relationships. Furthermore, in some instances, friends and relationship partners report improved relations following a betrayal. The act of betrayal may bring to the forefront issues in the relationship that had been simmering beneath the surface. Once these issues are brought out into the open and dealt with, some relationships improve. Not surprisingly, perpetrators are more likely than victims to report improvements in relationships.

BIOLOGICAL SYSTEMS FOR COURTSHIP, MATING, REPRODUCTION, AND PARENTING

Recently, social psychologists, neuroscientists, and physiologists have begun to explore the biological systems that are involved in love and sexual desire, courtship, mating, reproduction, and parenting. In *Why We Love*, Helen Fisher argues that people possess a trio of primary brain systems designed to deal with these aspects of close intimate relationships. These are attraction (passionate love), lust (sexual desire), and attachment (companionate love). Presumably, these diverse systems evolved during humankind's long evolutionary history; each plays a critical role in courtship, mating, reproduction, and parenting. In theory, attraction evolved to persuade our ancestors to focus attention on a single favored courtship partner. Sexual desire evolved to motivate young people to seek a range of appropriate mates and sexual partners. Attachment evolved to ensure that parents would remain together for the first few crucial years of a child's life and for parents and children to form secure attachments. This

entry reviews what scholars have learned about these complex brain systems, which have been found to interact in a myriad of ways.

Love, Sexual Desire, Courtship, and Mating

According to Fisher, attraction (passionate love) is characterized by a yearning to win a preferred mating partner. She observes that the attraction brain system is primarily associated with increased dopamine in the reward centers. There is also increased activity of central norepinephrine and decreased activity of central serotonin. Other brain systems also contribute to produce the range of cognitions, emotions, motivations, and behaviors central to romantic love.

Sexual desire (lust), on the other hand, is typified by a general craving for sexual gratification and may be directed toward many potential partners. In men and women, the androgens, particularly testosterone, are central to sparking sexual desire.

Many neuroscientists contend that passionate love and sexual desire are in fact tightly linked. Andreas Bartels and Semir Zeki, for example, (using functional magnetic imaging [fMRI] techniques) attempted to identify the brain regions associated with passionate love and sexual desire. They put up posters around London, advertising for men and women who were “truly, deeply, and madly in love.” Seventy young men and women from 11 countries and several ethnic groups responded. Those who scored highest on the *Passionate Love Scale (PLS)* were selected for study. These people were placed in an fMRI scanner. This high-tech scanner constructs an image of the brain in which changes in blood flow (induced by brain activity) are represented as color-coded pixels. Bartels and Zeki gave each person a photograph of their beloved to gaze at, alternating the beloved’s picture with pictures of other casual friends. They then digitally compared the scans taken while the participants viewed their beloved’s picture to those taken while they viewed a friend’s picture, creating images that represented the brain regions that became more (or less) active when people viewed their beloved’s picture. These images, the researchers argued, revealed the brain regions involved when a person experiences passionate love and/or sexual desire.

Bartels and Zeki discovered that passion sparked increased activity in the brain areas associated with euphoria and reward and decreased activity in the areas associated with sadness, anxiety, and fear. Activity seemed to be restricted to foci in the medial insula and the anterior cingulate cortex and, subcortically, in the caudate nucleus, and the putamen, all bilaterally. Most of the regions that were activated during the experience of romantic love are those that are active when people are under the influence of euphoria-inducing drugs such as opiates or cocaine. Apparently, both passionate love and those drugs activate a “blissed-out” circuit in the brain. The anterior cingulate cortex has also been shown to be active when people view sexually arousing material. This makes sense since passionate love and sexual desire are generally assumed to be tightly linked constructs.

Among the regions where activity decreased during the experience of love were zones previously implicated in the areas of the brain controlling critical thought (i.e., the sort of mental activity involved in making social judgments and in mentalizing—that is, in the assessment of other people’s intentions and emotions) and in the experience of painful emotions such as sadness, anger, and fear. The authors argue that once we fall in love with someone, we feel less need to critically assess their character and personality. (In that sense, love may indeed be “blind.”) Deactivations were also observed in the posterior cingulate gyrus and in the amygdala and were right-lateralized in the prefrontal, parietal, and middle temporal cortices. Once again, the authors found passionate love and sexual arousal to be tightly linked.

This is only one-half of the equation, of course. Love is often unrequited. What kind of brain activity occurs when passionate lovers are rejected?

Fisher and her colleagues studied 15 men and women who had just been jilted by their beloved. The authors followed much the same protocol as that utilized in happily-in-love participants: They asked participants to alternately view a photograph of their one-time beloved and a photograph of a familiar, emotionally neutral individual. The authors found that when contemplating their beloved, rejected lovers displayed greater activity in the right nucleus accumbens/ventral putamen/pallidum, lateral orbitofrontal cortex and anterior insular/operculum cortex than they did when contemplating

neutral images. In short, jilted lovers' brains "lit up" in the areas associated with anxiety, pain, and attempts at controlling anger as well as addiction, risk taking, and obsessive-compulsive behaviors. Jilted lovers appear to experience a storm of passion—passionate love, sexual desire, plus anguish, rejection, rage, emptiness, and despair.

Other neuroscientists who have studied the fMRI responses of lovers who are actively grieving over a recent romantic breakup secured slightly different results. Fisher speculates that such differences are probably due to the fact that while she and her colleagues study young people who are actively grieving the loss of love, her critics have focused on men and women who broke up some time ago and have presumably adapted to their losses. Instead of at the grief stage, they may have been at a subsequent stage in the grieving process—experiencing resignation and despair. The use of fMRI techniques are, of course, very new and definitive answers as to the precise nature of love and sexual desire will have to await further research.

Attachment, Reproduction, and Parenting

According to Fisher, attachment (which she also labels *companionate love*) is comprised of feelings of calm, social comfort, emotional union, and the security felt in the presence of a long-term mate. It sparks affiliative behaviors, the maintenance of close proximity, separation anxiety when closeness disappears, and a willingness to participate in shared parental chores. Animal studies suggest that this brain system is primarily associated with oxytocin and vasopressin in the nucleus accumbens and ventral pallidum.

Currently, researchers provide some support for Fisher's contentions. Sue Carter and her colleagues, for example, set out to investigate the neurobiology of monogamy and pair-bonding. In mammals, monogamy is characterized by close pair-bonds (often for life), both parents' participation in care of offspring, reproduction regulated by social stimuli, incest avoidance, and selective aggression against outside rivals. Nonmonogamous mammals would, of course, be lacking in these characteristics. To study the antecedents of pair-bonding-nonpairbonding, scholars selected two prototypic rodents: prairie voles and meadow and montane

voles. Prairie voles inhabit the grasslands of midwestern North America. These voles are highly social and monogamous. A breeding pair lives in a communal family, with male and female breeders and their offspring. Pair-bonded males are highly aggressive following mating and often patrol the perimeter of the nest. The pair-bonds may last until "death do them part." Their counterparts, the meadow voles and montane voles, are less social, do not form pair-bonds, are nonmonogamous, and the fathers do not participate in the rearing of infants.

Over the decades, ethnologists and neurobiologists have amassed a great deal of information about the nature of pair-bonding in the various types of voles. During the course of these observations and experiments, scientists have identified a number of substances that facilitate pair-bonding, monogamy, and parental behavior. First and foremost, a number of peptides, including oxytocin and vasopressin, which are released during mating, have been found to facilitate pair-bonding, social affiliation, and maternal behavior. In fact, neurobiologists generally refer to oxytocin as the "affiliative neuropeptide." In male prairie voles, stress and vasopressin stimulate territoriality and defensive behaviors. Another class of brain neurotransmitters, called *opioids*, also appears to play a crucial role in facilitating pair-bonding and affiliative behavior. (Opioids are naturally occurring compounds that act in the brain much like opium, morphine, or heroin.) It is speculated that such opioids facilitate mother-child bonding and maternal care.

Interestingly, both Sue Carter and Shelley Taylor point out that social and environmental factors may play a critical role in shaping prairie vole monogamy. The hypothalamic-pituitary-adrenocortical axis (HPA) is sensitive to the social and physical environment and is exceptionally active in prairie voles. Thus, they speculate, HPA hormones (including various peptides and steroids) may be a mechanism through which social factors can influence pair-bonding and monogamy in prairie voles.

The Interaction Between Various Systems

Nature is parsimonious. Some neuroscientists and neurobiologists point out that in mankind's

affectional system, the triune structures that Fisher discusses, are in fact tightly linked. Bartels and Zeki, for example, point out that passionate love and maternal love are both highly rewarding experiences—both are closely linked to the perpetuation of the species. When these scientists compared the fMRI brain activity of mothers viewing pictures of their own children versus a variety of more neutral pictures, they discovered that romantic love and maternal love had much in common. Both types of attachment sparked activity in the brain's reward system—the areas that are rich in oxytocin and vasopressin receptors. Both deactivated a common set of regions associated with social judgments, mentalizing, and negative emotions.

End of the Affair

Fisher closes her analysis of the brain systems sparking attraction, lust, and attachment by observing that passionate attachments are by their nature time-bound. She argues that in the course of evolution, ancestors came to be genetically programmed to meet, mate, and move on—a strategy designed to create optimal genetic variety in the young. When she examined the data from 58 human societies selected from the *Demographic Yearbook of the United Nations*, she discovered that in the majority of societies, couples tend to separate and divorce around the fourth year of marriage. Fisher notes that (a) many socially monogamous species form pair-bonds that last only long enough to rear the young through infancy and that (b) in hunting-gathering societies, it generally takes 4 years to rear a child. (Children in such societies join in multiage play groups soon after being weaned, becoming the responsibility of relatives and older siblings.) Thus, she hypothesizes that it may be natural for young couples to meet, court, marry, reproduce, and remain together only long enough to raise a child. After that period, the chemistry of attraction (the stew of increased dopamine, decreased serotonin, and increased norepinephrine) swings into action, and men and women begin to feel the ancient tugs of attraction, sexual desire, and finally attachment yet again.

BIRTH CONTROL, RELATIONAL ASPECTS

Effectively using birth control to prevent unintended pregnancy involves a complex array of individual beliefs, attitudes, motives, and competencies. As relationships progress, however, birth control is more about decision making and negotiation at the couple rather than at the individual level, so relationship characteristics become increasingly important. Moreover, the motivation for using birth control can be complex; many long-term couples desire a pregnancy eventually, so an unintended pregnancy may not be entirely unwanted. Understanding couples' birth control behavior, therefore, requires understanding the couple's relationship, their motivation to use contraception, and the ways they discuss and negotiate the possibility of pregnancy.

Birth Control by Relationship Characteristics

The method of birth control used by a couple varies as a function of relationship length and type.

Because couples protect against both pregnancy and sexually transmitted infections (STIs), condoms are the preferred contraceptive method with casual sexual partners and in the early stages of relationships. Among heterosexual couples, a small proportion (about 10 percent) use both condoms and other hormonal methods (e.g., the Pill or contraceptive injections) at the beginning of a relationship. Many, however, initially rely solely on condoms to protect against both unintended pregnancy and STIs until the relationship becomes serious at which point they switch to other methods, often the Pill.

The decision to make this switch is typically taken as a function of sexual frequency and on the strength of one's feelings of commitment rather than on any actual evaluation of STI risk. Commitment refers to one's attachment to the relationship and to the decision to maintain the relationship into the future. High levels of commitment predict perceiving that one's partner is safe and thus deciding to adopt more effective, hormonal, birth control methods. However, commitment does not necessarily predict more consistent use of these methods.

Motivation to Use Birth Control

Commitment to the relationship can reduce one's motivation to avoid pregnancy. The motivation to avoid pregnancy influences how consistently and regularly a couple uses contraceptives, as well as the efficacy of the methods used. In established couples, the motivation to avoid pregnancy varies over the stages of the relationship and characteristics of the relationship. Motivation to avoid pregnancy tends to be lower if a couple is living together, has fewer children at home, and has a long-standing relationship.

Couples in highly committed relationships may be less motivated to avoid pregnancy because they are less concerned about an unplanned pregnancy. They may feel more confident in their partner's support should an unintended pregnancy occur and in their ability to deal with the consequences. In some cases, pregnancy, or the willingness to risk pregnancy, is offered as evidence of commitment even though a pregnancy is not explicitly intended. Feelings of commitment may therefore have a

complicated relationship to birth control use and in some relationships, may be associated with decreased birth control use.

In established and married couples, individuals' own motives to avoid pregnancy are strongly influenced by their partner's motivation to avoid having children. The motivation of both members of the couple then predicts the regularity of the couple's contraceptive use. Perceived partner preferences regarding specific contraceptive methods also strongly influences the type of method preferred when couples consider changing contraceptive methods. Partner dissatisfaction and discomfort with a contraceptive method is often reported as a reason why individuals switch methods of contraception or use contraception inconsistently. Individuals are therefore influenced by their partners and their relationships not only in their motivation to avoid pregnancy but also in their motivation to use specific methods of contraception.

Negotiating Birth Control Use

Whereas commitment can reduce contraceptive use, intimacy supports more reliable contraceptive behavior. Intimacy refers to feeling a close connection with one's partner, to mutual self-disclosure, and to open communication. Couples reporting more intimacy are consistently found to report more regular and effective birth control use. The link between intimacy and contraceptive behavior appears to be due to communication. Couples in more intimate relationships are more likely to communicate with their partners about everything, including birth control and their motivation to avoid pregnancy. This relationship goes both ways; successfully discussing and negotiating contraceptive behavior can also increase a couple's sense of intimacy.

Poor communication can lead to misperceptions of partner pregnancy motives and method preferences, which can lead to conflict and unreliable contraceptive behavior. Poor communication is particularly problematic for couples who decide to permanently terminate childbearing through either male or female sterilization. Although approximately 30 to 40 percent of married couples using contraception in North America choose sterilization, it has been reported that as many as

10 percent of individuals regret being sterilized. Regret is more likely if the decision was dominated or pressured by the nonsterilizing spouse or made without adequate spousal communication.

Power dynamics in relationships are also critical in birth control use. When one partner controls more emotional or physical resources in a relationship, his or her knowledge and motivation to use birth control determines the couple's behavior, including the choice of who gets sterilized. Several studies have found that women have more power in contraceptive decision making in dating couples perhaps because contraception is seen as a woman's issue. Among adult and married couples, however, contraceptive decision making may be more strongly related to general decision-making power. Power is particularly relevant with respect to condoms. In a relationship with unequal power, ensuring condom use against a partner's wishes can be difficult and at its most extreme, dangerous. Relationships marked by physical and/or verbal abuse are associated with higher levels of unprotected intercourse, STIs, and unintended pregnancies.

Summary

Although a couple's birth control behavior is a product of their individual motivations and preferences, these motivations and preferences are highly influenced by their interactions with and perceptions of their partner. Of particular importance is the couple's ability to communicate about their needs, preferences and goals. The association between relationship variables and birth control use emphasizes that sexual behavior exists in the context of interpersonal relationships and highlights the importance of considering both members of a couple when promoting effective contraceptive use.

BODY IMAGE, RELATIONSHIP IMPLICATIONS

First impressions are substantially based on readily apparent physical features, and in this process, physically attractive people are perceived to possess more socially desirable personality characteristics than physically unattractive individuals. Due to this physical attractiveness stereotype, matching attractiveness standards is an important personal goal for many people, and it significantly shapes self-perceptions. Body image, which is also referred to as body concept, is a person's perception of her or his physical self. A person's evaluation of her or his body image is referred to as body esteem. Body image is an essential component of both personal and social relationships, and it varies between the sexes and across cultures and situations.

Although social scientists once assumed that people perceive and evaluate their bodies as a unified whole, research conducted beginning in the 1980s revealed that body image is multidimensional. For many women in North American culture, the most important dimension of body image is weight concern, while for men upper body strength is a defining dimension of the physical self.

Physical attractiveness has historically been a more important quality for women than for men to possess. Given the high value placed on female physical attractiveness, women frequently express concerns about being rejected based on their appearance. Starting at a very young age, females are taught that their body as an object is a significant factor in how others judge their overall value. In contrast, males are taught to view their bodies

as dynamic instruments of action, and they are judged more positively if they engage in physical activities. For boys, their ability to adeptly move their bodies through physical space is an important contributor to their overall self-esteem. In adulthood, power and function are important aspects of male body image, and the male body-as-object is judged more positively if it is muscular.

In romantic relationships, although physical attractiveness is a more valued commodity for women than for men, this relationship is reversed in homosexual romantic relationships: Physical attractiveness is a more important quality for gay men than it is for lesbians. This finding suggests that men, regardless of their sexual orientation, place greater value on the physical appearance of a potential romantic partner than do either lesbians or heterosexual women. The greater scrutiny of the physical self received by men's romantic partners than women's romantic partners may well explain why heterosexual women and gay men respectively judge their own bodies more negatively than do lesbians and heterosexual men.

Among heterosexual adults, the gender difference in placing importance on physical attractiveness is most apparent when people are contemplating long-term romantic relationships rather than casual short-term sexual encounters. When considering partners for casual short-term sexual relationships, women, like men, place relatively high value on physical attractiveness. Although men place more importance on physical attractiveness than women when evaluating potential long-term romantic partners, there is some evidence that this gender difference may be diminishing due to women achieving more economic equality in their careers. In other words, as heterosexual women achieve more financial independence, they may look for more beauty in men similarly to the historical manner in which men have emphasized beauty in their romantic partners.

Through the process of social comparison, popular culture plays an important role in shaping the body image and body esteem of both children and adults. In North American culture, print and electronic media convey difficult-to-attain standards of feminine beauty, especially related to weight. This focus on the feminine body ideal has a lasting negative impact on female body image. Beginning in late childhood and early adolescence,

not only do girls experience more dissatisfaction with their bodies than boys, but also they experience a steady increase in this dissatisfaction over time. By adulthood, negative affect is a pervasive quality of female body esteem. Compared to men, women are more likely to habitually experience social physique anxiety, which is anxiety about others observing or evaluating their bodies.

There is evidence that African-American women feel less pressure to conform to the unrealistic feminine thinness standards of North American culture. This ethnic difference is a likely explanation for the more positive body esteem that African-American women have compared to White, Latino, and Asian-American women. Despite this healthier body image, African-American women are still more dissatisfied with their bodies than African-American men. The only American young adults who do not exhibit gender differences in body esteem are first-generation citizens whose families previously lived in countries with limited exposure to American culture. The lack of gender differences among these new immigrants is likely due to their relatively low internalization of cultural beauty norms related to thinness.

Although men generally have more positive body esteem than women, their negative body attitudes are often linked to muscular masculine body standards. Recent studies of American college students indicate that over 90 percent of men desire more muscularity. This desire for muscles is not a new phenomenon, nor is it unique to North American culture. However, heightened media and cultural attention to this masculine body ideal is playing a role in the increasing trend of male body dissatisfaction in a number of industrialized countries. In an attempt to reach this hypermuscular male standard, an increasing number of teenage boys and young men are taking anabolic steroids and untested dietary supplements, which can cause a variety of health problems.

Finally, besides these broad-based cultural influences, body image and body esteem is often temporarily altered by situational cues. In the act of comparing themselves to others, individuals of average physical appearance feel prettier or more handsome after seeing same-sex persons who fall well below conventional beauty standards. Similarly, these same individuals feel less attractive

after comparing themselves to same-sex persons who more closely match the “perfect 10” physical standards. People who are most affected by such comparisons are individuals who place high importance on their own physical appearance.

BOGUS STRANGER PARADIGM

The bogus stranger paradigm was developed by the social psychologist Donn Byrne to study the role of attitude similarity and dissimilarity in interpersonal attraction. The method was originally devised to allow experimenters to vary the degree of agreement and disagreement between a hypothetical (bogus) other and a participant in order to examine their effects on liking and disliking. Since then, it has been adapted to examine a variety of other factors in attraction as well.

The bogus stranger paradigm used an experimental approach. The purpose was to examine the causal effect of similarity-dissimilarity on attraction. In the basic study, degree of similarity was the manipulated independent variable and liking

expressed for the bogus other was the dependent variable. The original procedure involved administration of a survey of opinions to a large psychology class at the beginning of the semester. On an item concerning political parties, for example, one can indicate that one is “a strong supporter of,” “prefers,” or has “a slight preference for the Democratic Party” or has “a slight preference for,” “prefers,” or “is a strong supporter of the Republican Party.” Later in the semester, some of these same students signed up for a “first impressions” study, and the experimenter, unknown to the participants, filled in the survey for the bogus stranger to express views that were between 0 and 100 percent similar to those of the participant. Participants then indicated their impression of the person on the Interpersonal Judgment Scale. The scale includes ratings of the stranger’s intelligence, knowledge of current events, adjustment, morality, and their liking and desire to work with the stranger. The “liking” and “work with” items are added together to measure attraction. Experiments found a linear relationship between the proportion of similar attitudes and interpersonal attraction, sometimes referred to as the *Law of Attraction*.

The basic paradigm is easily adapted. For example, the method has been used to examine voter reactions to the opinions expressed by political candidates about whom additional information was also varied. Many different kinds of similarities have been studied, including similarity of economic status, academic ability, and teaching expertise, among others. Beyond similarities, the paradigm has also been used to examine the importance of such factors as gender, expressiveness, physical attractiveness, earning potential, reciprocal liking, and so on. The technique provides a standardized context within which to compare the effectiveness of virtually any interpersonal characteristic on attraction and dislike. For example, a meta-analysis of studies varying physical attractiveness of opposite-sex bogus strangers found that women valued attitude similarity in men significantly more than physical attractiveness, whereas men tended to emphasize a woman’s physical attractiveness more than her attitude similarity. In another study, high earning potential was liked in women who were also attractive. In men it was generally liked, but especially when men were unattractive. Such results indicate that

despite limitations regarding realism, the bogus stranger paradigm is capable of uncovering some of the complexities of interpersonal attraction.

The initial effect of attitude similarity on attraction was explained by Donna Byrne using Leon Festinger's observation that attitudes have no objective criterion of correctness so that people must depend on consensual validation. He later invoked the concept of effectance motivation, proposing that agreement may satisfy people's basic desires to be effective. As a test, experiments involving a "crazy movie" intended to temporarily arouse this motive found that moderate levels of confusion did amplify the role of attitude similarity in interpersonal attraction.

Various alternative explanations have also been proposed for the relationship between similarity and attraction, including that dissimilarity rather than similarity is responsible for the effect, that it depends on inferences about reciprocal liking, and/or that it depends on inferred beliefs about the stranger's desirable traits. Although many factors can play a role, attraction to similarity and rejection of dissimilarity appears to be a very basic biological and psychological principle, evident all the way from the cellular level in the immune system to the level of human social groups.

The flexibility of the method and its ease of use have made it a popular procedure in several different fields. One limitation is its lack of ecological validity since bogus strangers can be created with combinations of attributes that do not occur naturally. It also lacks realism so that research participants' ratings may reflect information about persons rather than experience with them. However, the results often go beyond people's implicit theories of attraction. For example, in a study in which physical attractiveness was found to be quite important, participants believed that it had been the least important factor in their ratings.

In contrast to these limitations, the paradigm has several advantages. Chief among these is the versatility and experimental control it provides. Such standardization holds out the promise of replicable and cumulative findings. In addition, the method affords quantitative treatments of the independent variable of attitude similarity and of the dependent variable of attraction. As a result, quantitative modeling can be done to test competing models of attraction.

When the method was developed, research on liking mainly involved impression formation experiments focused on the likability of combinations of trait adjectives. In the bogus stranger paradigm, by contrast, people believed they were actually seeing another person's expression of opinion, often with background information about them. This minimal realism could thus elicit affective as well as intellectual reactions to the bogus stranger. On this basis, accounts of attraction were increasingly framed in terms of affect and emotion, factors that had little presence in social psychology at the time.

The fact that interpersonal attraction involves emotion now seems clear; but in the 1970s, explanations focused on the role of beliefs rather than feelings about attitude objects. Indeed, it was another decade before the successor to the attraction model, the affect-as-information approach, appeared on the scene. It was stimulated by earlier bogus stranger experiments that included mood induction procedures for the first time in social psychology. Investigators could then manipulate affect independently of cognition by using films and other mood inductions, procedures that have become staples in contemporary social psychology.

BORDERLINE PSYCHOPATHOLOGY IN RELATIONSHIPS

Borderline personality disorder (BPD) is characterized by a pervasive pattern of instability of interpersonal relationships, self-image, and emotions. BPD affects 1 to 2 percent of the population, and core features of the disorder may occur in up to 5 percent of community samples. Because BPD is characterized by extreme and unstable emotions and behaviors, the relationships of people with BPD can similarly be intense and chaotic. This entry summarizes core features of BPD, the impact of these on close relationships, and findings regarding clinical interventions.

Features of BPD

The problems of BPD generally fall into four categories: (1) emotion instability, characterized by emotion sensitivity, emotion reactivity, and a slow return to emotional baseline; (2) behavioral impulsivity (including suicide attempts or threats), particularly when emotionally dysregulated; (3) dichotomous thinking—as in viewing persons as all good or all bad or as holding self-views that are similarly extreme; and (4) problems in relationships, including fears of abandonment, high levels of dependence on others, and high levels of anger. Persons with BPD vary in the kinds of problems they have. Being very emotional describes a common shared characteristic, whereas other features of BPD may vary considerably from person to person. Other problems and psychiatric diagnoses commonly co-occur with BPD—including depression, anxiety disorders, substance abuse problems, post-traumatic stress disorder, and eating disorders.

The causes of BPD are not well established. Although BPD itself is not inherited, certain components of BPD (such as a tendency toward impulsivity) do have a hereditary component. The best evidence seems to suggest that BPD results from a complicated interplay between a person's temperament as a child (e.g., high levels of emotion sensitivity, reactivity, and slow return to equilibrium) and how people in the family and social environment (e.g., peers, teachers) respond to the emotional child over time. In addition, persons with BPD are more

likely than the norm to have been physically or sexually abused as children (although less than 10 percent of abused children go on to develop BPD).

Impact of BPD Problems in Close Relationships

There is more conflict in couples and families in which someone has BPD. Partners, parents, and other family members can be overwhelmed by having a loved one who is impulsive, has intense or unstable negative emotions, and often engages in dangerous behaviors (such as suicide attempts or other self-harm). Family members of someone with BPD report high levels of burden, depression, loss, and grief. Fears of abandonment, rejection sensitivity, and dependency in relationships contribute to demands for attention, commitment, and time together; simultaneously, high levels of impulsivity, shame, anger, depression, and suicidal behavior can push loved ones away. Interpersonal chaos and confusion are common results.

Not only do relationship difficulties result from problems associated with BPD, but also they may also contribute to those problems. For example, the quality of current relationships is a moderate predictor of prognosis. Specifically, invalidation of emotions, beliefs, desires or other expressions by parents, partners, and others can initiate (or exacerbate) emotion dysregulation, which may lead to destructive behaviors (self-harm, aggression, and other impulsive acts). Invalidating responses include criticizing, minimizing, or rejecting the valid feelings and desires of the individual. Moreover, disturbances in relationships (e.g., rejection, severe invalidation) may trigger suicide attempts and other self-harming or impulsive behaviors.

One reason that the relationships of persons with BPD may be more chaotic may have to do with the discrepancies in thinking within their families. Persons with BPD often see themselves as more stable and their relationships more negatively than their partner's and parent's views them. This may be due to distortions on the part of the person with BPD that result from high levels of emotion sensitivity or dysregulation, or it may be due to specific biases or distortions of their loved ones. In either case, their abilities to view their strengths, problems, and interactions in ways that are congruent with

their loved ones' views lead to more conflict and interfere with interpersonal closeness. Although conflict and anger are common in the relationships of people with BPD, having high levels of emotional connection and emotional involvement are beneficial and can be used to create more successful individual and family therapies for people with BPD.

Interpersonal Treatments for Persons with BPD

Evidence-based treatments specific to families having a member with BPD have only recently been developed. Dialectical Behavior Therapy (DBT) for adolescents includes a component for parents and has been adapted for couples having a partner with BPD. These and a variety of other family applications of DBT have been shown to be helpful both to the individual with BPD and to family members. In addition, family skill groups and therapy have been developed from a variety of perspectives and can be added to the treatment mix regardless of what other treatments the individual with BPD might receive. Finally, Family Connections groups (through the National Education Alliance for BPD), led either by professionals or trained family members, have been shown to help family members reduce their experience of burden, grief, and depression and increase their reports of mastery and empowerment.

BOREDOM IN RELATIONSHIPS

Relationship boredom refers to a specific type of relationship challenge in which one or both members of a couple feel that the relationship or the partner has become uninteresting, unexciting, and lost all feeling or “spark.” Unlike traditional obstacles in relationships (such as arguments, betrayal, and so on) that focus on the presence of negative emotions and negative relationship processes, relational boredom is best thought of as an absence of both positive and negative affect and an absence of motivation. Although all interpersonal relationships are susceptible to habituation or boredom, it is likely to be most perilous for romantic and marital relationships. Despite its potentially serious impact, there is very little research on boredom specific to relationships. This entry describes current research on relationship boredom, its underlying concepts and definition, potential causes and consequences of relational boredom, and methods for reducing it.

Stephen Vodanovich, a principal researcher on boredom in general (not relationship specific), and his colleagues have defined boredom as a low-arousal, dissatisfying state that is attributed to an inadequately stimulating situation. Boredom may also be viewed as a personality trait, strongly affecting some people but only weakly (or not at

all) affecting others. In the relationship field, Shelly Gable and Harry Reis have situated relational boredom within a two-dimensional framework of relationship processes as representing the low ends of positive and negative relationship processes (affective and motivational). Rather than consisting of a specific affective or motivational state, boredom appears to coincide with a lack of highly affective states and motivational goals. That is, someone feeling bored is unlikely to experience high-arousal emotions (such as rage or exhilaration) or have strong motivation to achieve goals or avoid undesirable consequences.

The account of relational boredom as a lack of something is consistent with current relationship research and with assessments of layperson's conceptions of boredom. For example, self-expansion theory suggests that people are most satisfied in relationships when they are continually expanding their sense of self and their perceptions of the partner and relationship. Early in a relationship, expansion is rapid and associated with feelings of excitement. Eventually, though, as couples become more accustomed to each other, expansion slows and the consequent loss of this rapid self-expansion may result in a loss of excitement, a lack of growth in the relationship, and an onset of boredom. Studies investigating laypersons' concepts of boredom have identified several central features including lack of interest, lack of excitement, loss of newness, feeling nothing, and lack of motivation. In contrast, the presence of negative qualities (e.g., arguing) is not identified as central to relational boredom, suggesting that people characterize boredom as representing a "lack of something," either positive or negative, in their relationship.

Boredom, essentially, may be viewed as an outcome of the process of habituation that occurs when a person becomes accustomed to a given stimulus after repeated exposure, which thereby becomes less interesting or exciting. For romantic relationships, this may be represented as a lack of change or growth in the relationship or as an absence of tending to a partner's needs required for sustaining relationship satisfaction. Partners who routinely engage in the same activities together and who always act (and react) predictably toward each other could become overly comfortable with the repeated habits and end up bored.

It is well documented that satisfaction declines sharply in the early years of marriage; however, research has not found that this drop in satisfaction is necessarily caused by increased conflict. This is notable as, currently, much clinical work emphasizes the presence of negative processes (such as conflict) as the central challenge that couples face. It is not known if boredom is the cause of this decline, but many relationship theorists and therapists have suggested it as a probable candidate. Although some individual differences in boredom proneness have been identified in other areas (e.g., in work and school performance) and there is evidence that relational boredom is associated with increased perception of attractive alternatives, other potential effects of boredom in interpersonal relationship research are much less clear.

Arthur Aron and his colleagues find that couples who engage in novel and challenging shared activities report increased satisfaction and decreased boredom. In contrast, couples who engage in routine, simple, or merely pleasant (rather than exciting) activities with each other do not report such changes. This further suggests that relationship boredom is associated with an absence of highly arousing affect and provides an interesting method for combating habituation in the relationship and reducing boredom. Mihály Csíkszentmihályi's research on the experience of flow introduces another potential relief from boredom based on motivational goals. Put simply, flow is an experience in which a person becomes completely focused on an activity that is challenging and intrinsically rewarding and that causes feelings of great enjoyment and fulfillment. Arguably, a relationship in which each person is intrinsically fulfilled by the other might result in a sort of relationship flow, producing enjoyment and satisfaction for the couple and reducing boredom. Taken together, perhaps the most effective means of alleviating relationship boredom is to focus on increasing positive shared activities between couples that involve novelty and challenge and are intrinsically interesting.

BOSTON COUPLES STUDY

The Boston Couples Study was a pioneering longitudinal study of American dating couples. Launched in 1972, the study initially followed college student couples for 2 years, as they moved toward long-term commitment or breakup. The study was notable for its integrative use of research methods—survey research, psychometric scaling, laboratory experiments, and in-depth interviews. It addressed a wide variety of topics, including the development of love and commitment, power and decision making, sexual attitudes and behavior, and the causes and consequences of breaking up. The study also investigated the interplay of sex-role attitudes and relationship development at a time when the roles of men and women in families and the workplace were being questioned.

The study was directed by Zick Rubin, then an assistant professor in Harvard's Department of Social Relations, and codirected by Anne Peplau and Charles T. Hill, then graduate students in social psychology. Many other graduate students and staff members in social, personality, developmental, and social psychology joined in the research.

The researchers recruited participants by mailing letters to random samples of sophomore and junior men and women attending four diverse colleges in the Boston area and by advertising on one of the campuses. Both members of 231 couples who were "dating" or "going together" independently completed extensive questionnaires about themselves

and their relationship. The questionnaire included sections on the history of the relationship, activities as a couple (including decision making and sexual behavior), and psychological scales—some of them developed by the researchers—of such variables as love for the partner, attitudes about sex roles, and self-disclosure. Some of the couples were interviewed about their relationship, and some took part in laboratory studies of interaction. Follow-up questionnaires assessed the development—or decline—of the relationship over the course of 2 years, and additional follow-up surveys were conducted 15 and 25 years later. Some of the major findings included the following:

- After 2 years, about 19 percent of the couples had married, 34 percent were still dating or going together, and 47 percent had broken up. Couples in which the two partners were equally involved were more likely to stay together than couples in which one of the partners was more involved than the other. Both women's and men's scores on Rubin's Love Scale also predicted the staying power of relationships.
- Among the couples who were not equally involved, the partner who was less invested in the relationship was likely to have more say in decisions made by the couple, illustrating what sociologist Willard Waller had called *the principle of least interest*. The woman's sexual attitudes and experiences were more important than the man's in shaping a couple's sexual behavior.
- The pattern of data supported the generalization that men tended to fall in love more readily than women, but women tended to fall out of love more readily than men. More specifically, women were more cautious than men about entering into romantic relationships, more likely to compare the present relationships to alternatives, more likely to end a relationship that seemed ill-fated, and better able to cope with rejection.
- Fifteen years later, 73 of the 231 couples had married their original partners and 50 of these couples were still married. The best predictor of relationship survival over 15 years was the same as the best predictor of survival over 2 years: Couples who were equally involved in the relationship when they first took part in the study were the most likely to remain together after 15 years.

The Boston Couples Study provided a portrait of American couples located at a particular time, place, and social context. The participants were college students born in the early 1950s. But beyond depicting Northeastern baby boomers, the study has had a significant influence on the presuppositions and methods of subsequent researchers. The study demonstrated the potential value of quantitative longitudinal studies of relationships and provided examples of measurement tools that have been profitably used or subsequently developed by others. The study was also instructive in its emphasis on the interplay of individual variables (individuals' attributes, attitudes, and emotions) and dyadic variables (the couple's patterns of behavior and the unfolding of their relationship).

The Boston Couples Study researchers also paid special attention to probing the impact of the study itself on the participants' relationships. It became clear, for example, that questions about people's relationships may promote discussion, disclosure, and sometimes conflict between the partners. Most participants concluded that any effects of the study on their relationship were for the better—whether it helped to cement the relationship or hastened its dissolution. But at least some of the participants felt that the study affected their relationships in ways that they had not bargained for. For both methodological and ethical reasons, the Boston Couples Study researchers urged future researchers to remain sensitive to the potential effects of their research on the relationships they study.

BULLYING

This entry provides a brief yet comprehensive overview of bullying. The point is made that, at root, bullying is a social phenomenon that cannot be understood solely in terms of particular individuals or particular behaviors. Instead, bullying involves a relationship between specific perpetrators of harm (i.e., the bully) and specific, low-power victims. The entry begins by defining bullying and differentiating it from other types of aggression. The next sections then describe bullies and two groups of victims: passive victims and aggressive victims. The final section focuses on the practical implications of the extant research.

What Is Bullying?

Popular conceptualizations of bullying are often misleading. For example, common myths suggest that any use of aggression constitutes bullying, that bullies are either social isolates or members of deviant peer groups, and that bullying only exists within highly individualistic, competitive cultures. A primary goal of this entry is to debunk these and other myths.

First, bullying cannot be defined by a specific group of behaviors such as teasing, threatening, and manipulating social relationships, nor does simply enacting these behaviors make one a bully. To the contrary, bullying is distinct from other, more general categories of aggression in that it is characterized by (a) repetition over time, (b) an imbalance of physical and/or psychological power between the bully and victim, and (c) an intention

to harm the victim. Bullying therefore involves a behavioral interaction and over time, a relationship in which bullies repeatedly inflict harm on specific, lower-power victims.

Second, bullying does not occur in isolation. To the contrary, observational studies show that peers are present in 85 percent of bullying episodes and that peers often play a supporting role in reinforcing some bullies for aggressing against some, but not all, victims. For example, research by David Perry and colleagues shows that classmates' views of bullies depend on who they victimize. Only some victimization is viewed negatively, while aggression against other children is ignored, tolerated, or—at worst—rewarded. For bullies, such support means that targeted victimization may involve only minimal costs and in some cases, substantial benefits in the form of social support and elevated peer status. Ironically, aggressive victims may also accrue some benefit from the bully–victim relationship. Social dominance theory and research by Anthony Pellegrini and colleagues suggests that victims of bullying may themselves target weaker peers to gain status and notoriety among peers. Such findings suggest that status-related contests may underlie cycles of aggression among bullies and victims alike.

Third, bullying is not unique to some cultures. To the contrary, international research shows that bullying is a common and persistent problem around the world, with Japan, Norway, the United States, and the United Kingdom showing no significant differences in the frequency of bullying across urban, suburban, and rural settings. Research also shows that the bullying problem develops according to a similar timeline in different parts of the world, most likely driven by age-related patterns of peer interaction and school organization. Specifically, the bullying problem first emerges in elementary school and then becomes particularly acute, at least in terms of frequency and severity, in middle school or junior high.

Taken together, these findings suggest that bullying cannot be attributed to particular cultural attributes or even to particular demographic settings. Bullies do share some individual qualities that distinguish them from peers, however, and this entry's next section reviews what is known about these characteristics.

Bullies

Bullies represent about 7 to 15 percent of the sampled school-age population. Generally speaking, these individuals represent a subset of proactively aggressive children who tend to formulate instrumental goals (e.g., to intimidate and dominate a peer) and then to choose an aggressive response to achieve that goal. Socialization research suggests that the families of some bullies are conflictual and that parents often use aggression to manage behavior. Following a social learning model, this view suggests that, after consistent exposure to adults using power assertive strategies to solve social problems, some aggressive youth learn that aggression can be used instrumentally in the service of obtaining desired goals, securing reinforcement, and in general, getting things done. For example, older youngsters may use physically assertive behaviors as a public display of dominance or social status over weaker peers. Observational research by Pellegrini and associates supports this claim, showing that preschoolers and early adolescents alike initiate physical and verbally aggressive bouts with peers in an effort to gain status, especially during the start of the school year and following transitions from elementary to middle school.

Peer Acceptance

Bullies' proactive aggression often results in rejection from peers, especially in the absence of concomitant cooperative and other prosocial behaviors. By default, therefore, some bullies tend to be popular with similarly aggressive youth, as individuals sharing similar behaviors, goals, and values tend to belong to the same peer group. Evidence also suggests that, over time, individual members of peer groups become more similar in levels of aggression. For example, Dorothy Espelage and colleagues shows that, among sixth through eighth graders, both male and female peer groups became more similar over a 1-year period in the amount of self-reported bullying. It is important to note, however, that research does not support the myth that all bullies belong to small, low-status groups of deviant peers. To the contrary, research shows that the acceptability of aggression varies widely across individuals and

classrooms alike. For example, a recent study involving some 3,000 children in 134 first-grade classrooms from four U.S. cities showed that peers rated aggressive classmates positively in high-aggression classrooms and negatively in low-aggression classrooms. These findings suggest that group norms affect the acceptability of individual children's aggressive behavior and so doing provide yet another example why bullying represents a social rather than individual phenomenon.

Social Skills

Building on this last point, it is also a mistake to assume that all bullies are physically powerful but intellectually stupid. To the contrary, research reveals significant heterogeneity among aggressive youth, with some actually being high-status, socially central members of the peer ecology. For example, work by Phillip Rodkin and Thomas Farmer shows that, among fourth-, fifth-, and sixth-grade students, two thirds of aggressive boys and one half of aggressive girls belonged to peer groups whose members were mostly (i.e., more than 50 percent) nonaggressive. This and other research suggests that practitioners should not assume that all bullies are socially unskilled. After all, bullies are not indiscriminate in who they target, tending instead to victimize specific children who do not fight back and who do not receive support from peers. This entry's next section reviews what is known about two groups of victims: passive victims and aggressive victims.

Victims

Passive Victims

Typically, about 10 percent of the school-age population may be described as passive victims. These children tend to be physically slight or frail and, as a rule, tend to withdraw from social activities. Compared to nonvictims, passive victims rarely initiate social conversation and, in response to peer influence, are also more submissive. Passive victims of bullying are also at greater risk for subsequent psychological disorders, especially internalizing problems such as anxiety, depression, and loneliness. Importantly, research

also suggests that, in the absence of bullies, passive victims tend to blend into classrooms like other youngsters and that these victims are not typically targets of aggression after leaving school.

Aggressive Victims

Another 6 to 10 percent of the school-age population is considered aggressive victims, at times also described as *bully-victims* and *provocative victims*, terms reflecting the duality of being the target of aggression while at the same time inflicting harm in response to peer provocation. Like passive victims, aggressive victims are systematically bullied by their peers, but they also react aggressively, not instrumentally, to bullying and provocation. Thus, aggressive victims display a hostile style of social interaction and are described by their peers as those who start fights, say mean things, get mad easily and get picked on, teased, and hit or pushed. Given such descriptors, it is perhaps not surprising that aggressive victims are the most rejected members of their peer group and that they are at substantial risk of subsequent psychological disorders in the form of externalizing problems, such as delinquency, truancy, bullying, poor educational achievement, and in extreme cases, suicide. In the extreme, these externalizing problems have been linked to a majority of targeted school violence in the United States from 1974 to 2000, with the Secret Service finding that 71 percent of school shooters report being chronically bullied in school.

The socialization histories of aggressive victims are, like bullies, typified by power-assertive interactions. Aggressive victims also describe their parents as inconsistent, sometimes abusive, and low in warmth and parental management skills—the results of which is that they tend to view the world as a hostile and untrustworthy place. Consequently, aggressive victims also tend to attribute hostile and aggressive intent to peer interaction. Some researchers argue that these biases may, at some level, contribute to a self-fulfilling prophesy of sorts, as aggressive victims attribute hostile and aggressive intent to peer interactions, and some peers (e.g., bullies) in turn target aggressive victims for ridicule and abuse.

Practical Considerations

In summary, given the ubiquity of bullying and the terrible harm it inflicts on children, schools, and communities alike, it is easy to see why it is such an important issue for educators, parents, and anyone concerned with protecting children and optimizing their school experiences. Such concern must be matched with research-based interventions, however, and this last section emphasizes some of the practical implications of existing knowledge about bullying.

First, research emphasizes unequivocal condemnation of bullying among teachers, administrators, parents, and community members alike. As argued by Dan Olweus and others, literally the entire community must be involved at some level to ensure that the status-enhancing facets of bullying are replaced by uniform condemnation. Thus, classrooms and schools must be consistent in their policies and attitudes toward bullying and avoid creating the conditions in which peers' status-related comparisons are emphasized.

Second, research also demonstrates the necessity of adequate adult supervision, especially during unstructured time and in nonacademic areas of the school such as in the cafeteria, hallways, and bathrooms and during recess. Bullies are systematic both in who they target and when, the implication being that adults must maximize the likelihood of negative consequences and minimize the possibility of social reward in the form of peer group visibility. School transitions (e.g., from primary to middle school) and other disruptions of student relationships are particularly risky times for elevated aggression and victimization, as these transitions by definition disrupt existing peer relationships and invite renegotiation of the status-related contests characterizing bullies and victims alike.

Third, practitioners are reminded that evidence-based accounts of bullying hardly conform to popular stereotypes of bullies. Specifically, bullies are not necessarily male, physically powerful, and

intellectually weak. Boys may be identified as bullies more often than girls, but girls are also involved in bullying, either as perpetrators themselves (especially with relational aggression), as bystanders, or as supporters of some aggressive boys. Likewise, bullies are not necessarily rejected by peers nor are they inevitably relegated to low-status, peripheral groups. Adherence to these myths risks overlooking the variety of ways in which bullies integrate and rely on mainstream social networks to target their victims and reap their social rewards. Adhering to these myths also risks perpetuating the terrible harm inflicted on passive and aggressive victims alike. For aggressive victims especially, history suggests that such harm only begets more harm, some of which escalates in horrific scale.

CAPITALIZATION

Many languages and cultures have a proverb that is a variant on the theme, “a joy shared is a joy doubled.” Most people believe that there is something desirable about sharing positive events with others, a belief echoed by researchers who have found that people actively tell other people about these positive events—a process called *capitalization*. This entry discusses the role that capitalization and the responses that others have to capitalization attempts play in personal and relationship processes.

Capitalization in Everyday Life

Several studies on naturally occurring capitalization have asked people to report on the best thing that happened to them each day over a period of time, such as over 2 weeks. More often than not (up to 80 percent of the time), people tell at least one person about the best thing that happened to them that day. Of course, people are more likely to capitalize about important events, but capitalization about minor events is also common. More importantly, these studies also confirm common intuitions that there are benefits to sharing positive events with others. These benefits included increases in positive emotions, greater life satisfaction, increased quality of interpersonal relationships, greater memory for the event itself, and higher value placed on the event. These benefits

occur in addition to the benefits experienced from the event itself.

These benefits are contingent, however, on how the person or persons with whom the event is shared reacts. That is, some responses to capitalization are associated with benefits whereas others are associated with no benefits or even harm. It seems that the responder plays a key role in the capitalization process, but with whom do people share their positive events? Typically, people tell close others; over 90 percent of the time positive events are shared with spouses or romantic partners, friends, roommates, parents, or siblings. Only on occasion do people share positive events with acquaintances or strangers.

Responses to Capitalization

When people attempt to capitalize, the close other with whom they have shared the positive event can respond in various ways. The response can range from active to passive and from constructive (encouraging and supportive) to destructive (critical and unsupportive). In terms of activity versus passivity, the responder can show interest and involvement when the event is shared, or the responder can be reserved and distant. In terms of the constructive versus destructive tone, the responder can be encouraging and supportive or negative and unsupportive. By considering variations along these two dimensions, four prototypes of responses to capitalization attempts can be described: active-constructive, passive-constructive, active-destructive, and passive-destructive.

Active-constructive. An active-constructive response is one that expresses excitement about the positive event and conveys positive regard toward the person who disclosed the event. An active-constructive responder will often ask questions about the event, highlight important aspects of the event, and elaborate on its potential implications. The active-constructive responder expresses enthusiasm, happiness, or pride.

Passive-constructive. A passive-constructive response is one that may seem positive or supportive but is delivered in a tempered and subtle manner. These responses are often pleasant but quiet exchanges involving few questions about the event and little if any elaboration on implications of the event for the capitalizer.

Active-destructive. An active-destructive response is one in which the responder is keenly and energetically involved in the exchange. However, this response minimizes the importance of the event, focusing on potential unfavorable implications of the event or even reinterpreting the event as negative.

Passive-destructive. A passive-destructive response is one in which the responder does not acknowledge the event being disclosed. This response conveys little or no interest in the positive event, and the responder may change the subject completely or talk instead about an event of his or her own.

Consider the following example: Jane returns home from her internship in a law firm and breathlessly tells her husband, Jack, that she was assigned to assist with the firm's case for its most prestigious client. An active-constructive response from Jack might be, "Wonderful news! I knew you had the natural skills and drive to be a great lawyer. This is just the tip of the iceberg; your career is going to be full of days like this. What is the case about, and what is your role in it?" A passive-constructive response might be a pleasant smile followed by, "That's nice, dear." An active-destructive response might be, "Wow, I bet the case is complicated and difficult. Do you feel capable of working on it? I hope you don't screw up. I wonder if none of the other interns wanted to case; it is probably technical and boring. You will probably have to work

even longer hours this month." And a passive-destructive response might be, "You won't believe what happened to me today," or "What movie should we see this weekend?"

Research has shown that only active-constructive responses are beneficial. When listeners respond in an active-constructive manner, the capitalizer experiences more benefits, such as more positive emotion, greater well-being, and increased memory for the event. However, when a person attempts to capitalize and receives a passive or destructive response from others, he or she does not experience these benefits and may instead experience distress and other negative emotions.

Responses to capitalization also play an important role in the quality of the relationship between discloser and responder. Research has shown that the manner in which spouses or dating partners typically respond to each other when one shares a positive event is associated with relationship quality. People who report that their partners typically respond in an active-constructive way also report greater satisfaction, intimacy, trust, and commitment and fewer conflicts than those who report typical passive-constructive, passive-destructive, or active-destructive responses. Research has also shown that the way in which a partner responds to positive event disclosures is distinct from how the partner responds to transgressions, such as when his or her feelings are hurt, and independently predicts relationship quality. In addition, capitalization responses are distinct from how the partner responds to negative-event disclosures (typically referred to as social support). Moreover, capitalization responses predict relationship quality independently, and in some studies, better than social support responses.

This pattern of findings is not limited to self-reports, as observational studies and laboratory experiments have shown. When trained observers code the videotaped behavior of couples or when participants are randomly assigned to receive different types of feedback from experimental confederates, active-constructive responses are associated with personal benefits and better relationship quality. Passive or destructive responses, on the other hand, are associated with negative outcomes for the discloser and for his or her relationship with the responder. The association between active-constructive responding and relationship quality

has also been found in other relationships, such as among parent–child pairs, roommates, and friends.

CAREGIVER ROLE

An increasing number of adults will experience the challenges and benefits of supplying ongoing assistance to others. Individuals who provide care for a sick or frail family member, friend, or neighbor are participating in the caregiver role. This entry reviews the characteristics of individuals who assume the caregiver role, explores the risks and rewards of caregiving, and discusses the implications of caregiving for personal relationships.

Although formal caregivers, typically paid professionals (i.e., nonfamily members), also manage and provide assistance, this entry focuses on informal family caregivers. Informal family caregivers are likely to experience more chances for risks and opportunities for rewards in their personal relationships with care recipients than formal providers do. For example, formal helpers are not likely to have had a previous personal relationship with the care receiver and must begin caregiving as strangers. Further, formal caregivers are paid for their assistance, payment which may create a more distant service provider–consumer type of relationship, at least in the beginning. This does not mean that close bonds are not formed in formal provider–consumer relationships, but the implications of informal

caregiving for family relationships are inherently different from those of formal caregiving relationships because of these situational differences.

Characteristics of Informal Caregivers

Social norms based on a hierarchy of preferences influence who serves as an informal care provider. When spouses are available in this hierarchy of informal caregiving, they are expected to assume responsibilities first, followed by an adult daughter or daughter-in-law, and then other female caregivers (i.e., niece, sister, aunt, or granddaughter). The next relatives in line to assume caregiving responsibilities are sons and other male family members. Although this hierarchy of informal caregivers is well established, recent trends in family interaction patterns indicate that adult children are providing care in greater numbers than ever. Historically, as indicated by the hierarchy of preferences and dictated by traditional definitions of gender roles, females have been more likely than males to assume the informal caregiver role. The difference in life expectancy between males and females, with females living longer than men, is one explanation for this pattern. Another is that many in society have assumed females are better at caregiving and are naturally suited to provide assistance. Recent national caregiving trends indicate, however, that these gender-based expectations have lessened, and emerging evidence points to increasing numbers of men participating in the caregiving role.

The typical caregiver is a middle-aged (i.e., late 40s to late 50s) female who is married and working either full- or part-time. Youth and young adults also assume care-related roles when family circumstances warrant. On average, family helpers complete 20 hours of aid a week and perform a variety of care-related tasks for recipients. Tasks include assisting with activities of daily living (ADLs) and instrumental activities of daily living (IADLs). ADLs include bathing, dressing, eating, and grooming. IADLs include forms of aid such as cooking, cleaning, shopping, transportation, and assisting with finances. Along with completing or assisting with everyday tasks for care recipients, caregivers make decisions about recipients' health and safety. For example, care providers evaluate a recipient's

ability to drive, establish and maintain healthy living environments, and secure proper professional medical aid and financial or legal advice. The amount of time and the specific care-related tasks caregivers provide may increase their chances for experiencing both risks and rewards.

Risks of the Caregiver Role

Risks associated with the caregiver role include negative experiences related to providing aid and harmful impacts on the caregiver–care recipient relationship. Negative experiences consist of caregiver stress and physical, mental, and emotional strain associated with providing help to a family member, friend, or neighbor. In addition, individuals may experience costs associated with their role. For example, financial costs and strains, which include paying for medical expenses and medications and taking time off from work or being distracted during work, are risks of the caregiving role. Further, providing aid to a family member or friend may interfere with maintaining or building other relationships with a spouse or partner, children, other family members, or friends. Other family members and friends may criticize caregivers for their willingness to provide assistance and the way in which they complete care-related tasks for the recipient. Individuals in the caregiving role often feel a sense of burden, stress, and conflict associated with the long hours of caregiving and the demands placed on them to meet the recipient's needs.

Two common experiences of individuals in the caregiving role are caregiver burden and burnout. Caregiver burden is the build-up of stress associated with performing many different tasks under difficult circumstances. Burden experienced by someone in the caregiving role can have multiple sources. For example, a main reason for experiencing stress is the need to balance the competing demands of work, family, and care-related tasks while managing to reserve some time for personal activities. Achieving a balance may be even more complicated when individuals are providing care while they are currently rearing their own children. This situation, often attributed to persons in the “sandwich generation,” can increase the amount of role conflict associated with informal caregiving.

Despite the fact that respite care (i.e., relief from caregiving) is beneficial to the caregiver and the recipient, a second reason why individuals may experience a build-up of stress is that many do not take a break from caregiving. They may feel that getting help from others is too complicated or too disruptive to the recipient's routine, and sometimes recipients resist attempts by anyone but the caregiver to help them. A third reason for care-related stress may be earlier relationship experiences between the provider and the recipient. For example, adult children with a history of difficult interactions with their parents may have continued relational conflict in the informal caregiving situation. Finally, caregiving spouses with unachieved goals for retirement, resentment toward the spouse who needs assistance, and disappointment about how they are spending their time may feel greatly burdened by their role. Regardless of the reasons why individuals experience difficulties, increases in stress and feelings of burden associated with caregiving can have serious implications for the caregiver's health as well as for the quality of the relationship with the recipient.

Caregivers' physical and mental health status may be poorer compared to non-caregiving-aged peers because of the stress and strain experienced in providing ongoing help to a relative or a friend. For example, chronic illness and depression resulting from the emotional turmoil and physical demands of providing assistance are typical experiences of informal caregivers. Female caregivers tend to express more depressive symptoms than male providers. This may result from the tendency for women to approach their role from a more emotional stance, whereas men tend to take a more objective, problem-solving approach to caregiving tasks. Nevertheless, both women and men are susceptible to caregiver burnout.

Caregiver burnout is the physical, mental, and emotional exhaustion that many individuals experience from assisting relatives or friends over a long period of time. As care recipients' functional capacity declines and their need for assistance increases, the demands on informal providers and the risk of caregiver burnout increase. Caregiver burnout is of great concern given the potential health problems (e.g., increase in blood pressure) that individuals may experience and the risk of them becoming unable to continue providing

assistance. When burnout occurs, caregivers' mental and physical health may be worse than that of their care recipients. In this state, they may not be meeting the recipients' needs. As a result, stress associated with caregiver burden, and burnout may lead to abuse, neglect, or even abandonment of care recipients.

Not only are caregivers' physical and mental health in jeopardy, their relationships with their care recipients are likely to be affected as well. The effects depend on the recipients' conditions and the types of aid required. For example, caregivers of persons diagnosed with Alzheimer's disease or a related disorder (ADRD) tend to experience more negative changes in their relationships than helpers of persons with other illnesses. The cognitive decline associated with ADRD not only affects memory in ways that are painful to caregivers (e.g., not recognizing the caregiver or forgetting about their close relationship history), it may also lead to personality changes in the care recipients, inhibit their ability to engage in a meaningful conversation, and produce difficult behavioral problems. This loss of the expected spousal, sibling, parent-child, or friend relationship is extremely stressful for informal caregivers and their care recipients.

Rewards of the Caregiver Role

Focusing on stress associated with the caregiver role, however, represents only one part of caregiving. Providers also report positive experiences and rewards resulting from taking care of a relative or friend. For example, many caregivers enjoy the time spent with recipients and describe their relationships as closer than before intensive caregiving began. Being in the caregiver role may provide opportunities to build or maintain relationships as well as repair damaged relationships and reconnect personal ties that were previously broken or strained. Other rewards associated with providing assistance include knowing the family member or friend is well cared for, seeing the recipient's happiness or contentment, and noticing that the recipient's health has improved or has not declined. In addition, individuals often report gains in their sense of confidence and competence from performing the caregiving role. For example, enhanced

caregiving self-efficacy, or the ability to master new tasks and manage multiple demands, is another reward. Even though some personal care activities (i.e., bathing, grooming, toileting) may be difficult, individuals often find accomplishing them successfully a source of gratification. Many informal caregivers report that they benefit from the rewarding aspects of caregiving. In fact, loss of the caregiver role because of the recipient's improvement or death requires adjustment and reorganization of daily time and activities on the part of the former provider.

CAREGIVING ACROSS THE LIFE SPAN

In 2004, approximately 28 million people in the United States provided personal care to their family members. With the increase in the older population and a decrease in family size, the likelihood of becoming a caregiver will continue to increase in the future. The purpose of this entry is to review research findings on caregiving across the life span. First, this entry will review common caregiving roles that are enacted over the life course, including caring for children with disabilities, aging parents, an elderly spouse, and grandchildren. Next, the entry will examine subgroup differences in caregiving as well as the social structural context of caregiving. Specifically, the entry focuses on gender and racial/ethnic differences in caregiving and how demographic and social structural changes have affected caregiving arrangements within and across families.

Caregiving Experiences Across the Life Span

Caring for Children With Developmental Disabilities or Mental Illnesses

In early to mid-adulthood, many individuals become parents and take care of their children. Caregiving for children can be particularly challenging if children have chronic conditions such as developmental disabilities or mental health problems. In general, developmental disabilities are diagnosed at the child's birth or in early childhood, whereas mental illnesses tend to be diagnosed during the child's adolescence or early adulthood. Thus, caregiving responsibilities for children with disabilities begin at different stages of parents' lives. However, with the increase in the life expectancy of both parents and adult children with disabilities, it is becoming more common for parents to continue caring for these children even into old age.

Not only do parents of children with developmental disabilities or mental health problems bear the objective burdens of care, such as providing help in daily activities and managing their child's problematic behavior, but also they must deal with other problems associated with children's disabilities, such as additional financial burdens and

emotional stress associated with the stigma of disabilities.

Parenting a child with disabilities takes a toll on parents' health and mental health. Parents of children with developmental disabilities or mental illness experience more physical symptoms and higher levels of depression than parents with non-disabled children. Nonetheless, variations exist in the extent to which children's disabilities lead to poor health and mental health among parents. A child's problematic behavior and poor health of the parent increase caregiving burden, whereas a better parent-child relationship leads to greater caregiving satisfaction.

Recent studies have examined the impact of having a child with disabilities on older parents' well-being, as caring for children with developmental or mental health problems, has become a lifelong responsibility for some older adults. According to Marsha Seltzer and her colleagues, parents in their mid-30s and early-50s of children with developmental disabilities have less frequent contact with friends than parents of the same age of unaffected children, although the difference at the later age is less pronounced. Parents in their mid-30s, but not in their early 50s, of children with mental health problems experience greater physical symptoms as well as elevated levels of depression and alcohol symptoms than parents of the same age of unaffected children in.

Although caring for children with disabilities yields negative health consequences for both young and old parents, compared to younger parents, older parents are less negatively affected by their children's disability in part because they have had time to adapt to the challenges of their child's special needs.

There is a significant within-group variation in parental adaptation to children's disability among older adults. Several factors account for this variation. For example, research by Rachel Pruchno found that caregiving satisfaction increases when care-receivers express higher levels of affection to caregivers. As noted by Pruchno and colleagues, positive appraisal of caregiving increases when the quality of the relationship between the caregiver and care receiver is high, whereas, according to S. A. Pickett and associates, it decreases when the caregiver perceives greater caregiving burden.

Caring for Older Parents With Cognitive Impairment or Chronic Health Problems

Another common caregiving responsibility in midlife is the provision of care to aging parents who have cognitive impairments, chronic health problems, or other age-related diseases or disabilities. After one's spouse, adult children are the most important sources of support when older people are in need. In particular, daughters, especially eldest, are most likely to have the primary responsibility of caregiving for aging parents.

Like other caregiving responsibilities, caring for aging parents is both stressful and rewarding. It is stressful in that adult children have to balance the time they spend caring for their parents with their other responsibilities at the workplace and at home. Caring for elderly parents also tends to bring emotional distress to both care recipients and care providers. Feelings of dependence and the loss of autonomy may be difficult for older parents, and adult children may be stressed about the shift in the kinds and amounts of help exchanged within the parent-child relationship. However, caregiving and receiving relationships may also promote affection, gratitude, companionship, and cooperation between aging parents and their adult children.

Caring for aging parents has implications for caregivers' health and mental health. Family caregivers of cancer patients often experience elevated levels of depression, anxiety, and burden. Compared to demographically similar noncaregivers, caregivers of persons with Alzheimer's disease tend to show greater health risks and poorer self-reported health. They also experience higher levels of depressive symptoms and higher use of psychotropic drugs than noncaregivers.

Despite the negative consequences of caregiving, there are rewards of providing care for elderly parents. Caregiving children report positive feelings, a sense of satisfaction and feelings of growth, and strengthened intergenerational ties. Adult children with a high level of mastery, defined by Leonard Pearlin and colleagues in "The Stress Process" as "the extent to which people see themselves as being in control of the forces that importantly affect their lives" (p. 340), tend to adjust better to the stress of caregiving.

Caring for an Elderly Spouse With Cognitive Impairment or Chronic Illness

With the increased likelihood of experiencing chronic illnesses or degenerative diseases, older adults are more likely to need care than younger adults. Out of the over-10-million Americans who need long-term care, approximately 63 percent are persons ages 65 and older.

One of the most common caregiving arrangements in later life, especially for women, is spousal caregiving. Wives tend to take the caregiving role for a longer period of time than other family members and are less likely than other caregivers to place their husbands into nursing homes. Furthermore, because of the central role of the marital relationship, the impact of caregiving is usually more pronounced for spouses than for adult children. Specifically, wives experience a greater decrease in well-being than daughters after entering the caregiving role, although spouses and adult children in shared households experience similar levels of care-related strain.

Spousal caregiving has a negative impact not only on psychological well-being but also on physical health and mortality. Those who experience greater caregiver strain tend to have poorer perceived health and increased health-risk behaviors. Furthermore, spousal caregivers who experience emotional stress have a higher risk of mortality than noncaregivers their age, after taking into account differences in sociodemographic status. Caregiving strain among spousal caregivers increases with the degree of the care-receiving spouse's impairment, which in turn leads to caregivers' poorer perceived health and increased health-risk behaviors, as well as to increased anxiety and depression.

Grandparents Giving Care to Grandchildren

Many older adults provide important caregiving support for their grandchildren. Approximately 2.4 million people in the United States are primary caregivers for their grandchildren for various reasons, such as the parents' substance abuse, incarceration, mental illness, and illness with HIV/AIDS.

The likelihood of becoming a caregiver for grandchildren varies by race and ethnicity. According to the 2000 Census, 2.5 percent of non-Hispanic Whites, 8.2 percent of African Americans,

8 percent of American Indian and Alaska Natives, 6.4 percent of Asians, and 8.4 percent of Hispanic or Latino adults ages 30 and over lived with their grandchildren. Approximately 30 percent of African-American grandmothers have reported that they have been a primary caregiver for their grandchildren at some point.

Although grandparents' provision of care to their grandchildren is a source of substantial help to vulnerable families, similar to other caregiving experiences, this assistance comes with personal costs. Compared to noncaregiving peers, grandparents who are primary caregivers of their grandchildren experience higher levels of functional limitations and depression as well as lower levels of self-rated health.

Subgroup Differences in Caregiving and Caregivers' Well-Being

Gender Differences

The responsibility of caregiving is often disproportionately distributed between men and women. Wives and daughters spend greater time than husbands and sons providing care to their spouses and parents, even after taking employment status into account. Mothers of children with disabilities provide more hours of care and more types of support than fathers do. According to life course theory, this gender disparity in caregiving is largely due to lifelong gendered patterns of socialization and cultural norms.

Different levels of involvement in caregiving between men and women lead to a gender discrepancy in both objective and subjective levels of caregiving burden. Baila Miller and Lynda Cafasso conducted a meta-analysis of 14 studies of gender differences in caregiving and found that women tend to report higher levels of emotional distress and greater caregiving burden than men. Several other studies have confirmed this conclusion. However, male and female caregivers do not significantly differ in their physical health and long-term emotional health.

Despite gender differences in several caregiving outcomes, the determinants of these outcomes tend to be similar for male and female caregivers. For example, among mothers and fathers of children with disabilities, the living arrangement of the child

with a disability, the parent-child relationship quality, and the type of disability were significant determinants of caregiving burden, satisfaction, depression, and life satisfaction for both mothers and fathers, suggesting that similar mechanisms explain the stress process.

Whereas past research focused on investigating gender differences in key caregiver outcomes and the mechanisms explaining these differences, recent studies illustrate unique challenges that male and female caregivers face. Betty Kramer and Edward Thompson explained that men report more anxiety in handling multiple caregiving demands and are not familiar with using social service agencies. On the other hand, female caregivers often experience difficulties in balancing work and caregiving responsibilities. Men and women are also known to show different coping styles—men tend to use more problem-focused coping, and women tend to use more emotion-focused coping.

Racial and Ethnic Differences

Some caregiving arrangements are more common among certain racial/ethnic groups than others. For example, as noted, grandparent caregiving is more prevalent among African Americans than among non-Hispanic Whites. However, several studies show that caregiving has more negative effects on White caregivers than on African-American caregivers.

Families from different racial/ethnic or cultural backgrounds tend to vary in their functions and norms as well as in their demographic characteristics, such as fertility, mortality, residence, and marriage. These varying demographic or structural characteristics of the family contribute to differential caregiving experiences. For example, according to Pruchno, higher levels of caregiving satisfaction among African-American mothers of children with chronic conditions can be explained in part by racial differences in the rate of coresidence with children. In her study, she found that African-American mothers ages 50 and over were more likely to live with their children with disabilities than White mothers, and those who coresided with their children with chronic conditions provided more help and felt greater caregiving satisfaction.

Different cultural or spiritual resources across various racial/ethnic groups also exert a significant

influence on caregiving experiences. On average, members of ethnic-minority groups are more closely embedded in extended families and report more spiritual or religious resources than White caregivers. These resources can provide various forms of support to caregivers.

In a 20-year review of caregiving research, Peggye Dilworth-Anderson and her colleagues summarized previous studies on racial/ethnic differences in caregiving in four domains: social support, negative effects of caregiving, coping, and cultural influences. According to their review, caregivers from minority groups have more diverse sources of social support than non-Hispanic Whites and use informal support more frequently than formal support services. In terms of negative effects of caregiving, some studies found higher caregiving burden among White caregivers, whereas others did not find significant racial or ethnic differences. Caregivers of different racial/ethnic groups often rely on different coping strategies and cultural resources to cope with the stress of caregiving. Investigating such differences in caregiving resources as well as in coping strategies could provide important information about the implications of cultural diversity in caregiving experiences.

Changing Historical and Demographic Trends in Caregiving

The role of family in providing care is contingent upon historical and social contexts. In prior times, many people died in midlife from acute illnesses. With the epidemiological transition, people on average live longer, but a great number of people spend the later years of their life with disabilities or chronic illness, thus making caregiving an increasingly important social issue.

Demographic changes in the past few decades have also shaped caregiving experiences. With the increase in life expectancy and the decrease in family size due to low fertility, the number of individuals needing care continues to increase, whereas the number of potential caregivers is decreasing. The increased life expectancy of children with developmental disabilities also influences caregiving prevalence; parents of these children now have lifelong caregiving responsibilities.

Social contexts that influence family caregiving include the availability of formal social services for

frail older adults and people with disabilities, the availability and quality of care in institutions and community-based care facilities, and the available assistance for caregiving families. For example, deinstitutionalization of individuals with mental illness in the 1950s and 1960s, along with a dearth of effective community-based services, has led families to assume more caregiving or care management for adults with physical or mental disabilities.

Competing demands associated with multiple roles is another influential factor on caregiver health and well-being. With the increase in dual-earner households, it has become increasingly difficult for families to carry out caregiving responsibilities for persons with illness or disabilities. Coordinating caregiving tasks along with work schedules and family activities is challenging and can be stressful, especially if workers do not have much flexibility in their jobs. Nevertheless, holding multiple roles sometimes helps protect caregivers from negative outcomes through enhancements in social support and self-esteem.

In conclusion, caregiving is an increasingly common social role, but its distribution varies along racial and gender lines and differs according to the type of kinship relationship between the caregiver and the care recipient. Population-level demographic shifts in longevity and family size will continue to increase individuals' probability of becoming a family caregiver during the life course, with a concomitant toll on caregivers' physical and psychological well-being. In order to reduce the toll taken by caregiving on both caregivers and care recipients, more discussion is needed on how social programs and policies can provide better support for family caregivers.

CASUAL SEX

Casual sex is broadly defined as having sex with someone with whom an individual is not in a committed relationship. Some scholars define casual sex as having sex with someone a person had met the same day, whereas other scholars

study casual sex in specific contexts, such as while people are vacationing, and regard it as having sex with someone a person had met at any time during the holiday. At times, casual sex can occur with acquaintances, friends of friends, or people who are admired from a distance. Although references to the activities that constitute casual sex are often vague, in most cases it is assumed that casual sex involves sexual intercourse. Investigation into casual sex has expanded greatly over the past 20 years, prompted by the need to define the scope of unprotected sex and the circumstances that lead to the spread of sexually transmitted infections and unwanted pregnancies.

The vast majority of research on casual sex uses samples of young adults who have just graduated from high school, who are in college, or who are traveling internationally (e.g., backpackers). The typical age range for high school and college student samples is 17 to 24, and the typical age range for traveling samples is 22 to 35. The prevalence of ever having had casual sex in these samples ranges from approximately one quarter to one third, with rates nearly doubling when the parameters of sex are expanded to “fooling around” in the absence of sexual intercourse. In most samples, more males admit to having had casual sex than females. Research also shows that, relative to females, males have more positive attitudes toward casual sex, go to bars or on vacation with the purpose of finding a casual sex partner, report more pressure to engage in casual sex, and report more positive emotional reactions to casual sexual experiences. Casual sex is especially prevalent in university students who go away for spring break, which is attributed to beliefs that casual sex is common and even expected in this setting, that people will not be judged for their behavior, and that people are away from home and relatively anonymous.

A common motivation for engaging in casual sex for both genders is sexual desire. However, males are more likely to indicate that they engage in casual sex to develop sexual prowess and enhance their social status among their peers, whereas females are more likely to indicate that they engage in casual sex with the hope that a longer-term relationship will develop. The most cited reasons for not engaging in casual sex, even if opportunities are available, include lack of privacy, concern about contracting a sexually

transmitted infection, and excessive drunkenness. Females also report that they refrain from engaging in casual sex because they are concerned that they will feel guilty or that they will be physically harmed. Some research suggests that males often make pacts with one another to engage in casual sex, whereas females often make pacts with one another not to engage in casual sex. This pattern suggests that there are important gender differences in intentions to engage in casual sex in situations where it is conducive to do so.

The most common predictors of casual sex include alcohol use, personality traits such as impulsivity and sensation seeking, peer influence, an expectation that one will engage in casual sex, and prior casual sex experience. Scholars who examine casual sex that occurs on spring break have identified a number of environmental variables that increase its probability, such as sensual music that promotes close body contact on the dance floor at bars and clubs and drinking games that facilitate heavy alcohol use. Some research has found that casual sex is more common among people with lower education aspirations, who are not active participants in religious activities, and who consistently drink alcohol and smoke cigarettes, behaviors which might be indicative of a deviant lifestyle.

Up to 90 percent of people who indicate that they have engaged in casual sex admit that they did so without using a condom. In fact, many people who intend to have casual sex carry condoms with them for this purpose but do not ultimately use them. Barriers to using condoms during casual sex include using alcohol or drugs prior to casual sex, making an impulsive decision to have casual sex, being in the “heat of the moment,” and identifying other strategies perceived as appropriate in assessing risk, such as having a discussion of both partners’ sexual histories. Research shows that many people who have had a casual sexual encounter worry about the possibility of having contracted a sexually transmitted infection.

Scholars have identified additional negative consequences of engaging in casual sex. Across several studies, females who had engaged in casual sex reported guilty about their actions and speculated that it lowered their self-esteem. Males, in contrast, often indicated that they realized afterward they would not have pursued a sexual

encounter with the partner had they not been intoxicated (i.e., wearing “beer goggles”) and that they found themselves in a position where they had to address the fact that the sexual partner wanted to build a relationship with them. Some people are in committed relationships at home but have casual sex while on vacation and regret their decision afterward, even if their partner does not find out about it. Research shows that people who have infrequent casual sex view it as emotionally unsatisfying and report that they prefer sex in committed relationships, whereas people who have frequent casual sex find it enjoyable and look forward to future encounters. Thus, the most negative emotional consequences appear to occur in people with less experience in coping with the aftereffects of casual sexual experiences.

CHANGE IN ROMANTIC RELATIONSHIPS OVER TIME

Romantic relationships develop and change over time. Indeed, romantic relationships have been conceptualized to follow developmental trajectories. In the 1950s, a single developmental trajectory would have captured a majority of the pathways that romantic relationships followed and would have been characterized by dating, engagement,

and subsequent marriage. More than halfway through the first decade of the 21st century, this trajectory can take more diverse forms, and it would be difficult to define the most common trajectory because of the wide variety of types of romantic relationships. For instance, relationships still may develop through the traditional stages of dating, engagement, and marriage. But currently, the developmental trajectories of romantic relationships may be characterized by a period of casual sex in which the relationship may or may not be a formal dating relationship, followed by dating, visiting (defined as often spending the night together but maintaining two separate residences), cohabitation (defined as living together prior to marriage and maintaining no separate residence from partner), and perhaps subsequent engagement and marriage. Thus, the change in relationships over time is marked by two processes: first, the developmental progression of individual romantic relationships, and second, changes in romantic relationship partners (and thus romantic relationships) across the life course.

In this entry, the primary focus is on these processes over the individual life course, but changes are noted across historical time when relevant. The focus is also on heterosexual romantic relationships in the United States, though these processes occur and, in some instances, are changing across many cultures. The entry begins with a review of the dating and predating literatures, continuing with a discussion of cohabiting and marital relationships. The entry ends with a discussion of serial monogamy, or the process of individuals changing their partners over time.

Progression of Individual Romantic Relationships

Social norms and scripts for the courtship process have become more varied over time. Many adolescents and young adults may not go through a formal courtship process that includes dating and betrothal. One increasingly common trend is for adolescents and young adults to have relationships that are nonromantic but sexual. The rising prevalence of these relationships has changed the landscape of dating and courtship. Recent estimates from the National Longitudinal Study of Adolescent

Health have found that 60 percent of sexually active teens have had sex in both romantic and nonromantic contexts. Qualitative work suggests these patterns continue in young adulthood so that college students argue that college campuses are increasingly characterized by a hook-up culture whereby sexual encounters may occur with random people or perhaps with a friend-with-benefits. A friend-with-benefits is a friend with whom a young adult will have multiple and ongoing sexual encounters outside the context of a romantic relationship. Although at any one point in time, a minority of adolescents and young adults may be in these more casual relationships, the percentage that report having experienced them at some point is high. These casual relationships are often a testing ground for both a more intimate relationship with the casual relationship partner and for future relationships as adolescents and young adults mature and learn new skills for making relationships work. For those with relationships that grow out of nonromantic sexual contexts, the transition between friends and dating can be more ambiguous.

Some scholars have argued that relationships that begin in nonromantic contexts have relatively high levels of inequity and more negative consequences in particular for women, while other scholars have argued that they empower women by allowing women to enjoy their sexuality outside the context of a gendered heterosexual relationship. Evidence suggests, however, that women sometimes comply with casual sex because they believe or want the relationship to become a romantic relationship. Thus, women may be more vulnerable in these relationships if they do indeed want it to become romantic. Both nonromantic casual sex relationships and dating relationships are by their nature marked by lower levels of commitment than most coresidential relationships. One way individuals can bolster commitment in their relationship is to increase equity and investments in the relationship. However, in a dating culture where women experience less equity and are in more ambiguous relationships (complicating the ability of women to invest in them), progression to a committed relationship may slow or halt if the woman (or her partner) is able to find more attractive alternatives.

As casual dating relationships develop, couples do move into more committed forms of relationship.

These forms include visiting, cohabiting, engagement, or some combination. Cohabiting relationships in particular affect many adults across the life span. Estimates vary, but among women ages 19 to 44 forming first unions between 1997 and 2001, it has been estimated that nearly 70 percent of first unions were formed through cohabitation rather than through marriage without a preceding period of cohabitation.

Often couples do not have a formal period of engagement prior to moving in together. Indeed, some couples may not discuss the implications of moving in together nor discuss the implications of cohabitation for their commitment to their relationship. Some scholars have argued that most couples slide into cohabitation rather than decide to cohabit. For instance, a couple may be visiting and decide to save money by maintaining a single lease. Many couples may not realize that by moving in together, barriers to leaving the relationship are created. As couples spend more time together in these visiting and cohabiting unions and acquire more joint social and economic capital, they may find it increasingly difficult to leave the relationship, even if it were to be less than satisfactory. Given the pressures to marry that many cohabiting couples experience, as well as the greater likelihood of an unplanned pregnancy, the foundation from which a marriage is built upon may be less solid and more fragile in particular for those couples who begin cohabiting out of convenience and then marry. There is a large body of evidence that links premarital cohabitation to poor marital functioning and stability. On the other hand, couples who cohabit with marriage in mind or because they desire to increase the commitment in their relationship, may build a stronger relationship foundation as they develop strategies for making their relationship work prior to marriage, hence making the transition to marriage easier. Indeed, scholars have also found that spouses who cohabited with plans to marry look similar to those couples who marry without a premarital cohabitation in terms of their marital functioning. Other couples use cohabitation as a testing ground for the relationship to gain a better understanding of the potential of a long-term commitment with their partner, while enjoying lower costs to exiting the relationship should it not work out. Overall, cohabitation does not tend to be a long-term union

for most individuals: about half end within a year, while over 90 percent end within 5 years, and more end by dissolution rather than marriage.

Even though cohabitation rates have risen, marriage is still very much valued in American society. Those couples who do marry tend to enjoy health and social benefits of marriage. Indeed, individuals who are married consistently report higher levels of well-being than unmarried individuals including cohabitators, daters, and single individuals, even taking account of relationship quality. Over time, however, all relationships change, and marital relationships are no exception. Many studies have examined how satisfaction changes across the life course of marriage. Early studies that relied on cross-sectional data found that marital satisfaction declined in the early years of marriage but rebounded after children leave the household; hence, scholars believed marital satisfaction follows a U-shaped curve across the life course. However, more recent work has demonstrated that the U-shaped curve was an artifact of the cross-sectional nature of the data and was driven in part by older cohorts being more satisfied with their marriages than younger cohorts. Thus, more recent work using longitudinal data has found that marital satisfaction declines across the early years of marriage but does not increase following the decline.

Another critique of the research on the change in marital satisfaction over time is that because of its primarily sociological, large-scale nature, little effort was made to find subgroups of married couples who do not experience declines in marital satisfaction over time. Recently, scholars have used new methods that specialize in finding subgroups in data and have found that there are subgroups of married couples who remain highly satisfied with their marriage over 20 years. This subgroup accounts for about 40 percent of couples in the longitudinal Study of Marital Instability Across the Life Course. A second subgroup, also accounting for about 40 percent of couples, remained around the median of marital satisfaction across time, declining slightly in the early years of marriage and then increasing later. A final subgroup was found, representing about 20 percent of the sample, which began with a lower level of marital satisfaction and experienced a more precipitous drop across the early years of marriage but which

rebounded somewhat in later years, though never to the levels of satisfaction that the more highly satisfied groups experienced. This research needs to be replicated, but it points out that all marriages, and indeed all relationships, do not change uniformly over time.

Serial Monogamy: Romantic Relationship Experiences Across the Life Course

Most relationships do not last forever; as individuals search for a long-term, in some cases lifelong commitment, they date, live with, and sometimes marry different partners. Overall, unions in the United States, defined to include both cohabitating and marital unions, are at their most unstable point in recent history. Using longitudinal data from the National Longitudinal Survey of Youth (NLSY) 1979, a nationally representative data collection of over 10,000 adults who were between 14 and 21 in 1979, scholars have found that by the age of 40, about 12 percent of the sample had never had a union, while 40 percent were still in their first marriage, and 2 percent were in their first cohabitation. Therefore, 46 percent of the sample by the age of 40 was in second, third, or even higher-order unions. Thus, over time, individuals cycle through relationships, experiencing divorces and the dissolution of cohabiting or dating relationships along the way.

Union instability may be even greater by the age of 40 for contemporary cohorts of young adults. Scholars have compared data from the NLSY 1979 cohort and the more recent 1997 cohort, a nationally representative sample of over 8,000 individuals who were ages 11 to 14 in 1997 and have been re-interviewed annually since. By age 24, 41 percent of the NLSY 1979 cohort had never had a union, while a similar 39 percent of the NLSY 1997 cohort had never had a union. Thirty-seven percent of the NLSY 79 cohort was in their first marriage, while only 20 percent of the NLSY 97 cohort was in their first marriage. In contrast, 6 percent of the NLSY 79 cohort was in their first cohabitation, but 12 percent of the NLSY 97 cohort was in their first cohabitation. Another change was that by age 24, only 5 percent of the NLSY 79 cohort was in a higher-order union, 60 percent of which were marital unions, whereas 9 percent of the NLSY 97 cohort was in a higher-order union, 86 percent of

which were cohabiting unions. One final note of change is that the proportion of individuals who were single after a union dissolution doubled between the two cohorts, from 11 percent in the NLSY 1979 cohort to 20 percent in the NLSY 97 cohort. Thus, even by age 24, it is apparent that changes in relationships, including unions, have increased both over time for these individuals, and across historic time as well. Some scholars, including Paul Amato and Andrew Cherlin, have called this cycling of monogamous relationships “serial monogamy.” Serial monogamy has come to partly define the baby boomer and subsequent cohorts’ relationship experiences.

The process of individual relationship development occurs and recurs across the life course and in historical context. Given the changing historical context of romantic relationships and their various forms at the beginning of the 21st century, it is difficult to predict what is in store for the development of romantic relationships. Although almost 95 percent of high school seniors in the 2006 Monitoring the Future study reported that they planned to marry someday, only about 36 percent agreed that “most people will have fuller and happier lives if they choose legal marriage rather than staying single, or just living with someone.” It is likely that as time goes by, relationships will become increasingly diverse, while simultaneously, individuals will experience increasing numbers of relationships that vary in their degree of commitment across their life course.

CHILD ABUSE AND NEGLECT

Young children's experiences with their caregivers can be the most influential of all human relationships. Children develop expectations regarding future relationships based on the quality of early interactions with their caregivers. When children experience warm and responsive caregiving, they are likely to believe that others are trustworthy and that relationships can be fulfilling. They also begin to view themselves as deserving of positive connections with others. When caregiving is harsh or unreliable, children may begin to expect that their needs will not be met by others and may begin to believe that positive relationships are unattainable. Because of the continuity between early experiences and subsequent relationship expectations, child maltreatment can exert a devastating impact on the quality of relationships across the life course. It is important to note that child maltreatment refers to all subtypes of child abuse and neglect, including physical abuse, sexual abuse, emotional abuse, and neglect.

This entry examines the processes associated with child maltreatment that hinder the attainment of positive human relationships. In particular, it explores the compounding effects of child maltreatment that can affect the quality of relationships from infancy to adulthood. Special attention is directed toward factors that promote adaptive functioning despite the adversity associated with maltreatment. Finally, implications for social policy and intervention will be addressed.

Definition and Epidemiology

The first official case of child maltreatment in the United States was documented in 1873. Since then,

controversy has existed over how to define child abuse and neglect. This debate has been largely political, leading to shifts over time regarding what acts are considered abusive or neglectful. For example, when funding allocation for social services is low, only the most severe cases of maltreatment are investigated. In addition, tension has existed between liberal and conservative views regarding the degree to which the government has the right to intervene in families, with the latter tending to be more broadly committed to the protection of parental rights to raise their children as they see fit. Moreover, there has been ongoing dispute over whether child maltreatment should be defined based on the actions of the perpetrator or on the effects on the child. Additionally, researchers debate over whether to consult public records or to interview children directly to ascertain that maltreatment has occurred. The lack of a clear definition for child maltreatment, or an agreed-upon standard for identifying an incident, can cause prevalence estimates to vary considerably.

Recent estimates from public records suggest that 12 out of every 1,000 children in the United States have been victims of child maltreatment. This estimate is most likely a gross underrepresentation, as it only reflects documented occurrences. Of the documented cases, it has been estimated that approximately 63 percent involve neglect, 17 percent involve physical abuse, 9 percent involve sexual abuse, and 7 percent involve emotional abuse. However, these estimates may also be misleading as research indicates that the vast majority of maltreated children experience more than one type of maltreatment.

Research has helped to elucidate the detrimental effects that various types of maltreatment can have on children. Findings suggest that the effects of child maltreatment on relationships can be particularly harmful if the maltreatment occurs during the first 5 years of life or is chronic in nature. Research also has indicated that the severity and type of maltreatment can have differential impacts on children depending on the child's developmental stage at the time of the maltreatment. More specifically, the severity of emotional abuse in infancy and toddlerhood, as well as physical abuse during the preschool period, are especially potent predictors of later acting out behaviors both in the context of familial and peer relationships. Acting

out behaviors may include physical aggression, bullying, or verbal hostility. Conversely, the severity of neglect during the preschool years is associated with depressed and withdrawn behavior such as social isolation, tearfulness, and thoughts of suicide.

Attachment With Caregiver

Young children learn about themselves and the world around them within the context of their relationships with caregivers, most importantly their parents. These early experiences provide a foundation for relationships with other individuals not only during childhood but across the life course. Beginning in infancy, children develop a way of relating to their caregivers known as attachment. Children who experience sensitivity and responsiveness in their early interactions are likely to develop a positive view of themselves and others and therefore are likely to form secure-attachment relationships with their caregivers. Securely attached children believe that their needs will be met and therefore will have the confidence to explore their environments. They are also likely to utilize their caregivers for support and comfort during times of distress and to learn to regulate their emotions appropriately. Consequently, securely attached children are likely to be able to appropriately identify and communicate their feelings to others and to experience positive social interactions.

In that a child's primary caregiver is the indicated perpetrator in more than 80 percent of cases of maltreatment, child abuse and neglect can profoundly disrupt the development of a secure-attachment relationship. Maltreating caregivers engender fear and uncertainty in young children through their lack of sensitivity and reliability. Consequently, maltreated children are likely to form insecure- or disorganized-attachment relationships with their caregivers. Research indicates that maltreated children are more likely than those who have not been maltreated to develop an avoidant-attachment relationship with their caregivers. They exhibit their avoidance by minimizing physical proximity, eye contact, and expression of their emotions in the presence of their caregivers. Because avoidant children expect rejection when in

need of comfort, they often fail to develop productive ways of expressing negative emotions, even as adults. Other children respond to their maltreating caregivers' unpredictability by expressing considerable dependency when interacting with their caregivers. This attachment pattern is known as anxious or ambivalent. These children put forth extreme efforts to seek closeness and reassurance from their caregivers but typically fail to derive true comfort from the relationship. Anxious or ambivalent children tend to become so preoccupied with the relationship that they neglect to explore the world around them. With fewer opportunities to apply positive social and emotional skills in relationships, they often have difficulty regulating their emotions and become fearful, sad, or angry. Finally, some maltreated children fail to develop an organized strategy of relating to their caregivers. These children have a disorganized-attachment relationship and tend to exhibit fear, an inability to regulate their emotions, or complete disengagement in the presence of their caregivers. Children with disorganized attachments exhibit the most troublesome outcomes of all. They are the most likely to demonstrate low self-esteem, poor school performance, and high levels of anxiety. Children who form insecure or disorganized attachments are unable to utilize a partnership with their caregivers to help them organize future behavior and patterns of relating to others.

Relationships in the Family

Maltreating homes are exemplified by disorganization, inconsistency, and chaos, particularly in the context of familial relationships. Physically abusive parents are typically aggressive toward multiple members of the family. Likewise, neglectful parents are likely to be inconsistent and cold in many of their familial relationships. In general, maltreating parents are less satisfied with their children and find parenting less enjoyable than do non-maltreating parents. These maladaptive patterns of relating can contribute to the collapse of social structure in the family system. Consequently, maltreating families typically lack clearly defined social roles in the home, causing maltreating parents to have unrealistic or age-inappropriate expectations for their young children. These

expectations often lead to role reversal in the parent–child relationship, with the child tending to his or her parent’s needs. Without support from their caregivers, maltreated children often fail to develop appropriate skills for relating to others. These difficulties can persist throughout the life course.

Peer Relationships

As childhood progresses and the school years commence, children begin spending more of their time in the company of individuals outside of the home, and peer relationships play an increasingly important role in social and emotional development. The experience of maltreatment may lead some children to develop aggressive or withdrawn behaviors that serve to protect them from physical or psychological harm with the caregiver but that also may create a barrier to forming positive relationships with peers. Researchers have found that maltreated children are more likely to be rejected by their peers than are children who have not experienced maltreatment. There is evidence to suggest that the increased use of physical and verbal aggression by maltreated children may be one of the mechanisms that contributes to them being more likely to be rejected by their peers. Based on their early experiences with their caregivers, maltreated children also tend to withdraw from, and even avoid, interactions with their age mates. These behaviors may also lead to peer rejection, which can make it more difficult for maltreated children to establish friendships. In some maltreated children, both aggressive and withdrawn behaviors are exhibited, and when present, such children demonstrate much lower social effectiveness. When maltreated children are able to establish friendships, they are often experienced as less caring and more marked by conflict.

Research also has shown that maltreated children are significantly more likely to be perpetrators and victims of bullying than are non-maltreated children. Children who have been physically and sexually abused are particularly likely to display bullying behaviors toward their peers. Additionally, greater severity and chronicity of maltreatment tends to be associated with more difficulties with peer relationships. This pattern suggests that the

more disrupted the early relationship between caregiver and child, the greater challenges maltreated children are likely to face in relationships with their peers.

Relationships With Teachers

Research has identified continuity between the quality of children’s attachment relationships with their caregivers and subsequent attachment with their teachers. Children who have experienced secure attachments with their caregivers are more likely to perceive their teachers as warm and supportive. This positive perception of teachers contributes to children being more motivated and having more confidence in the classroom. Children who have been maltreated and have developed an insecure or disorganized attachment with their caregivers are more likely to exhibit maladaptive patterns of relating to their teachers, as characterized by the child’s increased need for dependency, approval, and help-seeking behaviors. However, children who have been maltreated often exhibit patterns of relating that prevent them from deriving the support that they need from their teachers. Some physically abused children exhibit disruptive or aggressive behaviors that lead to disciplinary actions, minimizing the time spent in the classroom. Other maltreated children are more likely to withdraw while at school, causing their needs to be overlooked by their teachers. Without supportive relationships with their teachers, children who have been maltreated often lack the motivation to do well in school and to behave appropriately. Thus, it is not surprising that maltreated children are less successful at school than their non-maltreated classmates. Poor academic achievement can have dire implications across the life course, placing individuals at risk for unemployment and potential poverty.

Romantic Relationships

In addition to experiencing difficulties forming and maintaining positive relationships within the family and with peers and teachers, individuals who were maltreated as children often go on to experience disruptions in their romantic relationships. Individuals who experienced maltreatment early in

life are more likely to have insecure patterns of attachment with their romantic partners than adults who were not maltreated as children. Furthermore, researchers have found that childhood physical abuse is associated with violence and aggression in romantic relationships. Individuals maltreated as children are more likely to be both the perpetrator and the victim of violence in these close personal relationships.

Intergenerational Transmission

Having a history of maltreatment during childhood also heightens the risk for perpetuating maltreatment on future generations of children. The insecure- or disorganized-attachment patterns that maltreated individuals often experienced with their own caregivers may disrupt their view of how a healthy caregiver–child relationship operates. Individuals who were maltreated as children also are at increased risk for experiencing difficulties with self-regulation and moral development as adults, which may contribute to them becoming maltreating parents. The absence of being able to learn positive parenting behaviors from their own caregivers also can result in the perpetuation of maladaptive parenting. Research also has found that physically and sexually abused individuals are more likely to be young parents, to experience mental illness, and to live with a violent partner. These high-risk behaviors and experiences may place maltreated children at risk for becoming maltreating parents.

Disruptions in the early parent–child attachment relationship caused by child maltreatment can trickle down to negatively impact the individual's sense of self and their interpersonal relationships with their other family members, peers, teachers, romantic partners, and even their own children. Additionally, it is likely that these difficulties in close relationships influence and build on each other to contribute to continued problems throughout the life course. However, although child maltreatment contributes to increased risk for significant interpersonal difficulties, it is important to note that there is not a one-to-one correspondence between maltreatment and maladaptive relationships. Recent estimates suggest that approximately 70 percent of maltreated children do not

become abusive parents. Thus, the experience of child maltreatment does not doom an individual to follow a negative pathway.

Resilience

Some maltreated children display resilience, meaning that they go on to adapt positively to their surroundings and to avoid difficulties with interpersonal relationships despite early experiences of adversity. It is important to identify factors that promote resilience in the face of child maltreatment, as these issues may possess important implications for developing effective prevention and intervention programs. Research suggests that the way in which children view themselves is a significant contributor to resilience in maltreated children. More specifically, researchers have found that maltreated children who have high self-esteem and who feel in control of their actions are more likely to be resilient. Further, research has shown that adaptive behaviors at one developmental stage are not necessarily indicative of resilience at other developmental stages, nor does maladaptation at one stage of development necessitate difficulties at subsequent stages. Since maltreated children tend to experience difficulties in relationships at many life stages, it is important to identify resilience factors and effective interventions across developmental periods. In fact, research has shown that having a positive experience with even one caring adult such as a teacher can serve as a protective factor that diminishes the adverse consequences of child maltreatment. Experiences with supportive adults can help children recognize that not all relationships are hurtful.

Future Directions and Implications for Intervention and Public Policy

In the decades following its initial recognition within the medical community, research on the psychological consequences of child maltreatment has burgeoned. Researchers now know that the childhood maltreatment can exert a deleterious impact on functioning and on relationships across the life span. As research knowledge has become increasingly sophisticated, however, efforts to apply this knowledge to the formulation of social

policies on behalf of victims of maltreatment have been much slower to emerge. It is clear that simply stopping maltreatment once it has occurred is not sufficient to ameliorate its negative developmental consequences. Although researchers possess information on the effectiveness of various treatment approaches, most of this knowledge pertains to interventions directed at physical and sexual abuse. Efforts must be increased to develop and evaluate interventions for children who have experienced neglect and emotional abuse. In addition, even though empirically supported treatments are available, they are not consistently provided in settings that are most likely to treat low-income, maltreated children. It is critical that efforts be facilitated to export scientifically supported interventions into practice in therapeutic and school settings, as this will ensure that children most in need of these services can attain them.

Over the past several decades, attention has been increasingly directed toward understanding the neurobiological correlates and consequences of maltreatment. However, too few studies have examined psychological and neurobiological functioning in tandem. Animal models have provided evidence that early-occurring postnatal abuse and neglect can affect behavioral and neuroendocrine responsiveness, gene expression, brain structure and function, and neurochemical markers, as well as the development of processes that have been associated with the emergence of psychiatric disorders. Investigations that have been conducted with maltreated children have begun to reveal relations between the regulation of cortisol, a stress hormone that is activated in response to acute trauma, and psychopathology. Research conducted at multiple levels of analysis is increasingly important for informing policies and interventions on behalf of victims of child maltreatment.

Because there is continuity between the quality of early caregiving relationships and future relationship functioning, early intervention and prevention programs are essential for promoting positive representations of self and others in children's earliest relationships. Preventive interventions directed toward the amelioration of difficulties in the attachment relationships of maltreated children have been developed and have been found to be effective. It is imperative that such prevention efforts be more widely available

so that the suffering associated with child maltreatment can be assuaged.

CHILDREN'S PEER GROUPS

Peer groups are a ubiquitous phenomenon of childhood. As soon as, and probably before, children begin to walk, they take special interest in peers of

a similar age. In all cultures and ethnic groups, children spend considerable time with peers, and it is taken for granted that peer experiences foster development and psychosocial adjustment. This entry distinguishes different kinds of peer groups and their measurement and outlines strategies for studying their developmental influences.

Forms of Peer Groups

Peer groups come in many forms. A broad distinction is whether groups are culturally and institutionally assigned or formed by children themselves. The term *peer group* is often used to describe assigned groups, that is, collections of children who are brought together in institutionalized settings. Examples of assigned groups are classrooms, work groups, teams, or clubs that are organized by adults.

Assigned groups are very different from natural self-selected groups that children voluntarily and spontaneously create by themselves. Such groups exist as *social crowds*, *friendship cliques*, or *social networks*. These groups are comprised of children who belong to specific social categories, share emotional bonds, or interact frequently with one another. Their labels highlight specific characteristics of the different groups in terms of cohesiveness, interpersonal closeness, and interconnectedness of interaction patterns.

Self-selected groups sometimes refer to *social categories*, defined by similarities among members in terms of personal characteristics, reputational attributes, or aspirations. Examples are social crowds of “brains” or “jocks” or groups of children who are “rejected” or “neglected” in a setting. Members of such groups do not necessarily interact with one other and sometimes do not even know each other.

In contrast, *affiliation groups* consist of peers who have chosen each other among available candidates, interact on a regular basis, and often share emotional bonds. Examples are groups of friends or social networks of peers who undertake joint activities. These groups differ from work groups, gangs, or clubs because there is usually no formal goal for the group other than to feel close and to share experiences. The groups tend to be overlapping and fluid; members are free to leave, and new

candidates can join at any time. Because membership is determined by children themselves, researchers are skeptical about the extent to which traditional findings on experimentally or institutionally assigned groups are applicable.

Measurement

Measurement strategies in research are closely tied to the nature of the different groups. When groups are culturally or institutionally assigned, there is no problem with identifying groups; the members can be listed by the adults who assigned them, and the groups are distinct and stable. Measures capture how such groups develop social structures and group norms, how they differ from other groups, and how members interact with one another.

Identification of Natural Groups

When natural groups are of interest, members need to be identified. Children usually are the source of this information. One strand of research focuses on social categories, following Jacob Moreno's Sociometric Method and Kurt Lewin's Field Theory. Sociometric groups of popular, rejected, neglected, or controversial children are identified from nominations of “most-liked” and “least-liked” peers, usually by transforming nominations into scales of social preference and social impact. Social crowds are defined as prototypical groups of, for example, “nerds,” “jocks,” or “burnouts,” and identified via peer nominations or self-referrals.

In order to identify affiliation groups, actual ties between individuals need to be captured. Following Moreno's Sociometry, the two main approaches focus on friendship cliques or on networks of children who regularly interact with one another. Friendship approaches assume that interpersonal closeness is the most important characteristic; children are asked to nominate their friends in a classroom or grade. Reciprocity of nominations is seen as the defining feature, often supplemented by ratings of relationship quality. Clusters of friends are identified as cliques, typically, using graph-theoretical strategies: Groups need to be larger than dyads, friends of a friend are also considered friends, every member of a group can be reached

by every other member at least through an indirect path, friendships not embedded in groups are excluded, and structures are accepted as groups if they do not fall apart when one tie is removed.

Social network approaches assume that social interactions are a group's defining characteristic; close relationships may or may not emerge from interactions. Because of skepticism about children's self-reports (e.g., self-enhancement biases), observational strategies are preferred. Children are either directly observed, or child participant observers nominate the peers whom they frequently see interacting in groups (sociocognitive mapping). Groups are identified via cluster analyses, correlational and factor analytic techniques, or comparisons of conditional membership probabilities (if X has a group, is Y a member?) with unconditional probabilities. Often, co-occurrence patterns are inspected to distinguish central groups (and central individuals within groups) from less central groups (and peripheral members).

Group Profiles

Once group members are identified, the second challenge is to capture the features of groups that influence development. Traditionally, attention has focused on structural aspects like size, cohesiveness, within-group similarity, or gender differences. However, structural properties say little about groups' psychologically active features. As indices of groups' psychological characteristics, studies have used profile scores of key variables in the form of member averages (e.g., of classroom behavior). These scores have interindividual variability when they are individually created for each member. Thus, children's experiences are assumed to differ even within the same group (e.g., a girl in a group of boys is in a group of the opposite gender, while each boy is in a mixed-sex group). Profile scores make it possible to examine group characteristics as antecedents of individual members' developmental change over time.

Influence Processes in Natural Peer Groups

The most challenging questions for peer research concern the functions of peer groups in shaping development. Children who are liked by peers,

who belong to well-adjusted crowds, or who have high-quality friendship cliques or interaction networks, all tend to do better socially and academically. The question is whether this is because peers influence adjustment because children who do well tend to affiliate with other highly functioning peers, or because good peer relationships and good functioning are both caused by a common third variable (e.g., quality parenting). Empirical data support all three explanations.

Robert Hinde has argued that children's peer experiences need to be distinguished according to the levels of complexity at which they are constituted; influence processes may differ by level. Individuals bring to peer interactions their personal dispositions, social orientations, and skills. These characteristics are played out in interactions with peers, who themselves bring their own characteristics. Many interactions are embedded in long-term relationships that shape interactions. Finally, relationships are embedded in social groups that are defined by relationships and interactions among members, by emergent properties such as group norms or cultural conventions, and by various forms of organization and structure, in the groups as well as in the larger setting (e.g., social hierarchies, levels of cohesiveness).

Researchers have pointed out that failure to distinguish these levels can lead to confounding of different kinds of social influences. Children who are rejected by their classmates can nevertheless have friendships and be central members of peer groups; children's friendship cliques do not necessarily include the same peers or cover the same activities as their interaction networks; members of the same social crowd may or may not have relationships or social interactions with one another. Hence, even though indicators of peer experience from different levels are generally associated with individual functioning, it is likely that the processes of social influence underlying these connections differ at the different levels.

Group Selection

Researchers studying the effects of peer groups sometimes neglect processes of selection. Natural groups exist only because children have chosen each other. Most models, including social-learning-based "shopping" models, Social Comparison

Theory, and close-relationship models, assume that groups form based on similarity. This has also been called *homophily*, *mesh*, *assortativeness*, or *synchrony*. The term synchrony is noteworthy because it highlights that selection processes continue after a group is formed; over time, children who do not remain in synchrony with their group drop out.

Studies of natural groups consistently show homogeneity on a variety of attributes (e.g., orientation to school, academic aspirations, tendencies for school drop-out, prosocial and problem behavior). Although similarity is often seen as the result of member influences, this is not necessarily so; groups are formed based on similarity and, often, peers stay with a group only as long as they remain in synchrony. This is different from experimentally assigned groups; when members are randomly assigned, member convergence necessarily implies influence through group interactions.

Social Influence in Natural Groups

Group influences are considered *socialization processes*. The traditional understanding of socialization is that influences are unidirectional, from a socialization agent to a child, and that they produce conformity. In natural peer groups, however, the socialization agents are other children, similarity already exists in many features when groups are formed, and the groups are fluid and overlapping. Such groups may not necessarily increase conformity. Theoretically, it seems hard to reconcile beliefs that intimate relationships support individual development with expectations that they act as a social mold that enforces group conformity. Instead, peer groups may foster autonomy and self-determination and may allow children to enjoy activities that they would not enjoy (as much) by themselves.

New strategies to examine peer socialization focus on changes within children. Because natural groups are self-selected, developmental influences are examined over and above initial member similarity. In friendship groups, changes in children have been found to be related to the make-up of their groups in terms of onset of deviant behaviors, in terms of academic aspirations, as well as attitudes and behavior. In interaction networks, similar patterns suggest that peer groups can lead

children to become more different from one another (i.e., the so-called Matthew Effect: Children with well-adjusted peers tend to improve over time, whereas children with less-adjusted peers tend to decline). Overall, influences of actual peer groups on changes in children, when members are independently identified and measured, appear to be smaller than concurrent correlations would suggest. Some researchers have become skeptical about whether peer group effects are larger than influences from parents or teachers. Only in specific subgroups of highly gifted, at-risk, socially secluded, or problematic children are there indications that influences may be substantially larger.

Gender Differences

Gender differences in peer groups are manifold; because children's groups tend to consist of same-sex peers, differences in group averages parallel individual gender differences. For example, on average, boys' groups seem less well-adjusted in school. However, there is much variation within each gender, and this variation often is larger than differences between genders. In addition, girls' groups are often smaller and more intimate, whereas boys' groups are more activity-based and sometimes less stable over time. On the one hand, this paints a positive picture of girls' peer relationships. However, increased intimacy comes at a cost when peer groups break up over school transitions or parental relocation. For example, girls show a marked drop in self-esteem when they enter high school, and this may be related to losses of intimate relationships and to struggles with peer group (re)integration.

At the same time, the exact nature of gender differences is not clear. Despite differences in mean levels of many variables, some authors suggest that not all gender-specific interactions magnify gender differences. It is possible that the core processes of peer group selection and socialization operate in a similar manner for boys and girls. Thus, even though girls select mainly girls (and boys select boys) as members of their groups, both do so according to their similarity with available candidates. Likewise, boys' and girls' peer groups influence their members toward gender-typical behavior, but the mechanisms and magnitude of socialization influences may nevertheless be quite similar.

For example, some studies have shown that, although girls are socialized to be more engaged in school than boys, peer groups of both genders shape their members' engagement through attention and reinforcement in daily interactions in the classroom.

CLOSENESS

Interpersonal closeness covers a multitude of relationship circumstances. It may be physical closeness, as in a packed subway car where people stand cheek by jowl to each other, with their sense of personal space being violated. People may be close in the sense of kinship or close in geographical space or in psychological warmth and supportiveness. In

organizations or communities, people may be close in the sense that few steps or links are required to communicate with each other. Finally, people may be close in the sense of having an impact on each other's lives. Traditionally, these effects are considered positive, involving support in practical and emotional ways, but the impact may be negative if closeness is associated with conflict, harm, or betrayal. The focus of this entry is on interpersonal closeness in the last sense—of the ways in which people have an impact on each other's everyday lives and the personal feelings associated with such closeness. This entry examines the three major traditions of conceptualizing closeness—from an interpersonal impact framework developed by Ellen Berscheid and her associates, from a personal sense of closeness developed by Arthur Aron and his colleagues, and from a layperson's intuitive sense of closeness.

Closeness Analyzed in Terms of Personal Impact

Interpersonal closeness has three distinct and important characteristics: First, it is a feeling of positive connectedness to one or more other persons. Second, it is an attitude embodying the same feelings of closeness and extending over a significant time period. And third, closeness may refer to the behavioral patterns that engender closeness. In this case, closeness presupposes the ability to interact regularly either face-to-face or via electronic means. Berscheid and her colleagues took the idea that when people are close they tend to have an impact on each other because they are interdependent—what person A does almost of necessity has an impact on what person B experiences and is likely to do and vice versa. Berscheid and colleagues asked the question, How does one best get at this kind of behavioral impact on feelings of closeness? They came up with three answers. They asked about the *frequency* of doing things together, the *diversity* or number of different things done, and the judgment of the *strength of impact*. Although each of these may affect felt closeness, they are not the same thing, and assessing each dimension separately seemed an important step to take. Berscheid and her colleagues named the inventory the Relationship Closeness

Inventory (RCI). Their research, in several samples, established that diversity and frequency were somewhat more strongly correlated with each other than with judged strength of impact and that both diversity and strength were modestly predictive of enduring relationships among romantic couples. By combining all three aspects of measured closeness into a single index, researchers have been able to achieve a substantial predictiveness of relationship endurance among both women and men. The RCI is one of the standard instruments used in the field by researchers interested in assessing degree of closeness and its implications.

The Personal Interconnectedness View of Closeness

Not long after the work on the RCI was completed, Arthur and Elaine Aron proposed that the RCI could be supplemented by a novel but simple measure of the degree to which two (or more) persons feel themselves to be included in each other's worlds or have a sense of being interconnected with each other. A series of seven sets of two circles (or triangles) is presented to members of a couple, and each selects the pair that corresponds to their degree of felt inclusion in each other's worlds. Circles that are merely touching but not overlapping at all represent acquaintances. Those in which the circles have substantial degrees of overlap would be indicative of including each other in one's worlds and, hence, of being especially close. Total overlap of circles would indicate a complete absorption of self and other into a oneness. The Arons gave the scale the name pictorial Inclusion of Other in the Self Scale (IOS). In an ingenious set of seven studies, they established that the IOS brought a distinct and important contribution to the measurement and predictive power of closeness measures. One important conclusion of their several studies was that it is necessary to distinguish the concepts of felt or subjective closeness from the concept of behavioral closeness as measured by the RCI. Even though the RCI was initially developed by having participants select their closest relationships, it is not primarily a measure of felt closeness. The IOS relates both to the subjective sense

of closeness as well as to the behavioral sense of closeness assessed by the RCI. The IOS was a better predictor of a 3-month relationship stability than the RCI, but they both contributed strongly to the felt distress a person would have if the relationship were to break up. An interesting gender difference came to light in these studies. For men, the longer they are together with their wives, the greater their closeness—both as measured by the IOS and the strength component of the RCI—but not for women. This finding fits with data suggesting that women form friendship and romantic bonds more quickly than men, but no firm interpretation has been provided.

In a study of the personal meaning of IOS responses, participants spontaneously mentioned feelings of "connectedness" as the primary theme. In ratings of the meaning given to the IOS, "union" and "closeness" were the most strongly endorsed.

The Lay Sense of Closeness

Much of the important and informative research on this topic has proceeded from the position that people know what they mean by closeness and can be trusted to give informative and reliable reports on their felt closeness to the people in their worlds. In the Arons' studies, the lay sense of closeness was related about equally both to the IOS and to the RCI strength measures. It also had a modestly positive relationship both to friendship and romantic relationship longevity (among men).

An especially useful application on this position has been incorporated into several uses of the Rochester Interaction Record (RIR), in which people report on qualities of their personal interactions over periods of 1 to 2 weeks. Because of its ability to get at the fine-grain detail of daily interactions and to give insights into factors that are influential in the development and the processes of personal relationships, the RIR has become a widely used procedure. In the context of these studies, one takes each interaction (of any significant time period) that one has had through the day and rates the degree to which it had several characteristics such as closeness, excitement, satisfaction, conflict, attraction to the other, enjoyment, and so on.

Implications of Feeling or Being Close to Others for That Relationship

Intimacy and Closeness

To be close is, potentially, to be intimate in the sense that partners have shared personal information, know secrets about each other, and could hurt each other with the information held. There are two contexts in which closeness does not always involve intimacy. Within families, children and relatives tend to have spheres of information that are treated as not available for sharing, as it is none of the other's business. It is one of the marks of adolescence that, at some point, sons and daughters will stop sharing everything that they think and do with their parents. Likewise, parents often keep certain aspects of family and adult life hidden from their children. For some families, the hidden areas involved sexuality and physical intimacy; for others, family finances; and for others, the "black sheep" in the family tree, who, if known, would bring shame on the family. The discovery of some of these secrets in early adulthood is a common theme of coming of age novels or autobiographical works.

The Dark Side of Closeness

When one's partner or a family member tries to get too close so that their questions, comments, and even their physical presence can seem intrusive, one kind of "dark" closeness exists. Sensitivity to the possibilities of intrusive closeness is a characteristic of attachment avoidance, but real world cases exist in which the partner lacks a sense of appropriate boundaries and violates his or her partner's world. These violations are harmful to relationship satisfaction and stability.

The other context where closeness does not entail intimacy occurs when personal relationships are embedded in broader business or political organizations. In these circumstances, personal information is potentially a basis of personal power, and there is an incentive for even very close friends to be guarded in what they share. They cannot prevent the observation of personal information that arises from everyday interaction, but they may choose to remember that anything said, even in privacy, can come back to haunt the

speaker. A relevant maxim is that friends come and go—enemies accumulate.

In these broader contexts, closeness sometimes has a tactical use. When Mario Puzo's *Godfather* character says, "Keep your friends close and your enemies closer," he explicitly states the tactical use of closeness as a form of social control. As historian Doris Kerns has shown, Lincoln was a master of the tactical use of closeness when he placed his many rivals for the presidency in his cabinet, where he could watch their political moves closely.

Closeness and Marital Quality

The sense of physical and emotional closeness is typically related to the partner's mutual marital happiness and satisfaction, but a few interesting variations have been found. In examining the role of two personality traits—attachment security—insecurity and neuroticism—in marital quality, researchers found that couples agreed highly in their RIR ratings of closeness and that women's rating were more sensitive to personality variations and the effects of daily stressors. In this large study of couples, men felt close whether their attachment style was secure or not and whether neurotic or not. In contrast, women with either high degrees of attachment insecurity or neuroticism felt less close to their partners and had lower marital satisfaction.

Cultural Variations in the Forms of Closeness

The acceptable and typical forms of physical closeness to one's children vary by cultural heritage. Examples include beliefs about the benefits and limitations of certain practices regarding holding a child who cries, sleeping with one's children, and nudity among children. An interesting study of these issues has been conducted by an interdisciplinary team led by Fred Rothbaum at Tufts University. Conducting detailed interviews with 20 fathers and mothers each from European-American and Chinese-immigrant-American origin, they found that European Americans sleep in the same room with a child much less often than Chinese-immigrant parents and that to European Americans, nudity at home was acceptable but not to Chinese immigrants. Physical closeness clearly

had different psychological implications as a function of culture. The Chinese immigrant Americans placed an emphasis on harmony within the family; physical closeness fostered inhibition of emotional expression, adherence to correct values, and the acceptance of hierarchy within the family. In contrast, the European-American families emphasized independence and a romantic view of the family. They saw their practices with respect to physical closeness as fostering the distinctiveness and independence of their children, the open expression of emotions, and parental intimacy, pleasure, and exclusiveness.

Children's Relations to Their Grandparents

There is great variation in how often grandchildren get to be with their grandparents. Partly, this is a function of the significant residential mobility variations by geographical regions, such as the greater residential stability of the Midwestern heartland compared with either coast. A second factor that contributes to variations is a function of the relatively high rates of divorce, remarriage, and single-parent families. In a large study in an English village with significant residential stability, weekly or more frequent contact with grandparents was the norm. Family composition (living with natural parents, with one biological and one step parent, or in a single family) made little difference in contact, except for the grandparents related to the parent no longer living with the children. One interesting finding of this study was that the child's felt closeness to the grandparents was almost universally positively related to behavioral and mental health of the children. Children who felt close to their grandparents were less likely to get into trouble (e.g., antisocial behaviors) and less likely to be anxious, be withdrawn, or have psychophysiological symptoms. The sole exception was that closeness to a paternal grandfather in cases where the father was no longer living with the child was positively associated with antisocial behaviors. These cases seemed to be marked by ongoing conflict between the children's parents that spilled over into the child-grandparent relationship. Otherwise, grandparental support and closeness had largely positive implications for the grandchildren's development.

Brotherly Closeness

Kory Floyd conducted a series of studies of issues of brotherly love. In a sample of 59 brothers ranging in ages from the teen years through the upper 20s, he found that both Zick Rubin's liking and loving scales were correlated with behavioral closeness (RCI total score). Brotherly relationships were higher than other male-male relationships in all three dimensions—liking, loving, and closeness. Each of these three aspects of emotional and behavioral closeness had somewhat different predictors. A sense of interdependence was the only significant predictor of RCI closeness; whereas love was predicted by the depth of the relationship and degree of commitment, liking was predicted by the breadth of the relationship and degree of commitment. Brothers reported being less behaviorally close to each other with age. This probably reflects their moving into commitment romantic relationships or moving away for school and jobs. These changes have been shown to reduce daily contact and thus to reduce both the frequency and diversity of the RCI closeness dimensions.

Closeness and Conversational Qualities

How does felt closeness influence the conduct of conversations among friends, acquaintances, and strangers? Gail Hornstein did an interesting study of naturally occurring telephone conversations among women. She secured permission to audiotape all conversations by 10 women and did so over a 2-to-4-week period. She selected 20 conversations each with friends, acquaintances, and strangers and subjected these both to content analysis and to structural analysis. Friends, in comparison to both acquaintances and strangers, covered more topics, were more responsive to each other by asking more questions and engaging in more supportive minimal responses while the partner was talking, and used more complex forms of closings. Thus the emotional closer the dyads were, the more the form and the content of the conversations differed from less close dyads.

Online Communication and Closeness

Insight into how online communication among youth would be related (a) to the development of new relationships and (b) to the maintenance of

existing friendships has been provided by a Dutch team, Patti Valkenburg and Jochen Peter. In a sample of 794 Dutch youth (ages 10–16), 84 percent (665) used the Internet for instant message or chat. Most (88 percent) of these youths communicated via the Internet with their preexisting, off-line friends, but many (24 percent) also explored chat rooms or social network services for new acquaintances. For those who communicated with preexisting friends, the more online communication, the greater the felt closeness to friends and this relationship was mediated by the felt depth of their Internet communications. In these cases, the Internet seemed to facilitate the sharing of experiences and feelings and the sense of really knowing the other. For participants who were very lonely, the Internet was not effective in the development of closeness, either with friends or newcomers.

CODING SYSTEMS FOR OBSERVING INTERACTIONS

People have been interested in and making observations and commentary about relationships since humankind developed the capacity for language. The development of scientifically based and empirically sound measures that allow for the systematic study of dyadic, triadic, or larger group dynamics has a much shorter history, however. Observational coding systems began to be developed in the late 1960s. Observational coding refers to efforts to describe, either live or more commonly from videotaped interactions, observable responses of individuals. What better way to understand how couples, families, friends, or siblings function and get along than to observe them directly? Direct observations have high face validity and are thought to be less vulnerable to confounding influences than self-report questionnaires. This entry provides an overview of how observational coding systems contribute to the scientific study of human relationships and describes some of the methodological considerations in conducting an observational study.

Observational research provides data that cannot be easily obtained from other sources. How people behave may be quite different from how they perceive themselves, and only direct observation can

capture this distinction. As outside observers of the marital or family system, properly trained coders add unique and independent information from that provided by the family members themselves. Observational measures are not necessarily more valid than other approaches, however, and they are not necessarily more objective than other research tools. As with all research measures, choices are made in the development and selection of coding systems, and these choices are informed by the theoretical model or possible biases of the investigator.

What Can Observational Measures Tell Researchers?

The direct observation of behavior as a means of understanding relationships is intuitively appealing. If one wants to know how well a relationship is working, just watch it and see what happens! Arguably, the greatest advantage of observational methods over self-report measures is that they are able to capture behaviors or relationship dynamics that most people cannot accurately describe or do not have adequate awareness of. Examples include rates of behavior, behaviors that are fleeting or subtle such as affective expression, or behavior patterns that are socially undesirable and therefore subject to distortion or denial. Measures of base rates allow researchers to ask questions about how much a certain behavior is exhibited in an interaction. Base rates refer to the frequency with which a behavior occurs within a specified time frame. For example, a researcher might want to know whether distressed couples express more critical comments over the course of a problem discussion than happy couples do or whether the rate of negative comments per minute is higher. Subtle changes in facial expression can result in very different emotional experiences, and the measurement of the mean duration and intensity of positive and negative facial expressions have been linked to behavioral changes in the course of an interaction.

Relationship behaviors that are socially undesirable or complex and difficult to have awareness of as a participant also lend themselves well to observational methods. For example, observational research has identified several patterns of interaction that place couples at risk for divorce or

distress. One of these is called *demand-withdraw*, meaning that one partner's request for change, support, or attention is likely to be followed by avoidance or withdrawal from the other partner. In addition, the probability of hostility or negativity from one partner being followed by similar behavior from the other partner is significantly higher in distressed than in nondistressed couples. Contempt, defensiveness, and withdrawal have been shown in observational studies to be highly predictive of marital instability. It would be very difficult for individuals to report on these types of constructs on themselves with any objectivity. Even for behaviors less subject to a social desirability bias, inadequate self-awareness may make accurate reporting by the participants difficult. For example, self-report is difficult when assessing the frequency of behaviors such as validating head nods, supportive tones, or eye contact.

Observational methodology may be particularly well suited to the study of families, as it allows for examination of relationship dynamics that go beyond the individual level of analysis and even beyond the dyadic level (e.g., parent-child, marital). An important goal of studies of family functioning is to describe mechanisms linking parenting and child development and to investigate the reciprocal and transactional ways in which these effects take place. For example, harsh and inconsistent parenting observed in the lab setting has been found to be associated with and longitudinally predictive of children's adjustment difficulties, including delinquency, drug and alcohol use, and depression. The theory of coercive family processes proposes that antisocial child behavior results from a complex behavioral pattern where parents and children engage in increasingly coercive behavior to "win" compliance struggles. Observational studies have shown that in these struggles, children tend to match their antisocial behavior to the "payoffs" offered by parents, usually in the form of the parent backing down and removing the demand for compliance. Children thus come to learn to avoid compliance by escalating their aversive behavior. Much of the foundation for this now well-accepted theoretical model comes from observational coding of parent-child interactions.

Observational methods are not necessarily superior to other means of collecting information about relationships, but rather, they complement other

approaches such as self-report questionnaires. Self-report measures tend to be most effective at capturing internal experiences such as thoughts and feelings. Observational methods, on the other hand, are often used to illuminate couple or family processes that might explain the development or maintenance of self-reported problems or issues. For example, self-report measures are likely to be most useful in assessing internal states such as level of marital distress or depression, while observations of couple interaction patterns can help researchers understand how depressed mood affects relationship dynamics. Self-report measures also can identify areas of concern such as child externalizing or internalizing problems, while observations of family interactions can help identify important dimensions of parenting (e.g., coercion) or whole family functioning (e.g., conflict, cross-generational alliances, triangulation) that appear to sustain child maladaptation over time. In addition, observational coding can identify discrepancies between self-report data and behavior that can be enlightening. For example, a depressed parent may describe his or her child as irritable and oppositional, but that child may appear cheerful and cooperative in the observational setting when interacting with the other parent, despite appearing subdued or hostile with the depressed parent. These types of discrepancies may help to disentangle some of the environmental factors that affect child behavior.

Level of Inference

The challenge of observational coding is to find a way to reliably rate, describe, and categorize ongoing streams of interaction. The goal is to figure out how to carve up a seamless flow of interaction between two or more parties into meaningful units that can be reliably and validly coded, without losing the integrity and richness of the entire interaction.

Coding systems differ in the level of analysis at which the coding takes place and tend to vary according to the relationship processes that are of interest to the investigator. Some concepts require a higher level of inference than others, while other constructs may be more concrete, focusing on specific behaviors and their sequential ordering.

Coding systems traditionally have been categorized as either macroanalytic or microanalytic, though mid-level coding systems have also begun to emerge. At a very broad level, macroanalytic systems can be defined as involving larger coding units and more inference is required, and therefore, there is more heterogeneity in the coded behavior. Microanalytic coding systems, on the other hand, involve smaller coding units, more discrete behaviors, and hence less data reduction. Microanalytic systems therefore are often considered less vulnerable to bias.

Macroanalytic ratings are often thought to be most valuable for studying behaviors and interaction sequences that are expected to be consistent across time and setting, as well as behaviors that are thought to be meaningful but less frequent. An advantage of macroanalytic codes is that they are able to take into account the larger context in which a behavior occurs, and they also are able to take into consideration the interdependent nature of relationship behaviors. In macroanalytic coding, behaviors are usually rated once for an entire interaction period. For example, a couple might be coded for the degree of negative escalation that occurs over the course of the interaction, or a family might be coded for degree of cohesiveness.

Microanalytic ratings are commonly used to study behavioral contingencies that occur during an interaction. Microanalytic codes allow for very fine-grained analysis of interaction patterns. For example, it might be interesting to know the probability of a particular behavior, such as a blaming statement, being followed by a neutral as opposed to a defensive statement made by the partner. Microanalytic coding typically involves recording the presence or absence of discrete behaviors during brief time intervals (e.g., 6–10 seconds). In a microanalytic system, the largest unit of behavior to be coded might be a sentence and the smallest unit might be a grunt or gesture. Some marital coding systems use a *floor switch* as a unit of coding, which includes a statement made by one partner and the following statement or action of the partner. Other systems code *thought units*, which refer to a verbal response, of any length, that focuses on a particular theme or content area. A disadvantage of microanalytic systems is their expense. It can take 2 hours to code a 10-minute interaction and several months to get coders trained to desired

reliability standards. The time and complexity of microanalytic coding increases notably as the number of participants increases. This may be why microanalytic systems are less common in family research than they are in couples research.

Mid-level coding systems, sometimes referred to as mesoanalytic systems, attempt to capitalize on the advantages of microanalytic and macroanalytic approaches. The time unit for coding is usually every minute or 2 (rather than every 10–15 seconds or once per 10-minute interaction). Event-based coding systems would probably be best categorized as a mid-level coding system. In this case, coding is not based on time units, but rather, certain identified events are the used to segment the interaction. For example, one might code parent-child interactions and their antecedents and consequences that fall into specific categories such as control or teaching events.

Is Observational Coding Ecologically Valid?

A vexing conceptual issue for observational research is whether the recorded data generalize to the real world. For example, the representativeness of observational coding may be affected by participant reactivity or the setting in which the interaction occurs. At a global level, videotaped interactions may be awkward, perhaps because the participants are self-conscious. More specifically, the generalizability of interactions may be reduced if the participants try to create a more favorable impression. Studies suggest, however, that it is hard for family members to “fake good” and that this is particularly true for more disturbed families. Thus, it is possible to observe negative relationship dynamics even when family members are reluctant to display them. Families or couples who do not know how to resolve problems in a productive or respectful manner, for example, are not able to produce smooth, well-regulated interactions just by trying to do so. Settings also may affect the representativeness of the interaction, and home observations tend to elicit more negative behavior than laboratory-based interactions. Less is known, however, about the differential ability of these two data collection sites to predict outcomes over time. Regardless of the setting, however, it is not unreasonable to ask

whether the observed behavior is necessarily representative of what happens in more naturally occurring contexts. Although it is important not to confuse the occurrence of a behavior with its representativeness, the general consensus appears to be that observational methodologies make an important contribution to the study of human relationships by uncovering processes that would otherwise be potentially less well examined.

COGNITIVE BEHAVIORAL COUPLE THERAPY

Whereas most couples enter into marriage or similar committed, romantic relationships with the full expectation that they will live their lives together in a happy and rewarding manner, the divorce rate in the United States and many

Western countries continues to be alarmingly high; in the United States it hovers around 50 percent. As a result, mental health practitioners have focused energy on ways to alleviate relationship distress. Many approaches for assisting distressed couples have been developed, yet very few have been evaluated to demonstrate that they actually help couples. This entry describes one of the scientifically based approaches referred to as Cognitive Behavioral Couple Therapy (CBCT) and includes a description of its historical roots, overall intervention strategies, and its effectiveness.

Historical Roots

As the title implies, CBCT places strong emphasis on how partners in a relationship behave, along with their cognitions or thoughts about their own and the other person's behavior. It has its historical roots in Social Learning Theory, which emphasizes that people learn to behave in a social or interpersonal environment such as from parents and family, friends, and society at large. For example, most children observe their parents demonstrate how to treat (or not treat) a partner. Likewise, individuals are rewarded or reinforced for behaving in certain ways in romantic relationships, such as receiving a smile from a partner after taking care of chores. Similarly, a romantic partner might be punished or ignored for forgetting the other person's birthday. In essence, people learn how to behave in both adaptive and maladaptive ways in committed relationships.

In addition, individuals give meaning to their own behavior and their partner's behavior within intimate relationships. For example, forgetting a partner's birthday might be devastating if it is interpreted to mean, "You don't love me." Some people's interpretations of relationship events seem reasonable and adaptive, yet others think about relationship events in distorted or maladaptive ways. Thus, an individual who concludes, "You purposely fell off the high ladder because you don't want to go to the party with me," probably is interpreting the partner's behavior in a distorted way.

CBCT was developed in the 1960s based on these scientific principles of relationship functioning, emphasizing each partner's behavior toward the other, along with thoughts or cognitions about

those behaviors. In addition, strong emphasis is placed on emotions, recognizing that a major source of satisfaction and distress is how partners feel about each other emotionally.

Treatment Strategies

Based upon the above principles, CBCT has evolved as a couple therapy approach that targets partners' behaviors, cognitions, and emotions with a primary emphasis on the current relationship, in contrast to other therapies that place an emphasis on the partners' childhood or early development. When targeting behaviors, CBCT often includes a focus on teaching couples how to communicate effectively because communication is one of the strongest predictors of relationship satisfaction long term. In addition, behavioral interventions include an emphasis on noncommunication behavior such as how to demonstrate small, caring, loving acts toward the other person, along with minimizing destructive behavior such as criticizing the other partner. CBCT also emphasizes that couples must incorporate these new ways of relating outside of the therapy session; therefore, couples frequently are asked to practice what they have learned during the session in their day-to-day lives.

From a cognitive perspective, a number of interventions are applied as necessary. For example, one partner might make distorted explanations for the other person's behavior, such as in the instance of falling off a ladder described earlier. In this circumstance, a therapist would help the individual evaluate whether this explanation is likely and whether other explanations are more plausible. Similarly, one partner might have extreme standards for what a relationship should be like, such as, "You should want to spend every waking moment with me." In this instance, the therapist might help the individual develop a more moderate and attainable standard for how to behave in relationships.

With regard to emotions, the therapist might need to address emotional responses at either end of a continuum, from (a) assisting partners who are restricted in their experience or expression of emotions, to (b) helping partners who have difficulty controlling excessive emotional responses.

Helping individuals who are more restricted learn to express emotions is important not only because it assists communication but also because appropriate expression of emotion is a major strategy for increasing intimacy. Helping individuals who have excessive emotional reactions is critical because strong outbursts of anger or other forms of distress frequently alienate the other partner who likely will either withdraw or retaliate with similar strong negative emotional reactions.

Effectiveness and Application to Other Populations

Well over 2 dozen scientific investigations in several different Western societies demonstrate the effectiveness of CBCT for distressed couples. Approximately 50 percent of initially distressed couples in these studies are satisfied with their relationship after receiving CBCT, and another 10 to 20 percent demonstrate some improvement. It is important to note that other approaches to couple therapy such as emotionally focused couple therapy, insight-oriented couple therapy, and an approach similar to CBCT called Integrative Behavioral Couple Therapy also demonstrate similar effectiveness and response rates. The intervention strategies used in CBCT also have been adapted for couples in other contexts with promising findings, including relationship education for nondistressed couples and couple-based interventions in which one partner is experiencing significant individual psychological difficulties or health complications.

COGNITIVE PROCESSES IN RELATIONSHIPS

How people think about themselves, their partners, and their relationships has a major influence on how they approach other people, how they feel about their relationship, and how they act toward their partners. There are a variety of methods and constructs that are included under the umbrella term *relationship cognition*. Mark Baldwin introduced the concept of *relational schemas* as a framework for understanding the cognitions people have about relationships. According to this perspective, relationship knowledge consists of a model of the self (self-schema, or how the self is experienced in a specific interpersonal situation), a model of the other person (partner schema, or how the other person is experienced in that interpersonal situation), and interpersonal scripts for expected patterns of interaction between the self and the other person. This perspective—that people develop cognitions representing regularities in patterns of interpersonal relatedness—may help to understand, organize, and integrate the various types of relationship cognitions that have been studied by relationship scientists. This entry provides background on relationship cognitions and summarizes research linking these cognitions to relationship functioning, particularly in terms of the well-being and stability of romantic relationships.

Attribution Processes

One cognitive process that has been shown to be important for relationship satisfaction and stability is the explanations or attributions that people make for events that occur in their relationship. People are particularly motivated to make attributions for unexpected or novel experiences, negative experiences, and experiences that are personally relevant. For example, consider the situation in which a partner does something negative and unexpected, such as criticize his or

her partner in front of his or her friends or family. In such a situation, the criticized partner may ask, "Why did my partner do that?" The explanation that the criticized partner comes up with is his or her causal attribution of why the event occurred. Attributions are typically studied by presenting people with relationship events and asking them to rate the cause of the event, or the partner's responsibility for the event, along several dimensions. For example, in one prominent line of research, the kinds of causal attributions people make about their partner's behavior are evaluated along the following dimensions: (a) internal reasons (e.g., something about the person) versus external reasons (e.g., something about the situation or circumstances), (b) stable reasons (e.g., something likely to continue over time) versus unstable reasons (something that is transient or time-limited), and (c) global reasons (e.g., something likely to affect many areas of a relationship) versus specific reasons (e.g., something likely to affect only one or a few areas of a relationship). People in distressed relationships make attributions that lessen the impact of positive events and accentuate the impact of negative events, whereas the opposite patterns occur in nondistressed relationships (i.e., the impact of positive events is enhanced and the impact of negative events is negated). For example, people who believe that negative partner behavior is due to internal, stable, and global causes (e.g., a partner's broad and unchangeable traits) tend to be less satisfied with their relationship and exhibit greater declines in their relationship satisfaction over time. Furthermore, people also make responsibility attributions for events in which they judge whether their partner should be blamed for their behavior. Compared with people who are happy with their relationships, people who are unhappy with their relationships tend to blame their partner for relationship problems, viewing their partner's behavior as intentional or selfishly motivated. People who make negative causal and responsibility attributions not only are less satisfied with their relationships but also tend to have less effective problem-solving discussions and behave more negatively toward each other. Finally, it has been shown that the association between attributions and relationship functioning is not due to potential confounding variables, such as personality

(i.e., neuroticism), self-esteem, physical aggression, depression, or measurement procedures.

Relationship Beliefs

Another line of research focuses on the content of relationship beliefs or cognitions. For example, *assumptions* reflect individuals' beliefs about characteristics of their partner and the way that they and their partner relate to one another. Assumptions represent a person's views about the way people and relationships actually are and include beliefs about the partner (such as "My partner is trustworthy") and scripts regarding sequences of events in social contexts (such as the steps involved in forming or ending a relationship). Second, *standards* reflect a person's views about the characteristics that a partner should have or the way that a relationship should be. For example, people often hold standards about how much time they should spend with their partner and what they should be doing during the time spent together. Standards serve as templates against which relationship events and partner behaviors are compared and evaluated. Third, *expectancies* or expectations reflect a person's beliefs about how a partner is likely to behave or about the future status of a relationship. Expectancies often take the form of "if-then" contingency statements such as, "If I am feeling down, then my partner will try to cheer me up." Expectations play a particularly important role in close relationships to the extent that they become self-fulfilling prophecies, which are predictions that become true because they lead people to behave in ways that confirm the expectation. For example, people who expect that their romantic partners will eventually reject them may act in such ways that result in rejection by others. Assumptions, standards, and expectancies can be widely shared by a culture or can be idiosyncratic to a particular individual or couple.

Assumptions, standards, and expectations are not inherently functional or dysfunctional. Rather, they become problematic or dysfunctional when they are extreme, rigidly held, or unattainable or when they are inaccurate in important ways (either as theories about relationships in general or mismatched to the reality of a specific relationship or partner). Dysfunctional relationship assumptions,

standards, and expectations include the beliefs that disagreements between partners are a threat to their relationship, that partners should sense each others' needs without overt communication, that partners cannot change themselves or their relationship, that one must be a "perfect" sexual partner, and that men's and women's relationship needs are radically different. Greater endorsement of these beliefs is associated with lower relationship quality. Furthermore, people tend to be happier in their relationship when they have relationship-oriented standards, such as believing that two people should have a great deal of closeness and sharing, should solve problems in an egalitarian manner, and should be highly invested in giving to the relationship. Finally, greater relationship satisfaction is associated with greater consistency or agreement between individuals' assessment of their current partner and relationship and their ideal partner and relationship.

A second set of general relationship cognitions that have been linked with relationship outcomes concerns people's implicit theories about ideal partners and ideal relationships. For example, research by C. Raymond Knee and colleagues has shown that people differ in whether their implicit theories emphasize destiny versus growth. People who believe in romantic destiny think that potential relationship partners are either meant for each other or they are not, and they emphasize the romantic ideal of finding the right partner. In comparison, people who hold growth beliefs emphasize relationship development over time because of hard work and perseverance. The implicit theories people hold contribute to the meaning assigned to relationship events, thereby influencing not only relationship outcomes but also the way in which people appraise and cope with relationship events, including relationship stressors. For example, early dissatisfaction in dating relationships has been shown to predict breakups for people whose implicit theories emphasize destiny but not for people whose implicit theories emphasize growth.

Memories

Memories about relationships is another important area of research on relationship cognition because individuals' evaluations of their relationships in the

present and their predictions of how their relationships might change in the future are likely to be based, at least in part, upon their memories of the past. For example, research has shown that retrospective reports of relationships differ from how relationships actually develop. Specifically, partners appear to be biased toward remembering the past in such a way that lets them perceive improvements over time. For example, spouses tend to remember declines in relationship satisfaction in the distant past but improvements in the more recent past, even when their satisfaction actually declined over time. Furthermore, as memories of the recent past recede into the distant past over time, it appears that people revise their memories so that they continue to recall improvements only in the recent past. Such memory biases may provide a sense that relationships are progressing and improving, regardless of current levels of relationship satisfaction. Viewing the recent past more favorably than the distant past may also help to see improvements as having taken place recently and declines as having taken place in the distant past. In short, memory biases such as these appear to help people see their relationships as improving, which may contribute to their optimism that their relationship will be even better in the future.

Motivated Cognition

Motivated cognition is a line of research that examines the cognitive processes that allow individuals to dispel doubt and sustain conviction in the face of less-than-perfect partners and relationships. Research by Sandra Murray and colleagues has shown that in general people tend to judge their partners with positive illusions in which the partner is portrayed in the most positive light possible. In these studies, people rate themselves, their partner, their ideal partner, and a typical partner on interpersonally oriented virtues and faults. Individuals' ratings of their current partners are associated with their ratings of their ideal partners, suggesting that images of an ideal partner color perceptions of a partner's actual traits. In addition, people tend to idealize their partners, rating them more positively than their partners rate themselves. Furthermore, individuals are happier in their relationships when they idealize their

partners and their partners idealize them. Idealization also appears to have self-fulfilling effects insofar as (a) people come to share their partners' idealized images of them over time, and (b) people who idealize each other become more satisfied with their relationships over time and are more likely to stay together. Finally, people's motivation to sustain positive images of their partner results in cognitive restructuring processes such as elevating or embellishing the importance of positive characteristics of a partner or by downplaying or minimizing the significance of negative characteristics in a partner.

Working Models and Rejection Sensitivity

In writing about Attachment Theory, John Bowlby proposed that the quality of infant-caregiver bonds influence relationships in later life through the development of internal working models. In particular, based on the quality of early interactions with caregivers, people develop (a) models of the self as worthy or unworthy of love and caring and (b) models of other people as available and responsive or unavailable and unresponsive. As applied to the study of adult relationships, early research tried to assess adults in terms of attachment types or styles that paralleled research on infant-caregiver attachment. More recently, research on internal working models in close relationships has generally focused on the underlying dimensions of anxiety (the degree to which a person holds negative views of himself or herself as a relationship partner) and avoidance (the degree to which a person holds negative views of others). Research on working models typically involves self-report instruments for assessing attachment dimensions. Although a comprehensive review of existing research is beyond the scope of this entry, a large body of research has found that internal working models are associated with relationship outcomes. In brief, this research shows that lower levels of anxiety and avoidance predict better relationship outcomes. Research is also being done to examine the degree of continuity of attachment and working models over the life span and across different relationships.

A cognitive-affective processing disposition that also draws from the theoretical models of Bowlby's

is *rejection sensitivity*. Introduced by Geraldine Downey and her colleagues, rejection sensitivity refers to a disposition to anxiously expect, readily perceive, and easily overreact to perceived rejection. Compared with people low in rejection sensitivity, people high in rejection sensitivity report less satisfaction in their close relationships and their relationships are more likely to break up. On days preceded by conflict, partners of people high in rejection sensitivity experience greater relationship dissatisfaction and are more likely to consider ending the relationship. Furthermore, in a laboratory interaction session, people high in rejection sensitivity behaved more negatively, resulting in greater levels of partner anger after the interaction. Thus, rejection sensitivity may serve as a self-fulfilling prophecy in which people who anxiously expecting rejection perceive intentional rejection in their partner's ambiguous behavior, which in turn leads them to respond with negative behavior that, if unjustified or exaggerated, may elicit greater rejection from their partner, leading to confirmation of their rejection expectancies.

Self-Concept

Relationship outcomes have also been shown to be influenced by self-concept. In general, people assume that other people view them as they view themselves. For example, people with low self-esteem underestimate how positively their dating or married partners see them. Furthermore, self-esteem may serve as a gauge or sociometer that monitors self-acceptance so that feelings of self-doubt alert people to the possibility of social rejection or exclusion, thereby motivating compensatory behavior. In addition, the self-concept serves two important functions. First, people generally seek feedback that enhances the self-concept and allows one to think positively of oneself. That is, people tend to seek out and associate with people who help them feel good about themselves. Therefore, one function of the self-concept is self-enhancement. Second, people tend to seek feedback that confirms or verifies existing self-concepts, as this verification helps to make life more predictable and provides a feeling of security. Thus, a second function of the self-concept is self-verification. For people who have positive self-concepts, self-enhancement and self-verification

work together in tandem: Positive social interaction both enhances and verifies their self-concept. In comparison, the situation is more complex for people with negative self-concepts (i.e., people with low self-esteem). Positive evaluations from others serve to make people with negative self-concepts feel good about themselves but threaten their negative self-concepts, whereas negative evaluations from others confirm their negative self-concepts but make them feel bad about themselves. Thus, these two functions of the self-concept are at odds for people with negative self-concepts. Furthermore, self-enhancement and self-verification appear to differ in importance depending upon the kind of close relationship. Whereas self-enhancement appears to be more important for dating relationships (dating persons are most intimate with partners who evaluate them favorably), self-verification appears to be more important for committed relationships such as marriage. For married people with negative self-concepts, this translates into greater levels of intimacy for people whose spouses evaluate them more negatively.

Information Processing

Much of the research on cognition in close relationships has been conducted with self-report measures in which people rate how much they agree with items representing a particular belief, based on the assumption that people can and are willing to accurately report on the content of their beliefs. A different line of research has focused on how people perceive, interpret, store, recall, and act on information about their interpersonal experiences. For example, research by Susan Andersen and her colleagues has shown that significant others have distinct mental representations that are typically chronically accessible and affect individuals' views of other people. Upon meeting a new person that resembles a particular significant other in some way, the significant other's schema will be activated and the new person will be responded to in many ways as if he or she were the significant other, much like the clinical construct of transference.

Relative to the literature on self-report measures of relationship cognitions, there has been comparatively little research on information-processing measures. However, what research has been done

suggests these methods may be useful for understanding relationship functioning. For example, people classify and organize information in terms of social relationships: Information about relationship partners is stored together, and this is done more for close relationships (e.g., marriage) than it is for distant relationships (e.g., acquaintanceship). Furthermore, when individuals in relationships are given a list of traits and asked whether the traits describe them, people have more difficulty in making me-not me judgments for the traits in which they differ from their partner than they do for traits in which they resemble their partner. This suggests that cognitive processes tend to blur the boundaries between relationship partners and the self. Continued research involving information processing methods should help increase understanding of how people notice, store, and recall relationship information.

COHABITATION

Cohabitation refers to partners in a romantic relationship who are living together without being married. Although this definition seems straightforward, there is some confusion in the research literature and among people in general as to what specific living arrangements are considered cohabitation. Are partners who have separate apartments but who spend most nights together cohabiting? If a couple first began living together as friends or roommates, are they cohabiting once their relationship becomes romantic? For the purposes of this entry, cohabitation will refer to unmarried romantic relationships in which partners share a single address without having separate residences. Thus, the answer to the first question would be no, but to the latter, it is yes.

Demographics of Cohabitation

The recent decades have seen a dramatic increase in cohabitation in the United States, as well as in Canada and in many Western European countries. The following statistics are from the United States, though many of these trends apply to other countries, too. From 1960 to 2000, there was more than a tenfold increase in the number of cohabiting couples. Further, around 70 percent of couples live together before marriage. These figures coincide with other notable changes with regard to marriage in the United States, including a rise in divorce rates over the past 5 decades (though they have leveled off more recently) and a later and later average age for first marriage.

Many cohabiting couples have children, whether their own or from previous relationships. As many as 40 percent of cohabiting couples have children residing with them, and 20 percent of children born in the 1990s will reside in a cohabiting household at some point while growing up.

Cohabiting Before Marriage: The Cohabitation Effect

Many studies in the United States, and in some other countries, find that couples who cohabit prior to marriage are more likely to have difficulties in their marriages and to divorce. This phenomenon has been somewhat of a mystery for social scientists, and something that is barely believable to the average person. After all, most people, especially young people, assume that trying out living together should improve the odds of doing well in marriage. Yet no study supports this idea. On average, those who cohabit prior to marriage are more likely to divorce, are less happy in their marriages, have higher levels of conflict, and have less confidence about their futures. This association with poorer outcomes in marriage is called the *cohabitation effect*. Like any other area of research, such findings are about what happens on average; there are many couples who would be exceptions to the general trend. Many couples who cohabit beforehand have fine marriages, and many couples who do not cohabit end up divorcing. Yet, on average, the data consistently show a higher risk associated with cohabitation. Although some social scientists expected that higher risks would no longer be found once cohabiting was more widely accepted, the newest studies continue to show the cohabitation effect.

Selection Versus Experience

The fact that the cohabitation effect occurs is not disputed among social scientists. What is debated is why it occurs. There are two fundamental explanations: selection and experience. Selection effects are characteristics of people that make them more likely to behave in certain ways. These behaviors then might be related to a particular outcome. For example, a study may find that eating more celery is linked with living longer. Would this finding suggest that all of us should be on a high-celery diet? Not really. Such a finding would have more to do with the fact that those who eat more celery also tend to have more vegetables and less fat, overall, in their diets. The result would be less about celery and more about the other characteristics of those who eat celery.

There are a number of ways in which people who cohabit before marriage differ from those who

do not. For example, those who do not cohabit tend to be more traditionally religious and are more likely to have parents who stayed married. People who are more religious are somewhat more likely to have successful marriages, and those with divorced parents are more likely to struggle in their own marriages. Thus, people who are less at risk for difficulties in marriage are less likely to cohabit prior to marriage in the first place. The selection perspective argues that such risks are present before cohabiting and that there is nothing about the experience of cohabitation itself that causes divorce.

Does selection explain the cohabitation effect? A number of researchers have begun to question if the cohabitation effect can be explained entirely by selection. If selection does not explain it fully, what else might? One answer found by some researchers is that cohabiting prior to marriage with more partners, or for longer periods of time with one partner, is associated with a change in attitudes about marriage. Essentially, people start to value marriage (and having children) less the more they cohabit. This research suggests that the experience of cohabiting erodes values about marriage and family. In turn, valuing marriage less could increase one's risk for divorce.

Inertia

Scott Stanley, Galena Rhoades, and Howard Markman have suggested an experience-based perspective for the cohabitation effect that provides an intuitive explanation. Based on prior work in the area of commitment theory, they note that no matter what else may be true, it is harder to break up when cohabiting than when dating. It is harder to exit a relationship when exiting means partners have to divide up property or friends, move possessions, break a lease, or give up a pet. It could be as emotionally difficult to break up when seriously dating as when cohabiting, but there are all these extra constraints to breaking up when two people cohabit—especially if neither partner has another place that is readily available. In essence, these researchers argue that there is stronger *inertia* in cohabiting than in dating. In physics, inertia represents the amount of energy it takes to move an object that is at rest or to change the direction of an object already moving. About 50 percent of cohabiting couples break up instead of marrying,

but breaking up is likely harder for them than it is for dating couples.

This theory of inertia suggests that cohabiting might lead some poorly matched partners to marry, even though they would not have chosen to marry if they had not already been living together. There is already considerable evidence for this notion that inertia explains some of the cohabitation effect. For example, inertia suggests that some cohabiting couples stay together because it becomes too hard to break up; those who began cohabiting only after they were already engaged cannot be as likely to marry because of inertia as couples who started cohabiting before they committed to marriage. Some research suggests that couples who cohabit only after becoming engaged are at no greater risk for marriage difficulties than those who do not cohabit at all before marriage. Based on the available evidence, it will make sense to some couples to wait until marriage to live together. For other couples who intend to cohabit, it looks like it is particularly important for the two partners to make a mutual decision about the future before they limit their options through the constraints and inertia associated with cohabitation.

Sliding Versus Deciding

The theory of inertia emphasizes the nature of relationship commitment at the beginning of cohabitation. Couples who are clearly and mutually committed to marriage when they move in together are less likely to experience the cohabitation effect. But how do most couples begin to cohabit? Researchers Wendy Manning and Pamela Smock have conducted extensive interviews with couples who are cohabiting in the United States. They find that virtually no couples talk about the transition into cohabiting. Rather, most slide into cohabitation. They rarely discuss the meaning of the change or their levels of commitment to each other first. Stanley and colleagues hypothesize that, for all kinds of major relationship transitions (e.g., having sex for the first time, becoming pregnant, cohabiting), sliding is associated with more risk than deciding. The paradoxical risks of cohabiting prior to marriage continue to be studied by numerous research teams, which should mean the cohabitation effect will be increasingly well understood in the years to come.

Cohabitation Versus Marriage

Because more couples than ever before cohabit instead of or before marriage, researchers have studied differences between married and cohabiting couples. This comparison is far harder to make than one might think. For example, married couples tend to have been together much longer than cohabiting couples. On the one hand, because most couples tend to experience a decline in happiness over time, comparisons between long-time married couples and cohabiting couples would be biased in favor of showing cohabiting couples to be, on average, happier. On the other hand, couples who make it through many years of marriage are a special group, having survived many difficult and challenging times together. Therefore, samples of long-time married couples tend to include many very happy couples. This is just one example of how difficult it is to properly compare cohabiting versus married couples. Nevertheless, after carefully accounting for the complex nature of this comparison, researchers have found several important differences between cohabiting and married couples.

Generally, cohabiting couples tend to look more like dating couples than married couples on various measures. All other things being equal, individuals who are cohabiting tend to report less satisfaction with their relationships, lower levels of dedication (a type of commitment) to their partners, and more problems with infidelity. They also tend to have more problems with alcohol and depression than people who are married.

The growing trend for couples to cohabit rather than marry, or cohabit prior to marriage, has changed the landscape for how couples and families form. Although most research has focused on first marriages, this phenomenon extends to post divorce unions as well as elderly and widowed adults who may choose to cohabit rather than marry to avoid comingling finances or upsetting family members. There will be much future research on the nature, meaning, and effects of cohabitation because it has become such a prevalent part of couple and family development.

COHESIVENESS IN GROUPS

When scholars think about factors that cause people to remain in groups and work to achieve collective goals, *group cohesiveness* comes to mind. There is a general belief that cohesiveness has positive consequences for group processes and outcomes, and therefore, leaders should try to instill

and maintain it. But is this effort really worthwhile? To answer this question, it is necessary to consider how the term *cohesiveness* is defined, the techniques used to measure it, the factors that produce it, and finally, the impact it has on groups. Each of these issues is discussed in this entry.

Definitions and Measures of Cohesiveness

The earliest formal definition of cohesiveness in social psychology was offered by Leon Festinger, Stanley Schachter, and Kurt Back in their research on the operation of group standards. Writing in 1950, Festinger and colleagues defined cohesiveness as “the total field of forces which act on members to remain in the group” (p. 164). This definition views cohesiveness as a force that binds members to a group. Many later definitions of cohesiveness were offered, but most focused on some form of attraction. According to one view, cohesiveness arises from mutual attraction between interacting group members based on their similarity to one another or ability to satisfy important goals. This has been labeled *personal attraction*. According to a second view, cohesiveness depends on how much members like the group as a whole rather than how much they like individual members. Finally, a third view combines the above two ideas by suggesting that cohesiveness is based on members’ attraction to others who possess prototypical characteristics that differentiate the ingroups from outgroups. In other words, rather than being attracted to people because of their unique personal qualities, group members are attracted to those who embody qualities that make the ingroup distinctive. This has been labeled *social attraction*.

Several techniques have been used to measure cohesiveness. Some of these involve monitoring group members’ behavior. For example, researchers have observed various aspects of members’ verbal and nonverbal interactions (e.g., use of jargon and plural pronouns, physical proximity to one another, eye contact). Other techniques involve questioning members about their feelings or perceptions regarding one another or the group as a whole. For example, members are sometimes asked how much they like specific others or the entire group, how strong a sense of belonging they feel, how much they want to remain in the group, how close the

group is, and so on. Several questionnaires have been developed to measure cohesiveness, some focusing on particular kinds of groups (e.g., sports teams) and others focusing on groups in general. These questionnaires vary widely in the topics they cover and the aspects of cohesiveness they assess. Not surprisingly, controversy exists regarding the best means of measuring cohesiveness.

Antecedents of Cohesiveness

Most of the work on causes of cohesiveness has focused on determinants of personal attraction, as defined above. Research indicates, for example, that physical proximity and interaction between group members enhances cohesiveness, though this is less likely if contact is forced by an external agent and if members are initially hostile toward one another, perhaps because of different racial or ethnic backgrounds. In general, members like one another better when they work cooperatively rather than competitively, feel accepted rather than rejected, and are similar rather than dissimilar on such characteristics as religion, race, and values, particularly when these characteristics are viewed as important. Although it might seem obvious that threat to a group would enhance members’ cohesiveness because members are all in the same (leaky) boat and need to work together, this is not always the case. In fact, threat only increases cohesiveness under certain conditions—when it is imposed from outside the group, is widely shared among members, is not blamed on particular members, and is seen as something that members cannot escape on their own. Similarly, it might seem obvious that cohesiveness would be higher in successful rather than failing groups because success produces positive feelings toward everything about the group (including other members), but this too is not always the case. Although the reason that failing groups sometimes have high cohesiveness is not entirely clear, one possibility is that members of such groups need to rationalize their sacrifices. This in turn may motivate them to see their coworkers in a positive light, perhaps by exaggerating their effort on the group task.

In recent years, increased attention has been devoted to the causes of social attraction, as defined above. Evidence indicates that cues that

increase the salience of the ingroup (e.g., intergroup competition) stimulate individuals to self-categorize as ingroup members, which in turn produces attraction to other members who embody prototypical ingroup characteristics. When this type of self-categorization occurs, attraction to ingroup members does not depend on their unique personal qualities (e.g., kindness, sense of humor) but rather on their embodiment of characteristics that differentiate the ingroup from outgroups (e.g., athletic ability in the case of groups that view themselves as highly athletic).

Consequences of Cohesiveness

Several consequences of cohesiveness based on personal attraction have been identified. For example, members of cohesive groups are generally more satisfied and less anxious than are members of noncohesive groups, though cohesiveness can produce distress under some conditions (e.g., when soldiers in cohesive units lose comrades in battle). Cohesiveness can also influence group processes in various ways. Compared to members of noncohesive groups, members of cohesive groups are more likely to communicate with one another, conform to group norms, and react negatively to people who violate these norms. These latter two reactions can have negative consequences if they cause groups to reach premature consensus on an issue and then ignore or punish those who challenge this consensus, as happens in cases of groupthink. This example raises the more general question of how group cohesiveness relates to group performance. In a 1994 review article, Brian Mullen and Carolyn Copper concluded that cohesive groups often outperform noncohesive groups in both laboratory and real-world settings. Moreover, the causal arrow between cohesiveness and performance runs in both directions. Not only does higher cohesiveness produce higher performance, but higher performance also produces higher cohesiveness. Finally, the impact of cohesiveness on performance depends on the group's productivity norm. When that norm encourages productivity, cohesiveness facilitates performance. But when that norm discourages productivity (e.g., because members feel underpaid), cohesiveness undermines performance. In sum, the impact

of cohesiveness on group processes and outcomes is far from simple.

COLLECTIVISM, EFFECTS ON RELATIONSHIPS

Collectivism is a cultural syndrome, a network of norms, values, and ways of engaging the world embedded in practices, artifacts, institutions, language use and structure, and ways of making sense of history. A central theme of collectivism as a cultural syndrome is that relationships with relevant others and group memberships constitute the primary unit of society, the foundation of self-concept, and the key values that should govern one's life. Social units that share a common fate are centrally important from a collectivistic worldview, which highlights interdependence among ingroup members and relevant values, such as loyalty and perseverance. These social units can be broadly defined as groups with which a real or symbolic blood tie exists (families, tribes, races/ethnicities, religions, nations, peoples) as well as, in some situations, civic (neighborhood or community) or other working groups.

Within a collectivistic perspective, each social unit feels tangible and real, and group members are obligated to and interdependent with each other. In

this way, group memberships and the relationships they entail are permanent, fixed facts of life that are indefinitely obligating. Within a collectivistic perspective, individuals can only be understood within the context of the groups they belong to and in terms of their connections with particular others. Group memberships are assumed to be stable, impermeable, and central to self-concept. Fulfilling one's obligations to group members and collective welfare are therefore central to well-being, while communicating and pursuing one's personal goals and desires is assumed to be at best a secondary issue. The alternative to a collective perspective is an *individualistic perspective* in which the individual is the most basic unit of society. Individuals are defined by their own attainments and relationships, and group memberships have meaning only insofar as they facilitate the attainment of personal goals. This entry describes theory and research about collectivism and its effects on relationships.

Theoretical Implications of Collectivism: Impact on Relationship, Values, Self-Concept, and Cognition

A collectivistic worldview should have important consequences for how relationships are conceptualized, what is perceived to be of value, and how the self is conceptualized. When perceived through a collectivistic view, a primary human goal is to maintain important group memberships and the necessary interpersonal relationships that group memberships create. This requires focusing on fitting in and appropriately engaging in social contexts. Figuring out what is appropriate requires skill in indirect communication (reading between the lines of communication and making inferences given context, tone of voice, and other cues) and the ability to restrain oneself, not stick out or offend ingroup others.

To maintain harmony in relationships with ingroup others requires a heightened sensitivity to interpersonal contextual cues including concerns for belongingness, dependency, empathy, norms for reciprocity, and occupying an appropriate place within the relationship hierarchy. These relationships require detailed interpersonal knowledge and constant awareness of others, their needs, desires, and goals. Thus, satisfying one's own need

to connect with others may best be met by satisfying others' needs. One perspective on how to fit in and anticipate the needs of ingroup others comes from an East-Asian Confucian-based perspective. From this perspective, individuals are socialized to effectively regulate and control their own emotional displays, smoothing out both displays of negative and positive emotions in settings where either may offend others. Another perspective comes from African, Mediterranean, Middle-Eastern, and Latin perspectives that emphasize ingroup others as important sources of honor. Honor-based collectivism also emphasizes that the self is defined by ingroup others but does not necessarily focus attention on regulation of emotional expression. Rather, in these contexts, displays of anger, hostility, and other strong emotions can be appropriate ways to mend and restore honor. A drawback of research to date on collective worldview and relationships is that it mostly contrasts Eastern (Asian) and Western (especially North American) societies, suggesting that results so far may be limited to a certain kind of collectivism.

Engaging in collectivism-appropriate relationships requires that one's values, goals, and thoughts about the self make sense within these relationships. From a collectivistic perspective, relationships with others are not merely connected to self-concept; they are the central, defining feature of self-concept. Without one's relationships, one would not be the same person. In this way, collectivism is centrally defined by a connection between (rather than a separation from) the self and relevant others.

Indeed, to make sense of gender differences and cross-cultural differences between Eastern (e.g., Japan) versus Western (e.g., United States) societies, researchers have contrasted interdependent and independent ways of defining the self and linked these differences in self-concept to differences in cognitive processes. This research finds consistent cross-national differences in relational styles that parallel differences in perception and cognition, how stimuli are perceived, the sense made of information and conclusions drawn from information as well as what feels convincing and worthy of attention.

Assessing Collectivism and Its Effects

An important early operationalization of collectivism was provided by Geert Hofstede in his

1980 book, *Culture's Consequences*. He conceptualized a single scale with low individualism (high collectivism) anchoring one end and high individualism (low collectivism) anchoring the other. Hofstede identified this factor by factor-analyzing work-related value questions across 65 nations. In doing so, he organized the myriad possible ways in which countries could differ into a small number of specific factors (with individualism being the first and most widely studied focus of attention). Averaged responses were used to create country scores, which he demonstrated were correlated with nation-level variables such as population size and gross national product.

Although Hofstede did not argue that his findings should be assumed to be fixed in time, since 1980, others have applied his results in making sense of their own cross-national comparisons, inferring that observed differences in samples drawn from two different nations are due to differences in individualism or collectivism. Indeed, a large number of country-country comparisons find results compatible with the notion that nations differ in collectivism and in individualism. However, there are three main criticisms of this approach and the studies that use it. First, these studies do not lay out the process connecting country-level differences in individualism or collectivism and individual differences in dependent variables of interest such as relational style. Second, they typically demonstrate that differences exist between countries but do not directly link these differences to individualism and collectivism. Third, by inferring that difference is due to individualism and collectivism, these studies cannot separately assess impact of individualism and collectivism. To address these shortcomings, some studies include a direct assessment of individualism and collectivism (study participants are asked to describe their values, attitudes, and norms). This allows for direct assessment of the link between individualism or collectivism and outcomes of interest such as relationship style.

This approach also can be criticized because collectivism is operationalized as a set of responses to value, attitude, and norm questions. A separate literature has shown that self-reports are highly influenced by the context in which they are asked; the answers one gives depend on what seems relevant in the moment and what is relevant can be due

to contextual cues one does not even consciously notice. For example, when asked to describe oneself, people are more likely to use personality traits when the study comes from an institute of personality research than from an "institute of social research," even though they are not aware of making this adjustment. In spite of this limitation, research connecting self-reported individualism and collectivism with relationship style has yielded important and theoretically meaningful results, consistent with cross-national comparisons. To examine the overall picture of this research, a quantitative synthesis (meta-analysis) across studies was needed to look for patterns that cannot be seen in a single study. Daphna Oyserman, Heather Coon, and Markus Kemmelmeier performed such a synthesis and suggest three important conclusions. Both individualism and collectivism can be assessed. Countries differ systematically on these measures. Finally, individualism and collectivism scores are not related. That is, high collectivism is not necessarily the same as low individualism.

Why might this be? One possibility is that rather than socialize only for individualism or only for collectivism, societies may actually socialize for both but differ in the situations in which one or the other framework is relevant. Saying that a society is high in collectivism would then simply be a shorthand way of saying that people living in that society usually make sense of themselves, others, and the world within a collectivistic framework but could use an individualistic framework if it seemed relevant in a particular context. A clear example involves engagement with outgroup others. Collectivism does not imply that one engages in a connected and related way with all others, just with ingroup others. When the ingroup is not relevant, one is free to compete with others, express oneself, and follow one's desires.

Empirical Evidence for the Relational Effects of Collectivism (and Individualism)

In their meta-analytic review, Daphna Oyserman and colleagues identified 71 studies examining assumed or assessed effects of individualism and collectivism on relationships of various kinds. Assumed effect studies used cross-national comparisons rather than directly assessing individualism or

collectivism, assuming for example, that if Americans differ from Chinese on a variable interest, the pattern of results can be explained by (unmeasured) differences in individualism or collectivism.

Close relationships were studied in 17 studies, which asked, for example, whether individualistic perspective was associated with romantic love, family obligation, and other close relationships. Effects for romantic love were inconclusive. Similarly, felt closeness and obligation to nuclear family are not a simple function of collectivism. Effects are complicated by the fact that felt obligation can also be perceived as part of a chosen relationship, and this seems to be how Americans tend to view their family relationships. Generally, research did not support the notion that Americans have more conflicted family and intimate relations than others but did support the idea that individualism promotes ease of interacting with strangers and more direct communication styles, while collectivism promotes ingroup preference in relationships and different forms of face-saving. Effects were substantial, often moderate to large in size, though highly variable by study and outcome. Study results suggest more freedom to choose interaction partners and lower relationship commitment and engagement with a larger group of less close others when individualism is high, but higher conformity and more time spent with ingroups rather than outgroups when collectivism is high. For example, although interacting with strangers is always more difficult than interacting with ingroup members, Japanese and Koreans report a larger difference than Americans in how they act with ingroup members versus strangers. Americans interact with more people, more frequently, whether individually or in groups, than do Hong Kong–Chinese students.

Another 38 studies examined interactions within and across groups, showing for example that a preference for forming relationships with ingroup others over outgroup others is associated with collectivism. A final 16 studies examined workplace relationships such as supervisor plans to motivate employees. These studies found that American supervisors were more likely to prefer direct communication, individual-level rewards, and tit for tat responses (e.g., immediately reward good behavior and punish bad behavior) rather than respond more indirectly or provide longer-term, group-level

rewards and responses. Here too the average effects of individualism and collectivism on relationships and relationship styles were substantial.

Of course, the question remains whether these cross-national results are actually due to individualism, collectivism, or perhaps something else. Daphna Oyserman and Wing Sing (Spike) Lee conducted a second meta-analytic review to address this question and found 13 studies examining relevant outcomes (relationship style, felt support, closeness, cooperation, and social obligation). These studies leverage prior research, demonstrating that self-reports and behavior are highly influenced by contextual cues, to prime (or to make momentarily salient) relevant active ingredients of either individualism or collectivism. For example, participants were asked to read a paragraph about a trip to the city that either included the pronouns I, me, and myself (individualism prime) or the pronouns we, us, and ourselves (collectivism prime). Researchers found that on average, the answers participants gave to the relationship questions depended on whether they had just circled singular or plural pronouns. Collectivism-primed participants felt more obligated to help, made more prosocial choices, and were more in favor of affirmative action, suggesting that when made salient in the moment, a collective worldview facilitates greater social obligation and cooperation with others.

COMMERCIAL CHANNELS FOR MATE SEEKING

Commercial channels for mate seeking and dating are one form of marriage market intermediary (MMI). Sociologists often speak of mate selection occurring in the “marriage market,” by which they mean the system of social and commercial institutions that facilitate courtship. Like all markets, the marriage market attempts to improve the efficiency of searching for information, making decisions, and conducting transactions (which researchers have called interacting in the context of social relationships). MMIs, like intermediaries in other markets, can be understood in terms of their ability to help with one or more of these functions (see Figure 1).

Some MMIs, like singles ads, primarily help to reduce search costs by providing and organizing information about eligible others. Others such as traditional matchmakers or Web sites such as eHarmony.com go beyond providing information and help the single choose with whom to interact. Finally, some MMIs also influence and structure the interactions themselves. For example, many traditional matchmakers provide dating advice along with the introductions. Similarly, speed dating in which clients meet a series of eligible others in rapid succession is popular in part because many clients like the way it structures the initial phases of interaction. Although overt commercial MMIs usually advertise themselves as helping singles find a long-term relationship, even when that goal is not achieved, many singles report secondary psychological benefits from meeting available others and in some cases, report positive interactions with matchmakers or other urban agents.

There is a pervasive myth that either singles use overt commercial MMIs such as dating services, or

Figure 1 Functions of Marriage Markets

they try to find a mate on their own. This view overlooks the pervasive nature of MMIs (see Figure 2). MMIs can be overt, such as a dating service, or semicovert, such as a nightclub where many customers pay in part for the opportunity to meet eligible others. For example, for many years there were pervasive stereotypes about women attending college to get their “Mrs. degree,” revealing that for some families, paying college tuition for their daughters was at least in part purchasing access to a semicovert MMI. Another distinction within MMIs is that they can either be commercial or noncommercial in nature, and many MMIs are run as part of broader social institutions such as with churches. Over the past 20 years, we have seen a shift toward more commercial MMIs and in some cases, toward more overt MMIs, although semicovert MMIs such as *Facebook* and other Internet social networking sites are thriving as well.

History of MMIs

The growth of commercial MMIs constitutes a third phase in the history of courtship in Europe and in the United States. The long first phase took place prior to the Romantic period, which began in the second half of the 18th century. In this first phase, marriage was seen primarily as a practical arrangement. For most of the population, this

Figure 2 A Typology of MMIs, With Examples

meant a pragmatic partnership for building a home and family, hopefully where love would also be found. For the few elites, it included issues of family prestige and occasionally politics. The choice of marriage partners was strongly influenced by the family of the bride and groom, with the individuals having more or less say depending on the local culture. This social system created inevitable conflicts since, in the words of Blaise Pascal (1623–1662), “The heart has its reasons of which reason knows nothing,” and people on occasion would fall in love—Romeo- and Juliet-like—with partners of which their families did not approve. But since individuals were highly dependent on their families for economic opportunities and social legitimacy, the family usually won out in the end. During this phase, commercial MMIs in the form of matchmakers were limited to occasional use by elites and by dispersed populations such as European Jewry, where traveling scholars or full-time professional matchmakers would help families in small isolated communities find marriage partners for their children.

The second phase began in earnest in the mid-18th century as Europe grew richer and more educated. Intellectual trends such as individualism combined with growing economic independence of individuals from their families began to shift the balance of power away from families and toward singles themselves in the choice of marriage partners. A larger social and intellectual movement, called Romanticism, placed a priority on individual self-expression and saw passion in a positive light as an expression of the life force. The Romantics’ ideas about love (i.e., romantic love) slowly came to dominate European and American social discourse. By the 1920s, a new social institution, dating, was born, and courtship moved out of the parlor where it was supervised by the family and into the public space of the restaurant or movie theater and often into the private space of the car. Very gradually, in a trend that continued from the 1800s to the 1970s, marriage became redefined from a practical social arrangement reflecting both individual and family interests to the formal public recognition of a private romantic love.

Before the Romantic period, commercial MMIs were not widely popular because most people had little need for them. Romanticism increased the potential demand for commercial MMIs by

insisting that marriage be based on love, and thus, people should be highly selective in whom they marry. But at the same time, the Romantic worldview made overt MMIs ideologically unattractive. Romanticism saw love as a supernatural force existing outside of conventional social institutions and cast courtship as an individual heroic quest for life meaning, personal identity, and a kind of terrestrial salvation. Hence, the use of a commercial MMI would profane love’s sacred essence and was the admission of personal failure on a heroic quest. This explains why the use of commercial MMIs was widely seen as “for losers” who were incapable of finding love on their own, whereas this stigma did not exist for other services (e.g., no one says a restaurant is for losers who cannot cook their own dinner).

The third phase began in the 1980s with the rise of commercial MMIs as a complement to more traditional semicovert MMIs. Commercial MMIs first became popular with single professionals in their late 20s through early 40s. Many of these people had moved away from the place where they had grown up, only to find themselves ready to marry, no longer involved with high school or college sweethearts, separated from earlier social networks, and working in corporate environments where dating within the company was discouraged. These demographic changes created a tremendous practical demand for MMIs of all kinds, but their growth was slow because romantic views of love still produced strong stigmas against using overt MMIs and semicovert MMIs were of limited efficiency. Commercial MMIs used two main strategies to overcome this stigma: keeping users identities highly confidential and in some cases, promoting an elite upscale image complete with user fees ranging from \$2,500 to \$50,000. The spread of commercial MMIs was also aided by the fact that their main target market, single young urban professionals (i.e., yuppies), had disposable income and were accustomed to purchasing professional services from house cleaning to personal athletic trainers.

It is important to note that the growth of MMIs began before the rise of the Internet due to demographic changes such as later marriage and transient single populations, but technology acted as a remarkable accelerant on their spread. The first big technological change was the development of

fee-for-use 1-900 phone numbers. Prior to these 1-900 numbers, the person placing the ad paid a fee, usually \$40 to \$80, to place a small, unsigned, classified ad in the singles section of a newspaper or magazine. Interested others would respond in writing via the publication. In this system, the advertiser bore most of the time and all of the financial costs, which kept the number of advertisers fairly low. With the advent of 1-900 numbers, placing a singles ad became free, and the financial costs were borne by the responder who paid a fee to leave a voice message for the advertiser. This generated a dramatic increase in advertisers, which in turn led to an increase in responders, and commercial MMIs started to break through into the mainstream. Thus began a self-reinforcing cycle in which as more people used these MMIs, the stigma attached to them decreased, which in turn led to wider use, and so on, until the stigma based in a romantic worldview gradually started to crumble before the practical benefits that MMIs were able to provide a large population of singles.

The stage was well set for the arrival of the Internet, which has made commercial MMIs mainstream among postcollege singles today to the extent that a report from the Pew Internet & American Life Project finds that “most online Americans who are single and looking for dates have used the Internet to pursue their romantic interests” (<http://www.perfspot.com/docs/96>). Today, the mate-seeking industry, especially online, is big business. Global revenues have been quoted as the “multibillion-dollar love story” and climbing. In China alone, such dating services produced \$11.2 million in 2005 and are predicted to increase to \$81 million by 2008.

Clearly, the stigma in using an overt commercialized service is greatly diminished, despite the criticism that MMIs represent a “McDonaldizing” of romance that is systematizing, rationalizing, and rendering into a calculative mate quest what is supposed to be a magical process. Notwithstanding this criticism, some researchers contest the idea of McDonaldized romance and suggest that commercial MMIs, particularly online ones, are a historical outcome of highly fragmented postmodern societies defined by growing mobility, open-access technology, and uncertainty. As such, commercial MMIs can be considered integral to social life in posttraditional cultures and are more aptly

characterized by “eBayization” where the personal and the market merge into one than by a McDonaldized factory model. Interestingly, although commercial services such as Match.com or eHarmony.com continue to do very well, by far the largest Internet MMIs are multipurpose Internet 2.0 Web sites. Commercial Web sites such as *Facebook* connect people for all sorts of social interactions but include information on gender, sexual orientation, relationship status, and relationship goals, specifically to augment their utility as MMIs for singles who now find commercial MMIs nonremarkable. Whereas the primary social concern about commercial MMIs used to be the romantic stigma that they were for “losers,” today the primary concerns revolve around safety and the fear that these MMIs are so widely used that young singles may display more personal information online than is in their long-run interests.

Research on MMIs

Research on MMIs falls into three broad categories. A large group of studies, rather than looking at MMIs themselves, use data from MMIs such as singles ads to understand mate-seeking preferences. Content analysis of ads, for example, provides natural data for examining mate preferences for partners. Much of this work confirms common observations that when evaluating a potential mate, men place a higher priority on physical attractiveness and women place a higher priority on professional success. A second type of research explores MMIs themselves from economic, historical, or sociological perspectives. For example, Beth Bailey provides a historical overview of dating that shows the prevalence of commercial metaphors in mate seeking long before the advent of singles ads. Finally, research in therapeutic fields sometimes explores the ability of overt MMIs to help specific populations acquire social skills or find a romantic partner. One study used interviews to explore the types of social support that clients received from matchmakers, such as having a confidant, creating realistic expectations, and increasing self-esteem.

COMMITMENT, PREDICTORS AND OUTCOMES

If people were in relationships only for fun and enjoyment and ended their relationships the moment the joy subsided, there would not be much point in studying commitment; a psychology

of relationship satisfaction would suffice. However, relationships are more complicated: People stay together despite short-term and even long-term drops in satisfaction, and sometimes couples break apart although their relationship satisfaction may be the envy of others. Such phenomena require a psychology of commitment. Generally, commitment represents the motivation to maintain and sustain a relationship, even in the face of adversity. Although influenced by social factors such as making a public pledge or vow, commitment is experienced in a very personal way as an internal psychological state that motivates the thoughts, feelings, and behaviors that help a relationship survive and maybe even flourish. Commitment has been described as including an attachment bond, a long-term orientation, and the intention to persist. Typically, it is assessed by asking people a series of questions including an explicit question, “How committed are you to this relationship?” Some important issues addressed by commitment research and reviewed in this entry are (1) whether personal reports of commitment predict the survival of a relationship, (2) what factors promote commitment, (3) what thoughts and behaviors does commitment influence that may help relationships survive, and (4) what is the experience of losing a committed relationship.

Predicting Whether Relationships Last

The sine qua non for relationship commitment has been its ability to predict relationship persistence. Data from thousands of participants in dating relationships (who break up at higher rates in shorter time periods than married people) reveal a strong association between relationship commitment and persistence. However, in these types of relationships, satisfaction is highly correlated with commitment, prompting the question of whether it is truly commitment or instead satisfaction that accounts for persistence. Statistical procedures that allow researchers to compare commitment and satisfaction simultaneously find that commitment predicts persistence above and beyond satisfaction, whereas the ability of satisfaction to predict persistence controlling for commitment is weak at best. Remarkably, one study showed that commitment,

rather than satisfaction, predicted whether relationships remained intact 15 years later.

Despite the ability of commitment to predict persistence controlling for relationship satisfaction, the overlap between commitment and satisfaction has often left the wider research community a little skeptical about relationship commitment. Moreover, there has been some suggestion that the use of self-report methods may inflate the degree of overlap because people often use their general evaluation of a relationship as positive or negative (satisfaction) to guide answers to other relationship questions (such as commitment): "If the relationship is good, then I must be committed to it." Prototype analyses of lay conceptions have established that, although commitment and satisfaction are indeed overlapping constructs, they are nevertheless distinct. The challenge for research has been to find ways to disentangle commitment from satisfaction in order to learn more precisely how each of them influences relationships.

One strategy to address the commitment-satisfaction overlap has been to identify or induce experimental situations that provide a stress test of the relationship. The idea is that when the relationship is not easy to maintain, a person may think more carefully about the relationship and ask, "Even though this is not a lot of fun right now, am I prepared to stick with it and work at it?" Alternatively, when faced with a relationship transition, a person faced with an uncertain relationship future may ask, "Even though the relationship is great right now (high satisfaction), am I committed enough to sacrifice a school or job opportunity to move to another city with my partner?" One naturally occurring stress test of commitment occurs when a person leaves home and dating partner to attend a university. In such a context, commitment and satisfaction are weakly correlated, and commitment predicts relationship persistence better than does satisfaction.

Mindset theory suggests that turning points in a relationship such as these might induce a deliberative mindset in which a person evaluates a goal in a relatively impartial manner, weighing the pros and cons of potentially achieving personal or relationship goals. Once a person commits to a course of action in a relationship, the individual has a more implemental mindset, shifting attention to thoughts of how to achieve those goals. In a test of

mindset theory, judgments of relationship commitment made in a deliberative mindset predicted relationship persistence, whereas judgments of relationship commitment in an implemental mindset did not predict persistence. Subsequent research showed that perceptions of a partner's commitment are more accurate in predicting relationship survival when made in a deliberative mindset. Similarly, personal predictions about how long one's relationship will last more accurately forecasts the future survival of the relationship when made in an experimentally induced deliberative mindset than an implemental mindset. Deliberation may be uncomfortable because it embraces uncertainty and because it is often tempting to skip or abbreviate deliberation. However, the accuracy of relationship forecasts is improved by engaging in deliberation.

Factors That Promote Commitment

Satisfaction may be one important factor promoting commitment, but it is not just a matter of how high one's satisfaction is; it is also necessary to consider how much satisfaction fluctuates. A person who consistently feels fairly satisfied may be more committed to a relationship than a person with the same average level of satisfaction but who experiences lots of highs and lows. Fluctuations in satisfaction are associated with decreased commitment and relationship survival, independent of average levels of satisfaction.

Most perspectives on commitment conceptualize two sets of factors that promote commitment: forces that draw people to a relationship and forces that keep people from leaving. These approach and avoidance aspects of commitment were originally described as attractions and barriers. Subsequently, the Investment Model of Commitment used Interdependence Theory to specify attractions and barriers. Attraction depends on the difference between rewards and costs relative to one's personal expectations, summarized as the level of relationship satisfaction. This means that Harry's rewards, for example, may exceed his costs more than Sue's rewards exceed her costs; but if Harry has much higher expectations, he would still be less satisfied and consequently less committed than Sue.

On the barriers side, the lack of alternatives motivates a person to stay in a relationship. Moreover, the level of investment in the relationship is a barrier to leaving because investments become losses once the relationship ends. For example, time and energy invested in a relationship are lost.

In addition to the common two-factor approach to commitment, it has been suggested that there may be an important third element distinct from attractions and barriers. A person may be committed to a relationship because it reflects personal values and has become a source of meaning and identity for the individual. These variables have been associated with what has been termed *moral commitment*, and there is evidence that moral commitment does better than satisfaction-based commitment in predicting relationship persistence. The role of meaning and values in relationship commitment may explain why relationship commitment can effectively protect individuals from an existential fear of death. Historically, religion has offered the hope of literal immortality in response to the reality of physical mortality. Theorists have posited that romantic relationships in the modern era have assumed some of the psychological functions of religion in providing a sense of meaning and purpose to one's existence.

One complexity of moral commitment is that it may be motivated either by personally embraced values that reflect one's identity or by other people's values that one feels some pressure or guilt to endorse. In recent years, research has shown that identifying with a relationship and thinking in terms of "we" rather than "you and I" may be a critical component to commitment. Although it appears that both identity and guilt-based motives predict relationship persistence, identity motives predict increasing relationship satisfaction over time, whereas guilt-driven motives predict decreasing satisfaction.

Moral commitment, values, and identity all indicate that commitment is not simply the result of a cost-benefit analysis. This may seem to depart from earlier formulations. However, it is also possible that values could be considered personal rewards. The difference is that these sorts of rewards are likely to be more stable and less volatile than hedonic rewards, and as such would predict greater commitment and relationship

persistence because of decreased variability in the reward-cost differential. Yet calling everything that helps sustain a relationship a reward may mask important differences between satisfaction and values, sacrificing precision and understanding for the sake of simplicity.

How Commitment Promotes Relationship Persistence

Although different theorists have emphasized different models of commitment, researchers have shared the goal of understanding how relationship commitment leads to persistence. What do people actually do that helps keep their relationships going, and can commitment account for this continuity? Seminal work on prorelationship behaviors stimulated both experimental and naturalistic studies on the ways in which commitment influences affect, cognition, and behavior in a given relationship. Many of these studies can be conceptualized in terms of a buffering model whereby relationship commitment protects the relationship in the face of threats from within or outside of the relationship.

One type of threat is partner transgressions, negative behaviors by the partner, such as forgetting to do something that was important to the other partner or revealing something private to others. There are two dimensions of behavioral responses to transgressions: active versus passive and constructive for versus destructive to the relationship. This two-dimensional space yields four patterns of response: voice (actively responding in a constructive way), loyalty (passively responding in a constructive way), exit (actively responding in a destructive way), and neglect (passively responding in a destructive way). Voice might be discussing the problem with one's partner in a clear, constructive manner. Loyalty would be patiently and quietly hoping that things will improve. Exit would be expressing negative emotion and then leaving the situation. Neglect would be sulking or giving one's partner the cold shoulder. A greater willingness to respond constructively (voice or loyalty) rather than destructively (exit or neglect) was termed *accommodation*, and research found that relationship commitment predicted willingness to accommodate.

Subsequent research has demonstrated that committed individuals appear more motivated to assume that the partner's bad behavior was due to extenuating circumstances rather than not caring, and these attributions make it easier to act in an accommodating, forgiving manner. In addition, committed individuals are less likely to even see their partner's behavior as negative. Research found that this perceptual bias works in tandem with accommodation so that when transgressions are moderate in objective severity, committed individuals minimize the severity and do not need to accommodate, whereas for more severe transgressions, it is more difficult to minimize, and accommodation serves as a second line of defense.

Another type of threat often studied involves responses to an attractive alternative relationship partner. This focus is in part due to the prevalence of research on university students in dating relationships, where the availability of attractive alternatives is a common, ecologically valid relationship threat. The first line of defense appears to be a failure to notice or acknowledge alternatives. In addition to reporting less attention to alternatives, committed individuals actually spend less time looking at attractive alternatives in a controlled lab setting. On the other hand, narcissists are more likely to attend to attractive alternatives and in turn are less committed to their relationships.

The second line of defense is to denigrate the appeal of alternatives. This tendency to "devalue" the attractiveness of alternatives has been studied within a broader framework of calibrating pro-relationship responses to match the level of relationship threat. Consistent with research on stress and coping, when an individual has sufficient resources (in this case sufficient commitment), he or she will ward off threats to the relationship, maybe even appraising them instead as challenges. A person committed to a dating relationship would likely find fault with an attractive person of the opposite sex. However, if a person is not sufficiently committed, then the threat would more likely win out and possibly weaken the relationship, as the low-commitment person is drawn to attractive alternatives and perhaps even infidelity. Of course, acknowledging the appeal of an alternative may not always indicate a lack of commitment, as highly committed partners can feel secure enough to recognize the attractiveness of others—as long

as such attractive others do not become too close or viable alternatives. Even among the highly committed, there are limits to the level of relationship threat that can be ignored or dismissed.

Whereas relationship commitment may motivate people to devalue the attractiveness of alternatives, it conversely appears to motivate embellished and idealized views of one's partner. Committed individuals are more likely to perceive their partners to be better than others, and this effect is most pronounced when people are asked to be accurate, or deliberate, about the true merits of the relationship. The idea here is that the demand to be accurate or deliberative threatens to unmask relationship illusions, and committed individuals compensate by exaggerating further their already positive views of their partner.

This perceived superiority or better-than-average effect is a milder version of the relationship illusions effect, a process whereby intimates see their partners more positively than even the partners see themselves. Given the positivity of self-views, this effect is particularly surprising. However, one group of individuals that consistently fails to show this bias is men in dating relationships. It has been theorized that because women identify with relationships in general, they would show a bias right from the beginning of their relationship, whereas men, who generally do not identify with their social network of relationships, do not show this bias. Research has shown one interesting exception to this tendency: Some men in dating relationships come to identify with the specific romantic relationship, which in turn promotes commitment. These men who began thinking in terms of "we" and in turn had high levels of commitment, increased their relationship illusions.

These studies suggest that commitment may motivate positive relationship processes and not just responses to threat. Consistent with this idea, commitment has been associated with building trust and the willingness to sacrifice personal goals for the good of the relationship. To date, relationship-enriching behaviors have been understudied by commitment researchers.

Despite the many ways commitment may contribute to relationship maintenance and growth, it is most critical in sustaining a relationship through challenges and adversities, be they daily hassles, major stressors, or boredom and complacency.

However, if commitment is carrying the relationship for long periods of time without satisfaction, there are likely negative consequences for both personal and relational well-being. Psychological constraints or fully immersed identities can keep a person in a destructive relationship. Processes that help maintain a relationship such as accommodation or forgiveness are agnostic about whether they are beneficial for the individual.

Loss of a Committed Relationship

Despite the numerous processes activated by commitment, relationship breakups occur sometimes despite earlier commitments. This may be because one or both partners became less committed or because the level of commitment was not sufficient to ward off a strong threat to the relationship. Generally, highly committed people experience increased psychological and even physical distress following the demise of an intimate relationship, likely because they have been abandoned by partners with weaker commitment. Given the epidemiological data on relationships and well-being, one may expect that the breakup of a relationship would result in distress. However, in the absence of high commitment, relationship termination is unlikely to have adverse consequences. On the other hand, when a relationship serves as a source of psychological meaning and reflects a personal identity, substantial psychological cost is likely after termination.

Although commitment is essential to relationship maintenance and relationship survival, how can individuals be certain that it is worthwhile to devote their energies to foster commitment? Part of the dilemma when faced with lower levels of negative behaviors or inadequately high levels of positive behavior is how to forecast a relationship future. Are these circumstances stable or unstable? Will the negativity subside or increase? Will the positive behaviors continue to wane or is this just a lull? Is one's partner committed, and does he or she genuinely care about oneself? A deliberative mind-set can help improve the accuracy of relationship forecasts, but deliberation is not without costs: Undue deliberation can paralyze an individual and prevent commitment and action. All relationships involve some degree of uncertainty and a

need for faith. Committing to a relationship is fraught with uncertainty and potential vulnerability. Pledging to devote oneself to a relationship and another person will affect one's life for better or for worse. More often than not, people are better off in relationships than alone, and people frequently recover and adjust following a failed relationship, so it may be worth the risk to commit.

COMMITMENT, THEORIES AND TYPOLOGIES

Commitment is a construct at the core of understanding human relationship maintenance. A number of commitment theories and typologies have been offered by social and behavioral scientists over the past several decades. This entry reviews some of these theories and typologies, emphasizing their points of similarity and their differences, and discusses why commitment plays a prominent role in research aimed at understanding the continuity of human relationships. The entry begins by reviewing how theorists have viewed the concept of commitment.

The Concept of Commitment

Commitment has been defined in various ways. At its root, commitment can be defined as intending to continue in a line of action. Thus, relationship commitment may be viewed as intending to continue in a relationship with a given person. The relative simplicity of this definition, however, masks significant differences in how commitment has been conceived by theorists over the years. Some view commitment in behavioral terms (i.e., continuing to do something). Others view it more psychologically, as the subjective experience of relationship continuation (e.g., how one feels about continuing a relationship with a partner). Some conceive of relationship commitment as a unidimensional concept, whereas others emphasize that it is either multidimensional in nature or that there are multiple types of commitment. For example, while some researchers describe commitment as having cognitive (e.g., thoughts), affective (e.g., feelings), and motivational (e.g., intentions) components, others describe several distinct types

of commitment itself (such as moral commitment, structural commitment, and personal commitment). Still others have emphasized the distinction between voluntary commitment (i.e., being committed because one wishes to be) and nonvoluntary commitment (i.e., being committed because one has to be). Although often possessing points of similarity, theories and typologies of commitment primarily tend to differ based on how commitment itself is conceptualized.

Theories and Typologies of Commitment

Early theories of commitment emphasized the positive factors that led people to continue in a relationship. Factors such as degree of love for a partner and satisfaction with the relationship were held to be important elements in keeping people together. Later theories, though not discounting the critical role of positive factors, included factors that prevent people from leaving a relationship, such as societal disapproval of divorce or not wanting to go through the process of starting over with a new partner. Currently, the most prominent extant theories of relationship commitment are George Levinger's Cohesiveness Theory, Caryl Rusbult's Investment Model, and Michael Johnson's tripartite typology. Although these approaches differ, they share some common elements, including the notion that relationships continue because of things that draw people to want to stay with a partner and because of things that prevent people from ending the relationship.

Levinger's Cohesiveness Theory of Commitment

Levinger was particularly interested in understanding processes involved in both keeping relationships (particularly marriages) together and breaking them apart. His Cohesiveness Model, rooted in Kurt Lewin's Field Theory, emphasized the role of two social forces in determining relationship commitment: attraction forces and barrier forces.

With respect to forces that attract, Levinger described two types of forces: present attractions and alternative attractions. Both present and alternative attractions are perceived as yielding

positive outcomes for the actor but are quite distinctive in nature. Present attractions refer to forces that draw a person toward continuing a given relationship. For example, the love one feels for a partner serves as a present attraction to the relationship and helps to sustain it. Similarly, need fulfillment, wealth, and status are all considered to be commitment-promoting attractions when they are present in a current relationship. Alternative attractions, in contrast, refer to forces that pull a person away from a current relationship. For instance, a particularly compelling unattached colleague for whom one feels attraction may serve as an alternative attraction.

Barrier forces are those things that keep partners from leaving their relationship. Levinger describes both internal and external barriers, each of which act to constrain a person from leaving a relationship. An example of an internal barrier is having feelings of obligation toward a partner, which might be rooted in a person's religious beliefs. Leaving a partner would breach the perceived obligation and generate negative feelings. In the case of a marital relationship involving offspring, feeling that children should be raised in a home with two parents may serve as an internal barrier to relationship dissolution. External barriers are forces that operate outside of the person. For example, stringent divorce laws that make it difficult to end a marriage would be considered an external barrier force that serves to maintain relationship commitment. Pressure from friends or family to "stick it out" and "make things work" also can serve as a potent external barrier to dissolution.

Together, attraction forces and barrier forces determine a person's commitment to a relational partner. As both types of forces are dynamic and subject to change over time, commitment may fluctuate.

Rusbult's Investment Model of Commitment

Rusbult's theory of commitment is rooted in Interdependence Theory, proposed by John Thibaut and Harold Kelley in the late 1950s. More specifically, Rusbult uses the interdependence concepts of dependence, comparison level, and comparison level for alternatives as a basis for

her Investment Model of Commitment. The Investment Model holds that commitment is the subjective experience of dependence and is a function of three independent variables: satisfaction level, quality of alternatives, and investment size.

The first variable held to influence commitment is satisfaction. Satisfaction level refers to the relative positivity of outcomes obtained in interactions with a partner. Outcomes are assessed with respect to a person's comparison level for similar outcomes within a given domain. For example, in determining whether one is satisfied with one's current romantic partner, one compares the outcomes received in interaction with the current partner to the outcomes that one has received in past similar kinds of relationships (e.g., outcomes from interactions with past romantic partners). If one's outcomes exceed those experienced in past relationships, one will be satisfied with the current relationship; if outcomes are below those experienced in the past, one will be dissatisfied with the current relationship. If a person has never had a past romantic relationship, he or she might compare the outcomes received in interactions with a new partner to outcomes that he or she has seen obtained by characters in a film or read about in a book. The main point is that past experiences serve to create expectations for a given domain of behavior (e.g., romantic relationships) that are used to evaluate how satisfied people are with newly obtained outcomes in that domain.

The second variable posited to influence commitment is alternatives. Broadly speaking, quality of alternatives refers to the satisfaction envisioned as attainable beyond the current relationship. For example, a person may consider a relationship with the next best available alternative romantic partner (perhaps an ex-partner or someone else to whom one is attracted). A person may also consider nonromantic alternatives to the current relationship, such as the satisfaction afforded by hanging out with friends or by simply being alone. The more compelling one's alternatives are viewed, the less committed one will be to the current partner. If alternatives are not perceived as particularly attractive, one will be more committed to the current partner.

The third factor referred to by Rusbult in her Investment Model is the model's namesake, investments. Sometimes people stay in a relationship

because they do not wish to incur the costs associated with a breakup. Investment size refers to those resources (both tangible and intangible) that one has put into a relationship that one would lose or have diminished in value if one were to leave the relationship. For example, a person may consider the time, effort, self-disclosures, joint friends, and personal reputation that might be lost or damaged upon ending a relationship. An interesting aspect of the investment concept is that it points to how a person may become committed to a relationship not because of positive feelings (i.e., satisfaction level) or a lack of other options (i.e., quality of alternative), but rather because a person may remain committed because he or she perceives that to do otherwise would yield unacceptably high costs. Thus, sometimes a person remains in a relationship even though that person really would rather not. An oft-cited illustration of this can be found in the conventional wisdom that marital partners sometimes remain together “for the sake of the children.” Indeed, children can be considered an investment that helps bind partners to their relationship.

Collectively, satisfaction level, quality of alternatives, and investment size are theorized to influence commitment level. A given relationship may be driven by one or more of these factors, and these factors have been found to work together in an additive fashion to influence commitment. Commitment level itself has been found to be associated with a number of relationship maintenance behaviors, such as willingness to sacrifice for one’s relationship and forgiveness of betrayal by one’s partner. Commitment level has also been found to mediate the effects of satisfaction level, quality of alternatives, and investment size on the enactment of such behaviors.

Johnson’s Tripartite Typology of Commitment

Johnson’s tripartite framework departs from the previous two models in conceptualizing commitment as a multidimensional rather than a unidimensional construct. Johnson specifies three distinct types of commitment: structural commitment, or feeling that one must remain in a relationship; moral commitment, or feeling that one ought to remain in a relationship; and personal

commitment, or feeling that one wants to remain in a relationship.

Structural commitment has four components: potential alternatives to the current relationship, perceived social pressure to remain with a current partner, irretrievable investments accrued over the course of a relationship, and the perceived difficulty of terminating the relationship. In Levinger’s terms, each of these components is held to make it difficult to end a relationship due largely to external constraints. Moral commitment is comprised of three components: the sense of moral obligation not to divorce one’s spouse, the sense of personal obligation to one’s partner, and the need to maintain consistency in one’s general values and specific beliefs. Personal commitment also has three components: overall attraction to a partner, attraction to the relationship itself, and one’s relational identity (i.e., the extent to which a person views the relationship as part of his or her self-concept).

There is clear overlap of many of these components with aspects of Levinger’s and Rusbult’s models. In contrast with Levinger and Rusbult, however, Johnson proposes that the three different types of commitment yield different subjective experiences. Each type is experienced as either originating from within the person or imposed from outside the person. Moreover, each type is experienced as a function of either choice or constraint. Structural commitment is based on factors that are external to the individual (e.g., social reactions) and is experienced as constraining the individual. Moral commitment is based on an individual’s own beliefs; but as morality is a function of societal beliefs, it is experienced as constraining. Personal commitment is based on an individual’s own wishes and desires and is, thus, experienced as freely chosen rather than as imposed.

Research by Johnson and colleagues has generally supported the tripartite typology. How do the three types of commitment work together to influence relationship continuation? Johnson proposes that when a person experiences strong moral and personal commitment, structural commitment is not needed to maintain a relationship. In contrast, if a person experiences low moral or personal commitment, structural commitment becomes paramount in determining relationship continuation.

Why Commitment Matters

Regardless of the theory or typology, commitment is considered an important variable by relationship researchers for several reasons. First, it is considered to be a key motivational variable, with powerful influence on relationship affect, cognition, and motivation. For example, research has found that people who self-report higher levels of commitment tend to think about their relationship in more partner-inclusive ways (e.g., they write about their relationship using more plural pronouns—we, us, our—and fewer singular pronouns—me, I, he, she), and they tend to see their relationship as better than others' relationships. Second, commitment has been shown to relate to the enactment of a variety of critical relationship maintenance behaviors. Behaviors such as accommodation, forgiveness, and willingness to sacrifice for one's partner help to sustain a relationship, keeping partners together through thick and thin. Put another way, people who are more committed to their partners act differently toward their partners than people who are less committed, and these actions contribute to relationship continuation. Third, commitment is a proximal predictor of relationship breakup. Over time, commitment ebbs for those people who eventually choose to terminate their relationship, and thus, commitment level serves as a potent bellwether for predicting the ultimate stability of a given relationship. Fourth, and finally, although romantic relationship commitment has been emphasized in this entry, the theories of commitment reviewed here can and have been used to understand commitment beyond the romantic realm. For example, commitments to a friendship, to an organization, to a sports team, or even to a policy position have all been examined using aspects of these theories. Thus, it appears that factors that lead people to continue in romantic relationships also play a prominent role in keeping them committed to a variety of pursuits.

COMMUNAL RELATIONSHIPS

In this entry, the nature of communal relationships is described along with behaviors characteristic of these relationships and the interpersonal skills needed to enact these behaviors. Defining communal relationship is simple: A relationship is

communal if at least one partner (and most often both partners) assumes responsibility for the other's welfare without expecting repayments for benefits given or feeling that benefits create debts. Recipients, likewise, do not feel indebted. Communal relationships are ubiquitous and are often (but not always) exemplified by romantic relationships, friendships, and family relationships.

Mutuality and Symmetry of Communal Relationships

Communal relationships are typically mutual with both persons willing to noncontingently benefit the other as need for and as opportunities to convey care arise. Communal relationships also are often symmetrical, with partners assuming equal responsibility for one another's welfare. However, even in mutual and symmetrical communal relationships, enacted responsiveness often will be uneven because needs themselves are often uneven. In well-functioning communal relationships, this is accepted.

Communal relationships can be one-sided in the sense that assumed responsibility for a relationship member's welfare goes only in one direction. That is, one person can assume communal responsibility for a partner who feels no particular responsibility for the other person. The parent of a child so severely handicapped that he or she does not even recognize the parent, for instance, might have a nonmutual, one-sided communal relationship with that child. More commonly, communal relationships are mutual but asymmetrical. Relationships between parents and adolescent children often fall into this category. The parent and child may each assume some responsibility for the other's welfare, but the parent assumes far more responsibility for the child than vice versa.

Distinguishing Communal From Exchange Relationships

Communal relationships were initially differentiated from exchange relationships in the late 1970s by Margaret Clark and Judson Mills. The distinction was a qualitative one based on differences in the norms governing the giving and receiving of benefits. In exchange relationships, benefits were said to be given contingently, with the expectation

of specific and timely repayments consisting of benefits of comparable value. In contrast, in communal relationships, benefits were given noncontingently on the basis of needs. Early research revealed that experimental manipulations increasing expectations and desire for friendships or romantic relationships also increased keeping track of a partner's needs, helping, responsiveness to a partner's expressions of emotion, and expectations that a partner would be responsive to one's own needs. At the same time, those manipulations also resulted in negative reactions to receiving repayments or requests for repayments and led to people avoiding keeping track of individual inputs into joint tasks for which there would be rewards.

A Quantitative Aspect of Communal Relationships

Shortly after proposing the qualitative distinction between communal and exchange relationships, Clark and Mills highlighted a quantitative dimension of communal relationships, *communal strength*. Communal strength refers to the degree of responsibility people assume for the partner's welfare and therefore, the effort and costs to which they will go to benefit that partner's welfare noncontingently. Most people have very weak communal relationships even with strangers. They meet small needs of strangers noncontingently by, for instance, telling the stranger the time with no expectation of repayment. On the other hand, most people have very strong communal relationships with their own children and go to enormous lengths in terms of time, money, and effort to benefit their children. Many communal relationships such as typical friendships fall in between these extremes in terms of strength. Along with the amount of support a person is willing to provide noncontingently to a partner, greater empathic compassion to a partner's plight or greater empathic joy in response another's good fortune serves as an indicator of the strength of a communal relationship.

Communal Relationships Are Not Always Unselfish Relationships

The distinction between communal and noncommunal relationships is not equivalent to a distinction

between unselfish and selfish relationships. A person can choose to form or maintain a communal relationship with a partner for selfish or unselfish reasons. For instance, one might provide an unpleasant elderly relative whom one does not like with communally given care because one feels a sense of duty to do so, would feel guilty for not doing so, and wishes to avoid criticism from outsiders. To give another example, a person may wish to form a new friendship in which he or she is noncontingently responsive to another person in part because this person hopes that the new friend will become communally responsive to him or her (but this person cannot require that as a condition for his or her responsiveness). Such motives include self-interest. Of course one can also experience empathy for another person and respond communally as a result. Such responsiveness is typically unselfish.

It is worth noting that a person also can follow an exchange norm for selfish or unselfish reasons. For instance, although people generally exchange money or goods for other benefits because they wish to have the benefit (a selfish motive), at times people insist on increasing a person's pay or giving them additional goods because doing otherwise would result in an unfair exchange and they truly do not wish, for unselfish reasons, for the other to be unfairly treated. Whereas the motive that drives one to adopt a communal (vs. an exchange) norm may be unselfish or selfish, once the communal norm is adopted, that norm dictates that benefits are provided noncontingently to promote the partner's welfare. It is the adoption of a communal norm for a particular relationship and adherence to that norm that defines a relationship as a communal one.

Contrasting Communal Relationships With Other Types of Relationships

Communal relationships can be contrasted not only with exchange relationships but also with other relationships. For example, noncommunal exploitative relationships also exist in which people wish to obtain as much from a partner as possible without providing the partner with anything of value. Exploitative relationships are truly selfish relationships.

Communal Relationships Can Be Short or Long Term

The distinction between communal and noncommunal relationships is not equivalent to a distinction between long- versus short-term relationships. One can have a very short-term communal relationship with a stranger, as when one provides help one time without expecting or asking for compensation, or very long term, as children and parents often have with one another. The length of communal relationships with friends or romantic partners typically fall in the middle of these extremes.

Organization of People's Sets of Communal Relationships

People's networks of communal relationships are organized hierarchically, and taken as a set, they typically fall in a triangular shape with the strongest communal relationships sitting at the top. At the bottom are the many weak communal relationships they have with many strangers and passing acquaintances, in the middle are a moderate number of communal relationships with people one might call friends, and at the top are a few very strong communal relationships, often with children, a spouse, romantic partner, parents, or a best friend. Responsibility for the self fits into this hierarchy as well, with people feeling more responsibility for the self than for many of those with whom they have communal relationships, but people sometimes feel equal or even more responsible for a particular partner or partners than they do for themselves. A person's hierarchy of communal relationships suggests whose needs will take precedence in the event of partner (and self) needs arising at the same time.

The Nature of Communal Responsiveness

Although early work on communal relationships emphasized the noncontingent provision of goods or services to partners, the nature of communal responsiveness encompasses a broad range of behaviors. When one assumes communal responsibility for another's welfare, that responsiveness may be enacted by providing concrete

help, providing emotional support, encouraging one's partner as he or she strives to reach a desired goal, restraining oneself from enacting behaviors that might harm the partner, including the partner in enjoyable activities, and providing the partner with symbolic signs of caring (as when a person sends cards, provides hugs, or simply makes statements indicating care such as, "I love you" or "I care about you").

Abilities Necessary to Act Communally

Successful enactment of a communal relationship entails two distinct sets of motivations and abilities: one set that facilitates providing of communal care to a partner and a second set that facilitates receiving communal care from a partner. These are intertwined motivations and skills.

To provide optimal communal responsiveness, one must be motivated to adopt the norm (e.g., through empathy or desire for an ongoing communal relationship) and then successfully enact that norm in interactions with the partner. This requires focusing on the partner and having the appropriate skills and fortitude to understand the partner, to accept the partner, and to provide care. Much research now indicates that having a chronic need to protect the self and an attendant chronic self-focus (meaning that one typically thinks of the self and the implications of the partner's behavior for the self without focusing on the partner or what one can do to support the partner) interferes with successful provision of communal responsiveness even when one wishes to provide it.

To receive optimal communal responsiveness from a partner over time, a person also must be comfortable with dependency on a partner. This entails a willingness to accept offered care, to ask for care, to self-disclose, and to acknowledge and express one's own emotions to the partner. Current research suggests that an inability or unwillingness to set aside worries about being vulnerable (and to reveal to others areas of low competence, sensitivity, and needs, generally) interferes with receiving communal responsiveness. Discomfort with accepting dependency can also result in inappropriate feelings of indebtedness and efforts to repay when a partner has provided benefits on a communal basis.

The Importance of Trust

In mutual communal relationships, high trust in partners facilitates the success of communal relationships, as it appears to be linked with the ability to flexibly shift one's focus of attention between the self and seeking help (when necessary), one's partner and providing help (when necessary), and engaging mutually enjoyable and beneficial joint activities (when own and partner needs are not pressing). Low trust in partners, in contrast, inhibits the ability of partners to form communal relationships by leading to chronic relational self-focus and self-protective tendencies. Low trust also leads to reluctance to give noncontingent help (lest it be rejected or lest the person be taken advantage of), to seek or accept help (lest it not be offered or create a sense of dependency or incompetence with which the person is uncomfortable), and to engage in mutually enjoyable activities (lest one's attempts be rejected, embarrass the self, or anger the partner).

Benefits of Having Communal Relationships

Mutual communal relationships, when functioning optimally, allow people to share responsibility for each other's welfare. Over time, they appear to be instrumental to maintaining and promoting mental and physical health.

COMMUNICATION, GENDER DIFFERENCES IN

Popular author John Gray created quite a stir when he published *Men Are From Mars, Women Are From Venus*, the first in what became a series of books on the differences between men and women. In these books, Gray cashed in on the persisting belief that men and women are fundamentally different—so much so that they come from different planets. Like many authors of popular books, Gray's work has little scientific basis. His claims of radical differences between the sexes are overstated and, in some cases, inaccurate.

This entry discusses gender differences in communication. The first section defines sex, gender, and communication and discusses relations among the three concepts. The second section discusses the processes by which individuals learn what society considers gender-appropriate behaviors, including communication. The final section identifies generalizable differences between women's and men's communication.

Definitions

Many people use the words *sex* and *gender* interchangeably, but actually they are discrete concepts. The distinction between sex and gender calls attention to the twin influences of biology and society—or nature and nurture—on our identities.

Sex

Sex is a biological category—male or female—that is determined genetically. Most individuals are designated as male or female based on external

genitalia (penis and testes in males, clitoris and vagina in females) and internal sex organs (ovaries and uterus in females, prostate gland in males). Genitalia and secondary sex markers such as hair growth and muscle mass are controlled by chromosomes and hormones. Most humans have 23 pairs of chromosomes, one of which determines sex. Although there are variations in sex chromosome patterns, typically, those people society labels male have XY sex chromosomes and those that society labels female have XX chromosomes.

Gender

Gender is a more complex concept than sex. In the 1970s, researchers began to draw a clear distinction between sex (male, female) and gender (masculine, feminine). They defined gender as a social construction in sharp contrast to sex as a biological phenomenon. Put another way, gender involves the social meanings attached to sex within a particular culture and in a particular era.

Because gender is central to social order, society works very hard to convince its members that its definitions and expectations of women and men are natural, normal, and right. From birth, most individuals are socialized into society's views of what it means to be a man or woman—what each sex should and should not do. Pervasive practices reflect and aim to reproduce social definitions of gender: pink and blue blankets, toys marketed to boys (active, adventure toys) and girls (dolls and play stoves), chores parents typically assign to sons (outdoor tasks) and daughters (indoor tasks), elementary teachers' tendencies to allow boys to play rougher and be less attentive than girls are expected to be, workplace norms that make it more acceptable for female than male workers to take parental leave.

It is important to realize that gender includes both femininity and masculinity. Gender is often perceived as a synonym for women or for women's interests. Just as the study of race is commonly, but mistakenly, perceived as not having anything to do with Caucasians, the study of gender is routinely perceived as having nothing to do with men and masculinity. However, Western culture recognizes two genders, and some other cultures recognize more than two. Masculinity is just as socially constructed as femininity, and understanding how and why masculinity has been constructed as it has

helps researchers understand how many men define themselves and which attitudes and behaviors they do and do not consider appropriate for themselves. Studying gender gives insight into the processes by which each (and all) genders are constructed and—by extension—the ways in which existing constructions of each (and all) genders might be challenged and changed.

Communication

Communication is a dynamic process of creating meaning through verbal and nonverbal symbols. Communication is a primary means by which new members of a society are taught existing views of gender. As parents interact with children, they teach gender. Boys may be discouraged from playing with dolls, and girls may be scolded for getting dirty—both messages convey social views of gender in an effort to teach children how to perform identities that are consistent with existing social norms.

Learning Gender

Parents, especially fathers, encourage in children what they perceive to be gender-appropriate behaviors, fostering more independence, competitiveness, and aggression in sons and more emotional expressiveness and gentleness in daughters. When interacting with children, fathers tend to talk more with daughters and to engage in activities more with sons. Mothers tend to talk more about emotions and relationships with daughters than with sons. Because both mothers and fathers tend to talk more intimately with daughters than sons, daughters generally develop greater relational awareness and larger emotional vocabularies than sons.

In general, parental gender socialization is more rigid for boys than for girls, particularly in Caucasian families, and fathers are more insistent on gender-stereotyped toys and activities, especially for sons, than are mothers. Fathers generally regard it as more acceptable for girls to play baseball or football than for boys to play house or cuddle dolls. Similarly, it is considered more suitable for girls to be strong than for boys to cry and more acceptable for girls to act independently than

for boys to need others. The overall pattern is that parents, especially fathers, more intensively and rigidly push sons to be masculine than they push daughters to be feminine.

Communication is not only a way that new members of a culture are taught gender but also the primary means individuals use to express gender. People know which clothes will be seen by others as masculine or feminine, which postures are regarded as appropriate and inappropriate for women and men, and which words and tones of voice are regarded as more acceptable for men and for women. In other words, individuals use verbal and nonverbal communication to “do gender.”

The related processes of learning about gender and learning how to communicate gender are highlighted in a classic study by Daniel Maltz and Ruth Borker. After observing young children at play, they drew three conclusions: (1) young children tended to play in sex-segregated groups, (2) groups of girls and groups of boys generally played different kinds of games, (3) the different games played by boys and girls teach subtly different styles of communicating. These observations have been confirmed by more recent research.

The games that boys typically play included football, baseball, basketball, and war, whereas the games that girls tended to play included school, house, and tea party. The games that boys typically play—ball, war, for example—involve fairly large groups—nine individuals for each baseball team, for instance. Most boys’ games are competitive, have clear goals (touchdown, basket, capturing the robbers or evading the cops), involve physically rough play (blocking linebackers, shooting robbers), and are organized by rules (nine innings to a baseball game, two points per basket) and roles (forwards shoot baskets, guards protect forwards) that specify who does what and how to play.

Because the games boys typically play are structured by goals, rules, and roles, there is limited need to discuss how to play, although there may be talk about strategies to reach goals. In playing games, boys learn to communicate to accomplish goals, compete for and maintain status, exert control over others, get attention, and stand out.

These understandings of how to use communication are consistent with other aspects of masculine socialization. For instance, these rules accent achievement—doing something, accomplishing a

goal. Boys learn they must do things to be valued members of the team. Also, consistent with masculine socialization to maintain control and not reveal emotions or weaknesses, typical boy games do not involve emotional disclosure or other types of intimate talk.

Quite different patterns exist in games typically played by girls—house, school, and tea party, for example—and they cultivate distinct ways of communicating. Girls tend to play in pairs or in very small groups rather than large ones. Also, games such as house and school do not have preset, clear-cut goals and roles. There is no touchdown in playing house, and the roles of daddy and mommy are not fixed like the roles of guard and forward. Because traditional girls' games are not highly structured by external goals and roles, players have to talk among themselves to decide what to do and what roles to play. Playing house, for instance, typically begins with a discussion about who is going to be the daddy and who is going to be the mommy. The lack of stipulated goals for the games is also important because it tends to cultivate girls' skills in interpersonal processes.

The typically small size of girls' play groups fosters cooperative discussion and an open-ended talking to organize activity, whereas the larger groups in which boys usually play encourage competition and external rules to structure activity. Research on preschoolers of different races shows that boys are more likely to give orders and commands, compete for status, and attempt to control others, whereas girls are more likely to make requests, cooperate with others, and use inclusive and nondirective language.

Gender Differences in Communication

The lessons of children's play, as well as parental instruction in gender, are carried forward. The basic rules of communication that many adult women and men employ are refined and elaborated versions of those learned in childhood.

Feminine Communication

Extensive research has identified seven features of feminine communication, which a majority of women employ. These features of feminine communication style are consistent with patterns of

interaction in games typically played by young girls. First, feminine communication involves disclosing personal information and learning about others. For many women, personal communication is a primary means of building close relationships.

Second, feminine communication attempts to create equality between people. Instead of vying for most valuable player status, women are more likely to communicate in ways that level the playing field. To create equality, women often offer matching experiences (e.g., "I've experienced the same thing") and work to include others and keep conversation balanced so that participation is relatively equal.

Third, feminine speech tends to offer substantial support for others. In conversations, women routinely express sympathy, empathy, and agreement with others (e.g., "Of course you feel hurt" and "I think you handled that really well"). In addition, women often communicate support by showing interest in learning more about others and their experiences (e.g., "How did you feel when that happened?").

A fourth feature of feminine communication is what Pamela Fishman, in a classic article, labeled *conversational maintenance work*. This is the process of keeping a conversation going by inviting others to speak, asking questions to draw others into interaction, responding to what others say, and encouraging others to elaborate their ideas. Rather than working to get and hold the talk stage for themselves, those employing a feminine communication style emphasize getting everyone on the talk stage.

Fifth, feminine communication tends to be highly responsive, especially nonverbally. Women exceed men in eye contact during conversations, head nodding, and facial expressions that show interest as well as verbal responses that demonstrate engagement in others and what they are communicating.

Sixth, feminine communication tends to be somewhat more concrete than masculine communication. Women typically include details when describing events and experiences and provide specific examples to illustrate ideas. In addition, women tend to cite personal experiences as bases for broad judgments and values.

Finally, feminine communication tends to be more tentative than masculine communication. Women are more likely to use hedges (e.g., "I sort of think that plan is dangerous"), qualifiers (e.g., "I

don't have much experience with this issue, but . . ."), and tag questions (e.g., "The weather is really nice, isn't it?"). Although the tentativeness of feminine communication has been criticized for being unassertive and powerless, it is also inclusive, opening the door for others to enter conversation.

Masculine Communication

Researchers have identified six features of masculine communication, which is favored by a majority of men. These features are consistent with socialization provided in games that young boys typically play. The first feature of masculine communication is control, or the effort to control. Many men see interaction as an arena for pitting themselves against others and for proving their worth. The effort to control is displayed by asserting opinions, challenging others, and telling stories and jokes that capture others' attention.

A second feature of masculine communication is instrumentality, which is accomplishing objectives. In interaction, instrumentality is expressed through problem solving (e.g., "We need to figure out how this program works before we can revise it"), giving advice (e.g., "What you should do is . . ."), devising strategies (e.g., "Here's a way to outflank the other team"). In contrast to the feminine attention to feelings and process, masculine style puts greater emphasis on facts, tactical plans, and results.

Third, masculine communication tends to be dominant. Although there are many jokes about women's talkativeness, it is actually men who talk more in most contexts. Research by Mary Crawford and Michele Kaufman demonstrates that men talk more often and for longer periods of time than women in multiple contexts, including classrooms, business meetings, and informal conversations. In addition, men are more likely than women to reroute conversations to their interests and agendas (e.g., "What you're saying about the problem with your coworker reminds me of a time when I had to work with a real jerk . . .") and to interrupt others to maintain conversational dominance.

Fourth, masculine communication tends to be direct and assertive. In contrast to the tentativeness of feminine communication, the masculine style tends to be more forceful, unqualified, authoritative, and commanding (e.g., "Do it this way" and "The best approach is . . .").

Fifth, masculine communication is more abstract than feminine communication. Men rely less than women do on concrete examples, specific experiences, and concrete reasoning. Instead, men often talk at abstract levels, relying on generalizations and conceptual levels of description (e.g., "Higher order questions are more intellectually stimulating").

A final feature of masculine communication is restricted emotionality. In general, men's speech is less emotionally disclosive and responsive than women's. They are less likely than women to express sympathy, empathy, or other feelings in response to what others say. For example, masculine style would favor responding to another's disclosure with a statement such as "I understand," whereas feminine style would favor responding with a statement such as "That's so sad—you must feel really bad."

Anthony Mulac recently studied women's and men's language to see whether differences noted in earlier research still exist. He concluded that women and men have subtly different communication styles. Mulac identified six distinctive characteristics of men's language use and 10 distinctive characteristics of women's language. The differences are listed below:

More Prominent in Males' Communication

1. References to quantity ("50 percent of the time")
2. Judgmental adjectives ("boring discussion")
3. Elliptical sentences ("Good job")
4. Directives ("Work on it")
5. Locatives (location markers) ("The house faces north, northwest")
6. I-references ("I have a busy schedule")

More Prominent in Females' Communication

1. Intensive adverbs ("That's really exciting")
2. Emotion-references ("I know he loves me")
3. Dependent clauses ("I am majoring in communication, which is a very dynamic field")
4. Sentence-initial adverbs ("When I stay up late, I feel terrible the next day")

5. Uncertainty verbs (“It might happen”)
6. Oppositions (“The teacher is demanding, yet she is also fair”)
7. Negations (“Speaking up in class will not make you sound like a nerd”)
8. Hedges (“I’m sort of thinking we should stay in tonight”)
9. Questions
10. Longer sentences

Qualifying Research Findings

The forgoing research findings should be qualified in three ways. First, research provides generalizations about how women, in general, and men, in general, communicate in a specific cultural context. It cannot predict how any particular individual will communicate. Some men communicate in primarily feminine ways, and some women communicate in primarily masculine ways. Further, most people—regardless of sex and gender—engage in some masculine and some feminine communication behaviors. Very few people communicate in solely masculine or solely feminine ways. Second, the findings are better understood as fitting on continua than as being dichotomous—for instance, in general women talk more about emotions than men, yet men also talk about emotions. Third, the findings do not describe all tendencies in either feminine or masculine communication styles. For example, there has been more research on inclusive and supportive interaction than on competitive, “catty” exchanges between women, so researchers know less about the latter. Finally, what is considered masculine and feminine varies across cultures and times, so what is regarded as masculine communication in the West in 2010 might be viewed as feminine in another culture or time.

COMMUNICATION, INSTANT MESSAGING AND OTHER NEW MEDIA

Communication is necessary to develop, maintain, and end relationships. Today, a portion of that relational communication for many people, particularly adolescents and young adults, occurs in text-based modalities that can be sent instantaneously but do not require physical presence with the other. The main forms of instantaneous text-based communication at a distance are e-mail, instant messaging (IM), mobile phone text-messaging, and messages sent through social network sites such as *MySpace* and *Facebook*. This entry begins by comparing text-based forms of communication with other forms of communication. Then, this entry discusses how these forms of

communication are used to initiate, maintain, and in some cases, end relationships.

Text-Based Messages Compared to Other Forms of Communication

Text-based communication, regardless of the specific modality, has been compared to other forms of communication but particularly to face-to-face communication and voice communication over the phone. Relative to these other forms of communication, text-based communication (a) allows one to take time to communicate, including editing responses; (b) gives the flexibility to communicate without being interrupted by the other; (c) can be asynchronous, which means that two people with different temporal schedules can still easily communicate; (d) presents the opportunity for the same message to be sent to several people simultaneously; and (e) allows for—and in many cases, requires—brief messages. Text-based communication also represents an economical way to communicate; for example, there is no need to pay the expense of transportation to meet for face-to-face conversation. However, relative to face-to-face and voice communications, text-based communication has lower social presence and reduced social cues. That is, the other is less “present” in the interaction, and therefore, there are fewer cues as to the other person’s characteristics and emotional reactions. Messages that require nonverbal cues for interpretation, such as sarcasm, can lead to misunderstandings. To compensate, various paralinguages (e.g., emoticons) have been developed. Another disadvantage of text-based communication is that less information can be transmitted in the same amount of time because vocal speech is faster than the process of writing text messages on a computer or mobile phone. In addition, text-based messages, particularly when there is anonymity, can lead to disinhibition in behavior including flaming. This behavior involves writing negative comments and interpersonal attacks and can occur in any text-based medium.

There are also distinctions among the modalities of text-based communications. For example, instant messaging and mobile phone texting tend to be more interactive, informal, and synchronous than e-mail. Mobile texting, a function on cell

phones similar to messages sent through the Internet, is limited to brief messages because of (a) bandwidth limitations of cell phone carriers and (b) the limitations of the inputting text on a traditional telephone keypad (many new cell phone models, however, offer miniature keyboards to aid in mobile messaging). Unlike the other modalities, social network sites generally have two forms of text messaging: traditional site-specific person-to-person messaging and a comment board. Although anyone can send a private personal message to another user, comment boards are designed to be publicly viewed, but only approved users have posting rights. Although e-mail is now used by people of almost all ages, the other forms of text-based communication technologies are used primarily by teenagers and young adults.

The Role of Text-Based Messages in Initiating Relationships

A small but growing percent of romantic relationships and friendships begin online. These relationships may begin in a chat room, in a multiuser Internet game, at a social network site (e.g., *Facebook*), or through a dating site (e.g., *PerfectMatch.com*). For example, a recent study with teenagers indicated that approximately one half reported using social networks to initiate new friendships. Research conducted with individuals in Internet newgroups has found that a majority of those sampled report that they have developed a friendship or romantic relationship with someone they met through this online venue. Although marriages and other committed relationships are still more likely to have their origin in traditional settings, a recent nationwide study conducted by Harris Interactive found that 3 percent of their respondents reported having met their current partner through an online dating service, and another 3 percent met in an online chat room.

Regardless of the specific online way in which two people first become aware of each other, text-based communication is generally the modality for first communication. For example, two people who meet through an online dating service first use text-based messages often sent anonymously through the dating site for the purpose of determining their compatibility. People who meet in

other online ways (e.g., chat rooms, social network sites) usually begin with more informal messages, perhaps focused on the shared hobby or friend.

People may also initiate a relationship with someone through text messages (e.g., e-mail) after meeting in person, such as at a party or a professional meeting. Whereas people used to exchange phone numbers upon meeting for the first time, today it is just as common to exchange e-mail addresses or user names.

Factors that lead to initial attraction through text-based communication may differ from factors that lead to attraction in face-to-face settings. Much has been written about the ease of self-disclosing through text-based messages and the important role of text-based self-disclosure in leading to attraction. Experimental studies conducted by Katelyn McKenna revealed that undergraduate students who met for the first time through text-based messages in an Internet chat room liked each other more than those who met for the first time face-to-face. The self-disclosure can be rich and allow the relationship to progress quickly. It has been speculated that physical attractiveness, which is often the characteristic people notice first about someone in a face-to-face setting, has less impact when initiating a relationship through text-based communication because its salience is likely to follow learning other information about each other. Another unique factor found to affect attraction through text-based communication technologies is writing skill. Those who write well are perceived more positively.

A dark side to relationship initiation through text-based communication is that it may be easier to engage in deception. In addition, idealization of the other can occur, which includes idealistic forecasts of attractiveness of the other, perceived similarity between self and other, and the potential for compatibility. This idealization can lead to disappointment when meeting in person.

The Role of Text-Based Messages in Maintaining Relationships

When the Internet first gained widespread use, there was concern about its effect on relationships with friends, relatives, and neighbors. The concern was that the time spent writing text messages to distant others would take time away from significant core

relationships. However, the effect of the Internet seems to be more positive than negative for maintaining relationships, according to research conducted by the Pew Internet and American Life Project, which monitors the role of the Internet in Americans' lives. E-mail is especially useful to maintain ties with friends and relatives who live at a distance. In addition, relationships with geographically close friends and relatives can be enhanced by e-mail and other forms of text-based communication. In many cases, text messages do not reduce other forms of communication for maintaining local, close relationships but may actually increase it, which has been called *media multiplexity* or *mixed-mode relationships*. Some relationships remain online and need online communication for their maintenance. Generally, however, such relationships either eventually end or progress to a face-to-face meeting.

The Role of Text-Based Messages in Ending Relationships

Telecommunication technologies have been used not only to develop and enhance relationships but also to end relationships. According to the Pew Internet and American Life project, 9 percent of single adults have broken up with someone using online communication. Teens are probably more likely than adults to terminate relationships online. Although breaking up through text-based communication may be becoming more common, people perceive it to be a noncaring way to end a relationship, according to recent research. Relationships that form over the Internet may be especially prone to early and easy termination, possibly because alternatives are perceived to be plentiful and only a click away.

COMMUNICATION, NONVERBAL

Nonverbal communication, also sometimes known as body language, encompasses the various ways people communicate without language. Although verbal, linguistic communication is a unique and vital part of human communication, considerable meaning is communicated nonverbally. Though estimates vary, most communication and relationships researchers agree that nonverbal communication is every bit as important as or more important than verbal communication, particularly in human relationships. The relative significance of verbal and nonverbal communication is not important. What is important is that extensive research shows that the various aspects of nonverbal communication—eye behavior, touch, body movements, interpersonal distance, facial expressions, and all the other components of nonverbal communication, separately or together—are vitally important to human relationships. This entry discusses how nonverbal communication differs from language, the biological foundation of nonverbal communication, and its multichanneled nature including physical appearance, body language, eye behavior, interpersonal distance, touch, vocal characteristics, the use of time, and the environmental context in which communication occurs. It concludes with a comment regarding the centrality of nonverbal behavior in close relationships.

Nonverbal communication encompasses all communication other than language. Nonverbal communication is analogic, iconic, and does not rely on symbols, in contrast to language that employs symbols that are arbitrarily related to their referent. Substantial research suggests that verbal and nonverbal communication employ different cognitive systems. Typically, nonverbal

communication is processed in the right brain hemisphere rather than in the language centers of the left brain hemisphere.

Nonverbal communication is primarily analogic, meaning that nonverbal messages have a more direct relationship with their referent compared with verbal or linguistic messages that are arbitrarily related to their references. Generally, nonverbal messages feel, look, or sound like what the things they refer to or represent; for example, a pat on the back is an abbreviated hug and standing closer represents more relational closeness than standing far away. Analogic messages are usually a matter of degree as opposed to a digital on-off message. A hug can range from brief and obligatory, to moderately warm and affectionate, to prolonged and passionate. Smiles can run the gamut from smirks, to grins, to broad beaming smiles. Interestingly, because iconic and analogic communication are continuous, people cannot stop sending relational messages nonverbally. There is no neutral facial expression or nondistance between two people. Thus, as long as two people are in each other's presence, relational communication is occurring via nonverbal communication. This leads to the famous communication axiom, one cannot not communicate.

Nonverbal communication employs a variety of channels, all of which are nonlinguistic. Most gestures are nonlinguistic, but sign language and emblems, which are gestures with dictionary definitions (e.g., the okay sign), constitute gestural languages that are processed in the same left hemispheric brain centers as speaking or writing. Tactile communication is usually nonlinguistic and nonverbal, though Braille print is read tactilely; it is a linguistic form of communication. Tone of voice and nonlinguistic vocalizations such as grunts or screams are nonverbal, but the spoken word is verbal. The mode is not the key to understanding nonverbal communication. The key is that nonverbal communication is nonlinguistic, is not arbitrarily related to its referent, and is not dependent on the language centers of the left brain hemisphere, unlike verbal communication.

Biological Basis of Nonverbal Communication

Nonverbal communication is a more biologically based system that evolved considerably earlier in

the history of the human species than did verbal communication. Virtually all animals relate to each other through the primary system of nonverbal communication. Verbal communication developed from the more ancient nonverbal means of communicating, which may be the reason that touch, facial expressions, and the many channels of nonverbal communication have an authenticity that words lack. By contrast to nonverbal communication, verbal communication, which is based upon and developed from the earlier nonverbal system, is a comparatively recent accomplishment in the human species.

Similarly, nonverbal communication occurs earlier in human development than verbal communication. Babies are proficient in nonverbal communication, sending and receiving messages through touch, vocalizations, eye behavior, and facial expressions. Speaking and writing must await additional chronological and cognitive development. The primary nature of nonverbal communication may be another reason why nonverbal communication seems more authentic in human relationships than words. It is more basic, fundamental, less controllable, and harder to fake than verbal utterances.

The biological basis of nonverbal communication makes it more understandable across cultures. Friendly touches, warm smiles, or closer distances tend to send positive affect among communicators even when they do not speak the same language. Verbal communication is virtually impossible among people who do not speak the same language. The biological basis is particularly evident for facial expressions that successfully communicate basic emotions like happiness, sadness, surprise, fear, anger, and disgust across culture. Slight differences in the expressions exist between cultures akin to regional accents in English in the United States. Although there are many cultural differences in nonverbal communication, these intercultural variations are much less pronounced than for verbal communication.

Channels of Nonverbal Communication

Nonverbal communication is the most basic, important, and authentic form of communication for another reason; nonverbal communication is

multichanneled, whereas verbal communication is single channeled. For instance, people express affection for one another via facial expression, distance, touch, body position, eye behavior, and warm vocal inflection. These multichannel messages are much harder to fake than a verbal utterance. It is difficult to pull off a multichanneled lie, so nonverbal communication is justifiably perceived as more genuine. The nonverbal channels discussed below are individually and collectively powerful determinants of human relationships.

Physical appearance. Long before words are uttered, relationships are determined by the physical appearance of another person. Physical attractiveness, body type, clothing style, race, biological sex, age, ethnicity, and height constitute powerful nonverbal messages that create initial impressions and determine the course of relationships. Appropriately or inappropriately people employ physical appearance cues to make attributions about other people's friendliness, warmth, attractiveness, intelligence, moral character, personality, and social status. Even once a relationship is established physically, appearance cues determine interactants' ongoing attraction and perceptions about another person's character, competence, and social appropriateness.

Kinesics. The study of the many ways that bodily actions, facial expressions, head positions, gestures, interactional synchrony, and sitting, walking, or standing positions constitutes kinesics. Facial expressions are a prominent and primary means of emotional expression and are vital to the coordination of interaction, which in turn facilitates or hinders human relationships. The basic human facial expressions are thought by most researchers to be innate, including fear, happiness, anger, surprise, sadness, and disgust, but their expression is controlled and managed by learned cultural display rules. Human gestural communication coordinates interpersonal interaction and provides emphasis, direction, illustration, and communicative redundancy. Body movements of the torso and legs reveal cues regarding gender, culture, age, agility, dominance, and personality.

Oculesics. The study of human visual interaction is called oculesics. The most important oculesic cue

in human relationships is eye contact, sometimes called mutual gaze. Eye contact is an invitation to communicate in initial interaction and a crucial communication channel in close relationships. Eye contact can also regulate communication, increase immediacy, monitor ongoing interaction, intimidate, promote flirtation, provide turn-taking cues, signal attentiveness, increase warmth, and perhaps most importantly, express involvement and intimacy. Pupil dilation is an important subliminal cue that sends messages of warmth, affection, and interest to receivers. Eye movements and blinking are signs of cognitive activity to which receivers attribute considerable relational meaning. Gaze direction also sends relational messages of attentiveness or disinterest and degrees of conversational involvement.

Proxemics. Personal space, territoriality, and crowding are proxemic variables that are vital in human interaction. Personal space, the invisible zone the surrounds people's bodies, is both an interpersonal message and an indicant of relationship closeness. Research has shown that relatively closer personal space distances, inside 1.5 feet in North America, indicate an intimate relationship. Of course, cultures vary and contact cultures that are centered in the Mediterranean region and generally found closer to the equator exhibit much closer interpersonal distances than cultures in the far north. Territoriality, possession of a fixed or home space, is evident in most species including humans. Like other animals, people protect and defend their home space against uninvited intrusion to promote safety and preserve resources. Sharing territory such as a home, an office, or a car is indicative of relational closeness. Finally, crowding is typically a negative proxemic cue that causes stress and discomfort. However, some events like discos, sporting events, and parades are expected to be crowded, adding to the excitement and positive arousal associated with the event.

Haptics. Among the most involving, intimate, nonverbal behaviors, haptic or tactile communication can be the source of intimacy, passion, or revulsion. Haptic communication is vital for infants, serving as a source of comfort, reward, and connection from the earliest days following birth.

Tactile deprivation in infancy is associated with numerous physical, psychological, and cognitive pathologies in later life. For adults, appropriate, affectionate touch conveys feeling of warmth, immediacy, intimacy, connection, informality, and closeness. Touch increases compliance with interpersonal requests and acts as a reinforcer of previous behavior. Research has shown that people who have negative attitudes toward touch and avoid interpersonal touch have less satisfying close relationships than people who approach and enjoy touch. Romantic couples touch least early in their dating relationships and most in intermediate relational stages when they are regular dating partners, engaged, or newlyweds. Long-term married couples, even very happy ones, touch less as their relationship matures. Additionally, couples converge over time, manifesting more similar levels of tactile interaction the longer the relationship has been in existence. Touch can be loathed as well as liked. If touch is harassing, excessive, or relationally inappropriate, it will lead to relational disengagement and even legal action.

Paralanguage. Paralinguistic or vocalic communication is vocalized nonverbal information. Some vocalic cues, such as sighs, groans, cries, inhalations, and yawns, stand alone, but vocalic information accompanies all spoken communication. Depending on how it is said, a word such as *okay* can communicate agreement, affirmation, hostility, eagerness, dismissiveness, reluctance, confusion, intimacy, boredom, seduction, affection, impatience, and many other messages. Vocalic cues such as pitch, cadence, speed, resonance, control, and accent lend meaning to every spoken word.

Paralinguistic cues are essential in the communication of intimacy; indeed, they may be more important than what is actually said in signaling closeness and connection.

Chronemics. The way people utilize time and the meanings that attach to time in interpersonal relationships is called chronemics. In America and most of the developed world, time is viewed as a commodity, so amount of time spent with another person indicates their importance and signifies closeness. Studies suggest that one of the most powerful predictors of relational satisfaction, closeness, and understanding is time spent together.

Sharing of talk time is associated with more relational satisfaction; likewise being on time is a courtesy that is associated with greater relational satisfaction. Studies suggest the timing or matching of interaction patterns is indicative of relational rapport and closeness.

Interpersonal environments. The environment in which relational communication takes place has a profound effect on human relationships. Many environments facilitate intimacy such as a cozy table at a restaurant, a hot tub, or a couch by a fireplace. Environments that facilitate work relationships include round tables, bright lights, cool temperatures, the absence of distractions, and good acoustics free of noise. All human interactions are facilitated by face-to-face arrangements, close distances, and eye contact. Human microenvironments are message systems in and of themselves that suggest the nature of the relationships and activities that are likely to take place.

The Centrality of Nonverbal Communication in Relationships

Nonverbal messages are at the heart of relational communication. Though verbal communication is clearly superior for detail, analysis, and precision, nonverbal communication is the primary way people communicate emotion and send interpersonal messages about the relationship. Positive affect, a primary building block of all relationships, is communicated via the multidimensional, implicit nonverbal communication system. Nonverbal communication in all its forms is at the heart of intimacy, closeness, connection, and rapport that characterize the apex of human relationships.

COMMUNICATION, NORMS AND RULES

The terms *rules* and *norms* are often used interchangeably. Some scholars argue that the two are synonyms. Others consider rules and norms as distinct. In this entry, largely following principles suggested by Susan Shiminoff, definitions of and distinctions between communication rules and norms are made and some classic communicative examples are offered. In addition, constructs similar to rules and norms, often used to mean rules or norms, including maxims, principles, and expectations, are discussed, as are the associations among these constructs.

Norms and rules run the gamut from microlevel (e.g., rules of grammar) to macrolevel (normative rules for international negotiations), and only very communicative rules and norms are presented in this entry. Consideration of rules and norms are important to relational scholars, as rules, norms, and expectancies often describe or prescribe the manner in which people interact or believe others interact. However, the terminology (and the actual constructs studied using these terms) is far from uniform.

Rules

Whether implicit or explicit, rules are generally thought to have three characteristics: (1) They are followable; one can choose to follow, or not to

follow, rules. They are not like laws of gravity wherein one has no choice but to adhere. (2) Rules are prescriptive; a certain behavior is expected or preferred (in a particular context). Behavior that should not occur is also prescribed. Not following rules is subject to sanctions. (3) Rules are contextual; the prescribed behavior must be applicable in similar contexts. Rules vary in the number of situations to which they apply. A broad or high-level rule applies to many situations. More narrow rules cover fewer contexts. These three characteristics have embedded within them the idea of behavior. Behavior is often considered as a fourth characteristic of rules: Rules reference behavior (not attitudes, opinions, thoughts, and the like).

The most prominent study of conversational rules can be found in the work of Harvey Sacks, Emanuel Schegloff, and Gail Jefferson. Among numerous rules of conversing, largely concerning the sequencing of conversations, they identify rules governing turn taking in everyday conversations. A primary rule is that one party should talk at a time. This rather broad rule may cover many instances. In everyday conversation, four turn-taking rules have been identified: (1) If the speaker selects the next speaker to take a turn, that target is obliged to take that turn, and others are obliged to allow the selected target to take the turn. (2) If the above occurs, the current speaker is to enable a transition to occur (i.e., provide a turn-relevant place). (3) If the current speaker does not select the next speaker, self-selection may be invoked at the next turn-relevant place. (4) At any turn-relevant place, the current speaker may stop but does not have to stop unless that speaker has selected someone else, or someone else has self-selected to take a turn. These rules apply to everyday conversations but do not necessarily apply in institutional talk wherein changes in rules can occur quite frequently (e.g., the rules of debate). Note, however, that even in debate, the broader rule that one person should talk at a time still applies. Further, violations of these rules are generally met with displeasure. That is, what should not occur is implicit: One should not interrupt the current speaker.

Norms

Many consider rules and norms as synonymous. By some definitions they are. If one defines norms

as shared expectations, the violation of which is met with sanctions, then norms and rules are the same. It is useful, however, to consider a norm as a statistical concept: It is the average or modal behavior. Norms are not necessarily what should be done or what is perceived as being done. Rather, they describe what is. Rules of grammar versus the norms of grammar usage exemplify this difference. In standard English, the formal medium of written expression, there are numerous complex rules, one of which is that a sentence should not end with a preposition. However, in everyday talk, it is normative to end sentences with prepositions. The grammatical rule is not the grammatical norm. Or, referring to the turn-taking rules, not to interrupt is the rule, but interpretations might be the norm.

Normative Rules

Using the definitions outlined above, one can identify instances wherein rules do prescribe normative behavior. Such instances have been labeled *normative rules* or *injunctive norms*. As noted, what actually occurs (is normative) is often what is prescribed (a rule). Erving Goffman's lifetime body of work identifies many such normative rules of communication process and practices that comprise the interaction order. He identified and explicated normative social behavior in everyday life and institutional behavior. Goffman also discerned normative rules as the means individuals use to strive to maintain or become part of a particular group or society. He observed stigmatized individuals, noting that such individuals may be the most aware of social norms, as they can more readily see the discrepancy between how they are treated compared to those who are not stigmatized. Goffman discusses individuals' attempts to act and appear normatively in order to present themselves as fitting into society.

Goffman is well known for the concepts of face and face-work. Among other goals of an interaction (part of the interaction order), individuals cooperate or work together to maintain face of the individuals involved, at least for the moment, as losing face results in embarrassment or humiliation for one or both parties. Thus, any given society has developed complex ways for individuals to

cooperate to maintain (or restore) face. Someone might pretend not noticing an error on another's part. Or a person might offer an acceptable excuse for one's own or other's behavior. Though certainly people do not always work to maintain each other's face, the normative rule in everyday social interaction is to do so.

Normative influence occurs when the perceptions of norms guide behavior. Goffman studied normative rules in observing and describing how individuals strive to be seen in a normative light. When desiring to be normative, individuals can only behave in the manner that they perceive to be normative, which might or might not be the actual norm. Harold Garfinkle played a major role in understanding the strength of normative rules through his observations of violations of these rules. His work involved the purposeful violation of normative rules. To Garfinkle, the strength of a normative rule is indexed by the severity of the reaction to the violation of that rule.

Maxims and Principles

Many have considered both maxims and rules as conversational principles. However, Joan Ganz argued that principles, though prescriptive and thus rule-like, are highly abstract. The notion of communication values offers a fair description of principles, perhaps akin to a code of ethics. The most widely known conversational principle is that of cooperation. H. Paul Grice offered the cooperative principle conveying the idea that conversational participants should work together during the course of a conversation. Speakers offer utterances with the intent that listeners will attempt to infer and understand, whereas listeners assume that speakers are speaking in a manner to facilitate such understanding. As Robert Nofsinger noted, individuals who work together to make conversations make sense. Maxims similarly can be considered rules, as both prescribe preferred behavior.

Grice provided four maxims or guidelines for achieving the cooperative principle. These maxims are abbreviated as quantity, quality, manner, and relevance. The maxim of quantity directs one to offer the appropriate amount of contribution to a conversation: Do not say too much; do not say too

little. Quality reminds people to be truthful, saying neither what they know to be false nor what they lack evidence of truth. Relevance means making conversational offerings related to the interaction at hand. Manner translates roughly into avoiding obscurity, equivocation, or ambiguity, to be clear.

Violations of one or more of these maxims are sometimes required in order to follow the cooperative principle. The value of equivocal messages has been shown in the work of Janet Beavin Bavelas. Recognizing that people often have multiple goals, sometimes one maxim must be violated in order to uphold another. For example, in order to be polite, it is often necessary to be vague and less than entirely truthful. Joking and other social behaviors may demand (acceptably) violating one or more of these maxims to achieve the desired purpose of being humorous.

Joan Ganz proposes that the distinction between rules, maxims, and principles is one of the levels of abstraction. Rules, maxims, and principles might be thought of as nested. A general principle is to be cooperative. This might be accomplished through the use of the Gricean maxims. Yet these maxims must be broken down into specific prescribed behaviors or rules. When someone says thank you, the general principle of cooperation, and Gricean maxims, do not tell one what to do. The rule prescribing uttering "you're welcome" does. After a relative gives a young child a gift, a parent might say to the child, "Now what do you say?" A child might offer all of the polite words in her or his repertoire: "please," "thank you," and "I'm sorry." These constitute the words the child knows to say after an authority figure says, "Now what do you say?" The principle of cooperation is certainly in play, as are all four maxims. However, precise rules surrounding which polite word is said in what situation have yet to be learned.

Expectations

Relational scholars often concern themselves with whether or not expectations are met. It is proposed here that expectations are most usefully considered at the individual level. Expectations are not necessarily rules or norms, though they are often treated as such. Individuals' expectations are formed from influences, possibly including rules

and norms. Whatever their origin, people have beliefs, standards, or expectations of what relationships and communications should be like. This concept has sometimes been called having implicit theories of relationships (among other terms).

Expectations, which are learned and modifiable, reference beliefs about the likely or desired behavior of others. To illustrate, examples of normative behavior in relationships can be considered. Michael Argyle and Monica Henderson offered six rules as the most important rules of friendship, the violation of which were most likely to result in the demise of a friendship: (1) standing up for the other in his or her absence, (2) sharing news of success with him or her, (3) showing emotional support, (4) trusting and confiding in each other, (5) volunteering to help in time of need, and (6) striving to make him or her happy while in each other's company. Yet one could have a particular friend who repeatedly violates one of these societal norms. Friends may hold these general expectations about friendships but have different expectations based on past behavior of that particular friend.

In sum, the subtle distinctions among norms and rules are important for scholars striving to better understand everyday interaction. Most individuals in a given society do not consciously differentiate among these terms, but most are at least implicitly aware of the norms and rules of their society.

COMMUNICATION ACCOMMODATION THEORY

Formulated by Howard Giles in the early 1970s (and refined with colleagues across different disciplines over the years), Communication Accommodation Theory (CAT) attends to a fundamental dimension of human relationships, namely how people adjust their communication patterns vis-à-vis each other. More specifically, CAT lays out the conditions under which individuals will, to varying degrees, wish to reduce or emphasize the social distance between those with whom they are interacting (i.e., by accommodating or nonaccommodating, respectively). Although the theory indicates different ways of achieving these ends, converging toward or diverging away from another have been the major ones studied. CAT also attends to the social consequences, immediate as well as long term, for such convergent and divergent tactics. In what follows, the major reasons for and the outcomes of such accommodative acts are overviewed.

Accommodating or converging toward another can occur at numerous levels. Making a coffee that satisfies the known tastes of another (e.g., dark brown or very milky) would be an example, as would using cosmetics or dressing up to match someone's idiosyncratic preferences in fashion when going out together. Most research, however, has been devoted to the verbal and nonverbal parameters of communication, such as expressing opinions that are meant to approximate the political positions of others or laughing at their supposed humor. Although such acts can be consciously enacted and can require constant monitoring with

subsequent adjustments, they can also emerge without much awareness, as is often the case in subtly shifting toward another's accent, posture, speech rate, voice quality, discursive style, and so forth. Mutual accommodations can engender a growing and positive relational identity—as it can among different aged (as well as socially disparate) relatives with respect to a strong sense of family identity.

The theory proposes that people converge toward or accommodate the communicative patterns of others the more they desire their approval, respect, cooperation, and compliance. Social power, thereby, figures prominently in CAT; organizational subordinates converge more to superordinates than vice versa, traditional females to males more than the converse, and so forth. Hence, tourists adopting the language, or even key words (e.g., “hello” or “thanks”), of their hosts' language, is known—certain caveats notwithstanding—to elicit favorable reactions in and valued support from many locals. In other words, accommodation is positively perceived and can even be socially effective beyond the single act; those who view their social networks as providing them an accommodative climate espouse more life satisfaction than those who experience nonaccommodative climates. Hence, a police officer who expends time in a traffic stop apparently listening to a violator's account of his or her actions and takes his or her perspective into account, interestingly, can lead to this motorist viewing all police officers more favorably. All this suggests that being seen to underaccommodate another—for example, by staunchly maintaining and expressing one's religious ideology or blithely using English in a foreign non-Anglophone land—can be attributed negatively as self-centered, insensitive, noncaring, disrespectful, and so on. Crucially, however, CAT contends that people accommodate not necessarily where others' communication patterns actually are but where they believe them to be; stereotypes often dictate how others sound to us.

Although manifold rewards follow from carefully accommodating others, this can sometimes invoke social costs and hence, the accommodative process (as may be surmised from above) can be a quite complex one. Clearly obvious, faulty, or stereotypic mimicry can easily boomerang in terms of recipients attributing these actions to being chameleon-like or

ingratiating, or even as insincere and disingenuous, or worse as Machiavellian. In such instances, optimal levels of accommodation may be warranted so that one does not converge too much too soon, nor too quickly with an unfamiliar other, and especially toward another where unwanted romantic, or even sexual, intentions could be evident.

Miscarried convergent acts can also be transformed into signs of overaccommodation where one is seen (despite the sometimes nurturing intent) to have socially mistargeted the other. An example would be slowing down, becoming grammatically very simple, and enunciating more precisely for an elder or physically challenged person who is actually very cognitively astute; attributions of this being patronizing talk would naturally ensue. On occasion, convergence can also detract, uncomfortably, from an accommodator's feeling of a loss of their own integrity. Indeed, the need to symbolize or accentuate one's positive sense of, say, regional, national, ethnic, gender, or academic identities can be one of the principle motives for diverging from another in terms of jargon, accent, slang, physical proximity, and so forth. Obviously, diverging from a nonaccommodating or personally disdained or irritating other can also be ample reactive grounds for dissociating communicatively from them. Although diverging from others has benefits for instilling a sense of ingroup pride in the nonaccommodator (e.g., gay or adolescent), it is often (and mistakenly) construed more as a personal insult than a statement about relative intergroup inclinations and identities. In this regard, when certain American immigrants become of an age that they feel proud of their cultural heritages, they may, seemingly all-of-a-sudden, emphasize their ethnic dialects in the classroom—and in ways that White teachers could misinterpret as insolent statements about them personally.

CAT has been constituted (and been continually revised) in formal propositional terms for empirical testing, and for the most part, its elements have received support across many different languages, cultures, and social contexts. In addition, it has been invoked across various disciplines and has led to its own satellite theories in domains such as second language acquisition and intergenerational communication. The theory has been found useful in analyzing human relationships not only in face-to-face encounters but also with respect to new

media (e.g., voice-mail and e-mail). As people encounter ever-increasingly different technological means of relating to each other, CAT should, nonetheless, still have considerable explanatory power.

COMMUNICATION PROCESSES, VERBAL

Communication is integral to human relationships. Researchers who study verbal communication processes often view them as patterns of interconnections or as relational states, whether they occur between two people or between an individual and a larger audience. Similarly, scholars who study personal relationships describe verbal communication as the means by which people construct and maintain relationships. Relationships are involved in all acts of communication, and communication is the central process that gives shape to relationships.

This entry describes five basic properties of communication: *interdependence*, *reflexivity*, *complexity*, *ambiguity*, and *indeterminacy*. Of course, there are specific debates related to each of these properties, but there is wide agreement among scholars about the properties themselves and their

centrality to communication. The descriptions of each of these five properties demonstrate how the study of verbal communication and the study of human relationships intersect.

Interdependence

Interdependence refers to the idea, advocated by systems theorists, that messages simultaneously influence, and are influenced by, the messages that precede and follow them. This mutual influence creates coherence between messages and across interactions. Although similar to the view of interdependence put forth by John Thibaut and Harold Kelley, this perspective is distinct in that it focuses on the mutual influence of messages rather than on the ways that individuals affect each other's outcomes during interaction.

Interdependence accounts for the central feature of living systems—*wholeness* (or *nonsummativity*). That is, the interdependent relationships between components, rather than the components themselves, account for the unique characteristics of the whole. The application of this principle to verbal communication suggests that communication systems are defined by interdependent patterns of interaction rather than characteristics of people or messages per se. Thus, patterns are of primary interest, whereas objects (singular events or individual entities) are secondary.

Interdependence in communication is most often conceptualized in terms of two opposite response tendencies—a tendency to reciprocate or match features of the other's communication versus a tendency to compensate. For example, studies of verbal and vocal behavior indicate that, under most conditions, conversational partners automatically adapt to each other to match each other's discursive style or speech rate. In other situations, individuals may compensate for increases in physical proximity by decreasing speech volume or eye gaze.

In the research literature on personal relationships, the principle of interdependence is reflected in the study of dyadic interaction patterns. The concept of an interaction pattern presumes that there is redundancy and predictability in the way communication events or behaviors are ordered. Interaction patterns reveal a few basic things about

communication in personal relationships. First, they demonstrate ways in which communication and relationships are coherent and structured. For example, people can carry on coherent conversations because they understand the rules associated with turn taking.

Second, interaction patterns reflect multiple influences on communication, both of a proximal and distal nature. Every act of communication is enacted and interpreted within a particular historical context, including the time and place, relationship history, and history of the immediate encounter. Thus, each communication behavior is grounded in the overall context as well as in the immediate actions that precede and follow it.

Third, interaction patterns can reveal forms of relating that mediate relationship quality over time. That is, the mutual responsiveness (or reactivity) of individuals during communication predicts the quality of relationships over and above what one would assume based on overall communication base rates. Indeed, much of the research on communication in marriage is concerned with identifying patterns of interaction that predict couples' satisfaction versus distress.

Reflexivity

Reflexivity refers to the notion that communication both creates social structure and is constrained by it. The principle of reflexivity suggests that human relationships are constituted through communication. In other words, people are proactive and make communicative choices, but they also react to a variety of normative social and cultural practices that constrain their subsequent interactions.

Few researchers dispute the idea that relationships are socially constructed through communication; however, some lines of research focus on this theme more than do others. Some of the lines of research that emphasize reflexivity include the investigation of everyday discourse, relationship narratives or accounts, and relationship cultures.

Everyday Discourse

Steve Duck has made a strong argument for the symbolic force of everyday, routine conversations

in creating and sustaining relationships. Duck argues that talk, by its very occurrence, projects an image of relationships as real and enduring and thus, promotes their continuance. He also notes that talk serves as a marker of relationships. Duck says that once people agree that they are in a particular type of relationship and come to talk about it as such, their discourse changes in a number of ways. So, for example, they talk about different topics and understand those topics in different ways than they would otherwise.

Studies that explore the qualities of routine, everyday discourse often have used diary methods to examine what people talk about, when they talk, with whom they talk, and how they evaluate different forms of talk. The findings of these investigations lend support to the idea that indeed routine interactions serve as the foundation for relationships over more obviously strategic forms of communication, at least when viewed in terms of how frequently they occur.

Relationship Narratives or Accounts

The stories people tell about their associations with each other shape their relationships by delineating and reinforcing the rules and roles that define interactions. When people offer relational narratives or accounts to others, they position themselves and their partners with regard to each other and to a larger social world. They provide a portrayal of their relationship and in doing so often show how, when, and why partners behave the way they do.

Studies further suggest that the portrayals put forth in narratives are linked to relational quality—that, for example, married couples who describe themselves as having overcome obstacles together have more stable, satisfying relationships than those who do not. In fact, researchers and theorists who study narratives in close relationships argue that people often behave in ways that confirm the perceptions they hold about their associations with others. These scholars suggest that the stories individuals tell about their relationships affect the way they view their interpersonal associations and as a consequence, shape the way they perceive and respond to their partner's behavior.

Narratives also shape people's behavior when they are used to illustrate the rules and roles

associated with relationships. For instance, families who consistently tell stories about a member being sarcastic, quick-witted, and humorous may create an environment where it is difficult for that person to engage in serious conversations about emotionally charged issues. When narrators praise particular behaviors, note the usefulness of certain personality traits, or point out cases where rules or roles are violated, they create and sustain prescriptions for enacting close relationships.

Relationship Cultures

Researchers who study relationships as cultures describe relationships in terms of their ability to establish their own moral and social order, including private codes and unique interaction rules. Relationship cultures draw from conventions in the broader language community but are distinct because of jointly constructed variations in routine and common conversational practices.

There are quite a number of ways that relationship cultures manifest distinctive communicative practices. For example, over time, relational partners develop private idioms and other special vocabulary, symbols of relationship identity, routines and rituals, insider meanings, secrets, and unique rules for interaction.

Complexity

A basic notion underlying much of the literature on verbal communication is that communication conveys multiple messages simultaneously. This idea has its roots in pragmatics and Interactional Systems Theory, but it also is foundational to research on communication. For example, a number of scholars distinguish between the literal content of a message and a second, pragmatic level of meaning. The second level of meaning often is referred to as *relational communication* because it invokes a particular type of relationship. Whereas the first level of meaning tends to be explicit, the second level of meaning is relatively implicit. As such, the negotiation of relationships is an implicit subtext to all communication.

Researchers who have focused their attention on the relational aspects of communication have considered how the concepts of relationship

symmetry and *complementarity* (i.e., relative dominance) are evidenced in terms of individual utterances and recurring message sequences. Although less obvious, a similar focus on relationship negotiation is apparent in much of the research on interpersonal communication. For example, studies on communication during family conflicts are almost exclusively concerned with how families communicate about conflict and what this communication suggests about their relationships. Researchers rarely consider what families disagree about. Similarly, the research on narratives in personal relationship tends not to be concerned with the content of stories but instead focuses on how implicit features of stories and the process of storytelling are associated with relationship roles and identities.

In addition to the multiple levels of meaning that are linked to messages, several other features of interaction contribute to the complexity of verbal communication. For instance, messages are interpreted in terms of the messages that precede and follow them, including extralinguistic and contextual cues that modify meaning. Further, these various signals serve multiple functions simultaneously and may be governed by more than one set of rules. When people interact, they must integrate these multiple signals and then adapt and implement subsequent communication instantaneously in order to keep up with the normal pace of face-to-face interaction.

An issue that is frequently raised concerning the complexity of face-to-face interaction is how people are able to process rapidly changing stimuli, interpret those stimuli according to their multiple meanings and functions in the context of a matrix of other meanings, integrate all this information with multiple and sometimes conflicting goals, and then reply appropriately, without disrupting the flow of natural conversation. One explanation is that participants in communication are extremely selective about what signals they pay attention to. This perspective suggests that individuals rely on conversational devices and interpretive principles to direct their attention to the core features of messages. Another explanation is that people employ mental shortcuts both when interpreting messages and when implementing or adapting communication strategies. Consistent with the “cognitive miser” metaphor used by social psychologists, this view

suggests that cognitive processing of communication is done in such a way so as to achieve the greatest possible effect with the smallest possible effort. Yet another explanation is that communicative functions may be served by behaviors that are outside awareness. This perspective suggests that higher-order knowledge structures (i.e., broad goals) exert control over the relatively specific procedural operations that are involved in communication without requiring direct attention to those operations, except when they become problematic.

Ambiguity

A nearly universal assumption in the study of communication is that meanings are a product of negotiation. Because the coding rules associated with language and other symbolic systems are incomplete, communication is ambiguous. At the most basic level of analysis, ambiguity is reflected in linguistic *underdeterminacy*—the idea that no utterance fully encodes the thought or feeling it is used to express. Even the most explicit aspects of communication (i.e., literal meaning) rely on shared principles of inference that go beyond a surface reading of messages. Greater ambiguity is associated with the sorts of meanings that are often of interest in the study of personal relationships, such as the speech acts occurring during marital and family conflict (e.g., what counts as criticism or as validation). The meaning of a given speech act is ambiguous because the same message can perform different actions and can serve multiple functions simultaneously.

Along with the ambiguity that is inherent in language and other symbolic systems, there is also strategic ambiguity in communication. That is, speakers sometimes respond to the immediate pressure to say something coherent and appropriate with indirectness or obfuscation; they provide a response but at the same time, try to avoid saying anything too directly in an effort to preserve good relations, show politeness, maintain personal boundaries, or avoid being pinned down.

The ambiguity of communication also is illustrated by research findings that demonstrate that pragmatic and relational meanings often are seen differently by relational partners than by outside observers and that individuals who are involved in

a relationship with each other frequently perceive meanings differently as well. For instance, studies show that there is generally low-to-moderate correspondence between parent and adolescent reports of family interaction. Further, in dissatisfying relationships, spouses tend to code one another's communication in different ways, for example, by attributing negative intent to messages where none was reported by the sender or by making self-serving attributions about who is disclosing, being attentive, and collaborating versus criticizing, distorting, and changing the topic.

Another demonstration of the ambiguity of communication in personal relationships is the relatively weak empirical connection between how directly people talk about their thoughts and feelings and the extent to which others show that they understand those thoughts and feelings. Several studies of marital and dating partners have found weak or null associations between the amount of information directly disclosed during communication and mutual understanding. William Ickes explains this phenomenon partly in terms of *motivated misunderstanding*, the idea that people are sometimes motivated by desires and insecurities to maintain inaccurate conceptions about others, even in the face of explicit information that contradicts these conceptions.

Indeterminacy

Communication is indeterminate in that there are few, if any, fixed effects of messages on people or relationships. Rather, the outcomes of messages are contextual, historical, personal, and cultural. One of the main goals of communication theory and research is to articulate the critical features of contextual, historical, personal, or cultural backgrounds associated with social interaction. However, in many cases, this articulation is a difficult task because of the diverse and contradictory ways in which communication can operate.

Both General Systems Theory and Dialectical Theory support the notion that communication behaviors are associated with a number of different outcomes. General Systems Theory suggests that any final state or final condition can be achieved through different means and from different starting points. This concept, labeled *equifinality*, defies

the notion that, for example, communication goals only can be achieved using certain strategies; instead, multiple strategies may be employed to reach the same goal. Research supporting this position has demonstrated that relational partners may use different techniques to persuade each other, express opposition, and provide each other with support.

Although equifinality complicates the means by which relational partners attain particular outcomes, *multifinality*, a related component of General Systems Theory, suggests that the same starting point may result in different outcomes. A communication strategy employed in one relationship may encourage satisfaction, while in another relationship the same strategy may create distress. For instance, researchers have found that in some cases the expression of negative affect is harmful to relationships, whereas in others, it is positively associated with or unrelated to satisfaction. Studies show that negative behavior is inversely associated with relational satisfaction overall, but it would be short-sighted to conclude that negative behavior is always harmful to relationships.

Dialectical Theory takes another approach to examining the indeterminacy of communication. Rather than emphasize the various paths between starting points and outcomes, this theory suggests that the process of relating can be viewed as a dialogue about opposing or contradictory forces. Scholars who employ Dialectical Theory suggest, for example, that people desire both autonomy and connection in their personal relationships. The way partners negotiate these two opposing forces is part of what defines their relationship.

Although most communication researchers accept the basic arguments concerning dialectical contradictions and equifinality-multifinality, they may be less clear about how to integrate these arguments into their empirical work. For example, the most pervasive research strategy for assessing the impacts of communication on relationships is to evaluate the effects of communication based on their observed association with relational satisfaction or distress. This strategy often carries the implication that the interaction characteristics discriminating these groups can be categorized as good or bad communication. However, studies suggest that good, sophisticated, or skillful communication does not necessarily distinguish satisfied

from dissatisfied couples. In fact, there is evidence that some couples who are unhappy employ very skillful, effective strategies to hurt each other and that seemingly positive behaviors can result in unnecessary and damaging patterns of accommodation.

Conclusion

Although the properties discussed in this entry—interdependence, reflexivity, complexity, ambiguity, and indeterminacy—are basic qualities of communication, they pose challenges to researchers and theorists that are notably complex. Perhaps the most obvious of these challenges is for researchers to devise ways to study the multiple meanings, functions, and outcomes associated with communication behaviors. Another is for scholars to study and analyze interactions and sequences of interactions, as opposed to individual strategies, turns, or utterances. Researchers also need to attend to the contextual nature of communication so that they can begin to understand the nuanced influences of historical, relational, and cultural contexts on social interaction.

COMMUNICATION SKILLS

Communication, like any other activity, can be done well or poorly. Just as people may have abilities that make them good surgeons, musicians, or athletes, individuals may possess skills that allow them to function well in interactions with others. Scholars have grappled with the problem of trying to define exactly what the term *communication skill* means, and numerous conceptions have been proposed (and various related terms such as *social skills* and *communication competence* have been introduced), but a great number of these conceptions center around the idea that communication skills involve effective and appropriate communication behaviors. That is, communication skills involve the ability to be effective in the sense that a person can accomplish his or her goals while also behaving in ways that are socially acceptable or desirable.

The study of communication skills has a very long history and is also extremely broad. It is at the center of the field of communication (where virtually every branch of the discipline is concerned in some way with communicating more effectively and appropriately), but it is also an important topic for scholars in psychology, philosophy, business management and human resources, family studies, and education. Communication skills (or lack thereof) are manifested at every turn in human endeavors: dating and marriage, parent–child interactions, friendship,

job interviews, business presentations, group meetings, bargaining and negotiation, teaching and learning, physician–patient interactions, and on and on. And what is especially noteworthy about communication skills in all of these contexts is that research shows that they play a key role in the participants' success and satisfaction, both with respect to the immediate interaction and with their long-term relationship.

The Importance of Communication Skills

A great deal of research has focused on the relationship between communication skills and various aspects of a person's occupational, relational, psychological, and physiological life. This research operationalizes communication skill in various ways and does not always produce uniform results, but on balance, there is strong evidence that communication skills are related to many sorts of positive outcomes. For example, one might expect that people with good communication skills would experience greater academic success, and there are studies that confirm this relationship. Similarly, skilled communicators are likely to do better in job interviews, and once hired, those with greater communication skills tend to perform better in their jobs and even to make more money than their less skilled counterparts. It is not by coincidence that recruiters consistently rank communication skills as one of the most important qualities they look for in a prospective job candidate.

But the importance of communication skills is not limited to the classroom, office, shop, and sales floor. Good communication skills are also related to the quality of one's interpersonal relationships. Skilled communicators tend to have more positive experiences in dating and romantic relationships. Those who are married tend to be happier in their marriages—so much so that certain communication skills are strong predictors of the likelihood of divorce. It is not surprising, then, that people with good communication skills are less likely to experience feelings of loneliness.

And the psychological factors associated with communication skills extend far beyond feelings of loneliness. For example, those with low skills are also more likely to experience anxiety and depression. It is important to note, though, that in many

of these studies the direction of causality is not clear (i.e., do low skills lead to the psychological condition, or does the psychological condition lead to low skills?). Finally, just as communication skills are related to people's mental well-being, they are also related to individuals' physical health. For example, people with low skills are also more likely to suffer from cardiovascular disease and other physiological problems. It is noteworthy, too, that people who are interpersonally isolated (something less likely to happen for skilled communicators) experience higher mortality rates.

Mapping the Domain: Types of Communication Skills

The previous section notwithstanding, it is somewhat misleading to think of a person as being skilled or unskilled because there are actually many distinct abilities that contribute to making a person a more effective and appropriate communicator. Just as a baseball pitcher might possess certain abilities (e.g., a good fastball) and not others (e.g., good control), a person might possess some communication skills but not others. Many different approaches for classifying the various types of communication skills have been developed, and no single one has come into widespread use, but it is possible, at least, to specify some of the key skills that tend to be identified by numerous authors. Furthermore, as a way of organizing these skills, it is useful to think in terms of a general hierarchy of functions that they serve.

Fundamental Functions: Encoding and Decoding Processes

At the most fundamental level of the function-based skills hierarchy are those skills involved in producing effective and appropriate verbal and nonverbal messages and in attending and interpreting the messages of others. Encoding skills, then, include such things as command of requisite vocabulary, grammar, and pronunciation; the ability to produce effective nonverbal behaviors such as facial expressions and vocalic cues; and because message planning has been shown to be an important component of skillful interaction, encoding skills also include such things as the ability to

anticipate how others are likely to respond and to choose among behavioral alternatives.

Fundamental decoding skills are those involved in processing stimulus inputs. Like encoding skills, they include a wide variety of activities, including allocating attention to the most important or relevant aspects of the environment, listening, organizing and classifying inputs in appropriate ways, correctly interpreting the verbal and nonverbal behavior of others, and sizing up people and situations.

Interaction Functions: Self-Presentation, Relationship Negotiation, and Interaction Management Processes

At the mid-level of the function hierarchy are skills related to basic needs and demands that arise when people interact with others and that, as a result, characterize most, if not all, of those interactions. Among these is a concern with self-presentation. Following from the work of Erving Goffman and others, scholars have come to recognize that one of people's overarching social concerns is with the kind of impression they create in the minds of others. People want, for example, to be seen as intelligent, honest, friendly, and so on. And yet, there is skill involved in self-presentation, and people often come across in ways very different from what they intended.

A second social function manifested in virtually every human interaction is the presentation and negotiation of the relationship between the interactants. Whenever people communicate—whether with a stranger, customer, coworker, close friend, or lover—they present their view of their relationship with the other (and the other person, simultaneously, does the same). The presentation and negotiation of relationships is typically subtle, but at times it can be complex and difficult: Two people's definition of their relationship may not coincide (e.g., peer vs. subordinate), or one or both of them may be seeking to change the nature of their relationship (e.g., from friend to romantic partner). Whatever the circumstances, there are skills involved in navigating the waters of relational communication in ways that are satisfying for both parties.

A third example of a mid-level function in the hierarchy involves interaction management skills. By their very nature, conversations involve a complex interweaving of the interlocutors' behavior.

Before an interaction ever begins, there are issues of whether or how to initiate interaction. During interactions, people must engage in the exchange of speaking turns; they deal with interruptions and talk overs; they must respond to the conversational contributions of their partners; they decide whether to extend or change the topic. As an interaction comes to a close, there are skills involved in understanding and signaling that fact. Interaction management skills, then, are involved in people's ability to coordinate their behavior with that of others: Greetings, conversations, and leave-taking can proceed smoothly, with each person seemingly in sync with the other, or they can be awkward and difficult.

Social Task Functions: Context Specific Processes

At the upper level of the skills hierarchy is a whole host of skills related to specific social contexts and goals. Unlike the first two levels, which apply to virtually all interactions, these skills are related to functions and objectives that arise in particular settings. The list of skills at this level, then, is extensive indeed. For example, it includes skills related to informing and explaining, persuasion and social influence, providing support and encouragement, giving advice and counsel, managing conflict, negotiation, interviewing, group discussion and decision making, and public speaking.

General Features of Skillful Communication

The specific behaviors that constitute skilled communication will, quite naturally, vary from situation to situation (e.g., the verbal and nonverbal behaviors that are likely to be appropriate at a party are less likely to be so at a funeral). Nevertheless, it is possible to identify from the relevant research certain general features that tend to characterize behaviors that are perceived as more effective and appropriate. Among these general principles are the following five, plus two additional overarching principles:

1. Behavior tends to be perceived more positively when it reflects another orientation. People who are able to convey attentiveness, interest, and responsiveness to their interlocutors are likely to be viewed as more socially skilled than those who seem bored, disinterested, or self-absorbed.

2. Behavior tends to be perceived more positively when it reflects a higher level of energy. People who are enthusiastic, expressive, and energetic are more likely to be viewed as socially skilled than their counterparts who seem lethargic and slow.
3. Behavior tends to be perceived more positively when it is rewarding. People who, for example, convey respect for their conversational partners, or who praise and compliment others, tend to be perceived as more socially skilled than those who are sarcastic, cynical, and punishing.
4. Behavior tends to be perceived more positively when it reflects an appropriate understanding of the nature of the relationship between the interactants. Interpersonal relationships differ along a number of dimensions, and people whose behavior suggests an accurate conception of their relationship with another along these various dimensions tend to come across as being more skilled. For example, relationships differ in the level of intimacy or closeness between those involved, and people may behave in ways that seem too chummy (or too distant). Similarly, there is a power dimension to relationships, and those who seem too bossy (or too submissive) may be perceived as less appropriate and effective.
5. Behaviors that reflect a lack of composure or decorum tend to be perceived in negative ways. Many examples are possible here, but they include such things as losing one's temper and similar instances of a lack of emotional control, as well as behaviors such as nail biting and other actions related to personal hygiene.

Beyond these five general principles, then, there are two additional ones that trump the others in the sense that they suggest qualifications and conditions on the first five:

1. Behavior tends to be perceived more positively at moderate levels. Virtually any behavior is less effective and appropriate when there is either too little or too much of it. Whether it be eye contact, smiling, speech rate, self-disclosure, or whatever—anything can be overdone. And applied to the five general principles listed above, although it is true that more energetic and animated people may be perceived more positively, it is possible to be too energetic; rewarding people may come across as more socially skilled, but the principle has its limits.

2. Behavior tends to be perceived more positively when it is adapted to one's interlocutor, the relationship, and situation. The importance of this principle is to suggest that none of the previous principles will apply in every social interaction. There will always be exceptions to any set of guidelines for what constitutes effective and appropriate behavior.

Skill Acquisition and Skill Training

People are not born with skills (although people may be born with predispositions and characteristics that facilitate skill acquisition); instead, skills are acquired over time. And in the case of complex skills, the process of skill acquisition tends to be rather gradual. In fact, research on skill acquisition in a number of domains has led researchers to posit the 10-year rule: Achieving truly expert performance requires approximately 10 years of focused practice. If one charts the course of performance improvement (y axis) over time (x axis), the graph for almost any skill will be a decelerating (power) curve. In the early stages of practice, performance tends to improve a great deal, but the pace of performance improvement tends to slow, and after several years of practice, it approaches an asymptote.

There are a number of behavioral and cognitive changes that mark the course of skill acquisition, including (a) speed—experts are faster than novices; (b) accuracy—as skill improves, people make fewer mistakes or errors; (c) flexibility—more experienced individuals are better able to adapt to new and changing circumstances; (d) cognitive effort—in the early stages of skill acquisition, people have to concentrate on what they are doing, but over time, the mental work involved in carrying out the skill diminishes; (e) multiple-task performance—one of the implications of reduction in cognitive workload is that experts find it easier to do more than one thing at a time; and (f) a more abstract and sophisticated conception of behavior—rather than thinking about and monitoring the low-level, concrete details of their actions, experts tend to see what they are doing in a more abstract, big-picture way.

Numerous training programs for improving communication skills have been developed, and although they differ in their details, they do tend to reflect certain common elements:

Instruction. Skill acquisition is facilitated when people have a clear understanding of what they need to do. It is important, then, to provide explicit guidelines about what skilled behavior in a particular domain entails. Instruction may also include the presentation of models of skilled performance that reflect the desired attributes, as well as models of what not to do.

Practice. It is generally accepted that practice is essential for skill acquisition. Most typically, practice involves efforts to actually implement desired behaviors in real or simulated social contexts, but practice can take other forms, including mental rehearsal, workbook assignments, and so on. Practice tends to be most effective when people concentrate in a focused way on the details of their behavior in an effort to meet the guidelines they are trying to master.

Feedback. To more closely match behavioral ideals, people need feedback about their performances. Without such information, it may be difficult to know what sort of changes need to be made. Feedback is more effective when it is adapted to learners' own understanding of what they should be doing. So, for example, in the early stages of skill acquisition, when people tend to operate with relatively low-level, concrete conceptions of the activity, feedback ought to be couched in similar terms. As individuals acquire increasingly more abstract understandings of the activity, the most effective feedback will correspond to their construals of what they are doing.

In discussing skill-training programs, it is important to note that skill acquisition does not insure skill retention and transfer (see the discussion of skill failures below). It is typically possible to bring about improvements in various measures of skill acquisition, but this does not guarantee that people will retain that knowledge or ability over some span of time. And perhaps even more significantly, skills acquired in training and classroom settings very often fail to transfer to the real-world contexts where they are relevant.

Skill Assessment

There are a great many alternative approaches to performance assessment, and they resist easy classification, but one rudimentary scheme for organizing

assessment procedures is to classify them in terms of *level* and *method*. Level essentially concerns how fine-grained a skill assessment is. Assessments may, for example, involve (a) global evaluations of overall communication skill, (b) assessments of an individual's abilities with respect to various skill domains such as those described earlier, or (c) at a very molecular level, assessments of specific behavioral features such as eye contact, gestures, and so on. Although level concerns what is being assessed, method involves how those assessments are made. The possibilities, again, are numerous, but among the most common techniques are self- and observer ratings of performance quality in actual or simulated interactions, administration of established scales designed to tap perceptions of either one's own or another's skill level, assessment of accuracy or quality with respect to some objective standard (e.g., accuracy in detecting deception), and frequency counts and duration measures of behavioral cues taken to be indicative of either skilled or unskilled communication (e.g., self-adaptors).

Skill Failures

As important as communication skill is, the fact remains that people very often fail to act in socially appropriate and effective ways. Much research, then, has focused on understanding the sources of skill failure. One major tradition of thought identifies two broad classes of factors underlying skill failures: knowledge (including the ability to use that knowledge) and motivation. In simplest terms, in order to behave in a skilled manner, a person must possess requisite knowledge and ability and be motivated to actually put that knowledge and ability to work. When either factor is deficient or absent (for any of a variety of reasons), performance is likely to be less than optimal.

A second approach to understanding skill failures is prompted by the common observation that in many cases people possess necessary knowledge and motivation and yet still do not behave in a skillful way. Such phenomena suggest that skill failures may be the result of characteristics of the cognitive structures and processes that give rise to behavior. For example, cognitive theories of behavioral production typically posit that the memory structures used to produce behavior are strengthened through

use and that stronger memory structures are more accessible. From this perspective, then, a person may have information necessary for effective action stored in memory but fail to retrieve that information when it is needed.

COMMUNITY INVOLVEMENT

Community involvement encompasses the many ways individuals from the same place (e.g., from a specific town or neighborhood) or with similar interests (e.g., a professional association or individuals pursuing a given hobby) interact with one another within a common context. The interactions include, but are not limited to, volunteerism, community organizing, social action, citizenship behaviors, and neighboring. Community

involvement precipitates and reflects connections between self and others, providing opportunities for relationships to develop between individuals, between individuals and agencies or organizations, and between individuals and their communities. This entry considers dimensions of community involvement, factors believed to motivate such involvement, and consequences of involvement.

Dimensions of Community Involvement

Community involvement can take on many forms, varying across multiple dimensions; the anchors of a subset of such dimensions are described in this entry.

Involvement can be formal or informal, varying in degree of structure and commitment. As two examples from the formal end of the spectrum, an elected official holds set responsibilities within an organization for a specified period of time, and a volunteer at a nonprofit agency perhaps commits to answering a crisis hotline for 3 hours on the same night of each week. Informal involvement, on the other hand, is less structured and likely involves no explicit commitment to continue involvement. A citizen might call the authorities to report a suspicious person lurking near an elementary school; a family might regularly introduce newcomers on the block to the long-time residents.

Involvement also varies in terms of duration. It can be sustained (e.g., a long-term member of the school board), intermittent (e.g., a person who participates in neighborhood beautification projects every few years), or one-shot (e.g., a person who attends a community parade once during his or her residency).

Although community involvement is generally a social pursuit in as much as it contributes to the social fabric of broader collectives, it nevertheless varies in the extent to which the actions themselves are social. Others need not necessarily be involved in order for an action to qualify as community involvement. Examples of potentially solo actions that could nevertheless constitute community involvement include picking up a piece of litter in the park, writing a letter to the newspaper editor, maintaining a Web site for a hobbyist group, and reading a poster announcing a lost pet. If others are involved, they may be total strangers (e.g.,

marchers at a public protest), familiar others (e.g., individuals attending a Neighborhood Watch meeting or regular participants in an online community of cancer survivors), or even close friends (e.g., a small group of families who take turns preparing weekday meals for the other families).

Factors That Motivate Community Involvement

A complex constellation of factors compel individuals to become involved in their communities. These factors range from the purely situational (e.g., welcoming a stranger into one's home after a devastating natural disaster hits the community) to the purely psychological (e.g., assuaging feelings of loneliness by volunteering one's time at an agency). Factors motivating involvement fall roughly into three categories: other-focused, self-focused, and mandated.

Individuals motivated by other-focused interests generally seek to improve the lives of other people, ranging from a specific person (e.g., a child in the Big Brothers Big Sisters program) to society at large (e.g., as in the case of an environmental activist seeking to improve the world for her or his descendants). In contrast, individuals motivated by self-focused interests seek to improve or express some aspects of one's own life. A partial list of such self-focused motivations include a desire to fulfill value-based goals (e.g., religious, political, humanitarian), to fulfill a need to belong to a social group, to increase one's self-esteem, to promote one's own career, to gain skills or knowledge, to nurture generativity, and to expand one's social network.

As suggested by the category label, mandated involvement is required in some way. Examples of mandated involvement include service-learning (in which an educator pairs required community involvement with classroom experiences so that the two kinds of exposure to a particular topic can strengthen and broaden students' learning) and court-mandated involvement (e.g., a judge might require a drug offender to speak to junior high students about the risks of drug use).

Importantly, an individual might at once be motivated by any number of other-focused, self-focused, or mandated factors, and the relative dominance of these factors varies across individuals.

Consequences of Community Involvement

Community involvement holds meaningful consequences, both benefits and costs, for individual engagers, the recipients of some types of involvement, the agencies or organizations in which involvers participate (if applicable), the community in which the involvement occurs, and society in general.

The individual who involves herself or himself in the community stands to fulfill the social, psychological, and functional needs suggested by the motivations listed above. This encyclopedia's focus on human relationships calls for additional comment about the relational outcomes of involvement. Engaging in one's community presents an opportunity to meet and interact with other people. Importantly, in the case of communities of interests, the others with whom the engager interacts likely hold at least some similar views, interests, and attitudes; these similarities provide a medium for nurturing friendships and romantic attractions. In the case of geographic communities, the person who engages in her or his community may cross paths regularly with other engagers, thus increasing the opportunity for different engagers to become familiar with one another; like similarity, this familiarity sets the stage for potential friendships and romantic relationships.

Given that some types of involvement involve explicit support of others, involvement holds potential consequences for recipients or targets of involvement. For example, a parent who contributes time and energy to a parent-teachers association benefits the school's children, teachers, and administrators. Likewise, entire organizations benefit from the community involvement of individuals. Potential benefits include free (as in the case of volunteers) or low-cost (as in the case of many public officials) people power, an influx of creativity and knowledge, and goodwill within the broader community. In turn, the broader community and society in general benefit from the increase in social capital afforded by an involved citizenship.

Involvement also incurs costs. It takes individuals' time, attention, and perhaps even money. Recipients of well-intentioned support might actually experience the support as ill-timed, ineffective, or unwanted. Agencies and organizations

incur costs as they attempt to recruit, manage, and retain volunteers and activists.

In spite of the costs associated with community involvement, it is nevertheless generally valued. In total, community involvement reflects and contributes to psychological sense of community, which David W. McMillan and David M. Chavis describe as consisting of a shared emotional connection, an ability to affect one's civic entity or organization, an ability of the community to fill one's needs for support (often because of community members' ability to work together), a sense of membership or belongingness within a community, and a conscious identification with the community.

COMPARISON LEVELS

Comparison levels are an individual's expectations for the quality of a close relationship and the alternatives they have to that relationship. The *comparison level* (CL) is the standard that an individual uses to determine how satisfied he or she is with a specific relationship, which depends on the expected ratio of rewards-to-costs in that relationship. The *comparison level for alternatives* (CL_{alt}) is the minimal reward-to-cost ratio that an individual will accept to stay in a relationship, taking

into account the expected reward-to-cost ratio of the best available alternative. During the course of a relationship, if an individual's CL drops below his or her CL_{alt} for that relationship, then he or she will likely exit that relationship.

There are many determinants of CL and CL_{alt} including the quality of the existing relationship and the availability of alternatives to the relationship. CL and CL_{alt} also determine outcomes in a relationship including how committed an individual is to a relationship and how much he or she will sacrifice for that relationship. Comparison levels are a concept in social exchange theories of relationships, which view relationships as an economic system of rewards, costs, and investments. This entry reviews the determinants of comparison levels and how they affect an individual's likelihood of continuing the relationship.

CL and Relationship Satisfaction

Every relationship has rewards and costs. Rewards can be things like financial security, a supportive partner, and connections to a larger social network. Costs include time sacrificed from other interests, relationship conflict, and the partner's annoying habits. Everyone has certain expectations about what he or she deserves in his or her relationship, which determines his or her CL. These expectations are based on an individual's experience with previous relationships (parents, friends, romantic partners) and observations of other relationships. If the actual ratio of rewards-to-costs is higher than what he or she expects, then the individual will be satisfied with his or her relationship. If this ratio is lower than what he or she expects, then the individual will be dissatisfied with the relationship. Perceptions of rewards and costs can change over time. In successful relationships, people believe that their rewards grow more rapidly than the costs, making the relationships more satisfying and less likely to end.

Investments in a Relationship

Across time there are certain investments in relationships, such as financial and emotional resources, that would be sacrificed if the relationship ended. This sacrifice increases the cost

of ending the relationship and lowers the CL_{alt} . For example, couples spend more time together, combine their finances, and integrate their social networks. It is much easier to leave a dating relationship where both partners live apart than a marriage where the partners have purchased a house together. Therefore, when there are few investments that are easily forfeited, individuals are more likely to end their relationship. In contrast, a relationship with many investments increases the cost of ending that relationship.

Attractive Alternatives

Individuals always have alternatives to the relationship. They can start another similar type of relationship by finding a new romantic partner, they could become single, or they could start a different type of relationship, such as leaving a parent's home to marry. The quality of an individual's alternatives to the relationship (CL_{alt}) is based on the potential rewards and costs of the alternative. A new romantic partner may be better looking or nicer and being single may leave more time for personal pursuits, thereby raising the CL_{alt} . At the same time, individuals will lose all of the investments they have made in their current relationships and acquire the costs of the alternative. A new relationship will take time and effort, and being single may be lonely, thereby lowering the CL_{alt} . When the alternatives to a relationship are of high quality, the CL_{alt} will grow. At that point, the individual is more likely to leave his or her existing relationship.

The Relationship Between CL and CL_{alt}

In general, as a relationship becomes more satisfying (the ratio of rewards-to-costs is higher than the CL), individuals will raise their standards for alternatives to the relationships (lowering the CL_{alt}) making it less likely for people to leave the relationship. People who are highly committed to their relationship, relative to those who are less committed, pay less attention to attractive alternatives and often derogate attractive alternatives by seeing them as less attractive. Moreover, individuals who are feeling love for their romantic partners

are better able to push thoughts of attractive alternatives out of their minds.

But even committed relationships can be endangered by attractive alternatives. Even when individuals are in committed relationships, they will often pay attention to highly attractive alternatives. When individuals are in an environment with many attractive alternatives, the environment can change how these people perceive their own relationship. If people perceive their environments to be filled with attractive alternative partners (raising the CL_{alt}), they become less committed to their current relationship. Thus, across time, an individual's CL and CL_{alt} can change as the rewards and costs of the relationship change, the amount of investment in the relationship increases, and the quality and number of alternatives in the environment changes. Because these aspects of a relationship change, individuals' commitment to their relationships will vary across time.

COMPASSIONATE LOVE

Compassionate love is centered on the good of the other. The expressions *compassionate love* and the closely related *altruistic love* are used in recent research to identify a self-giving, caring love that values the other highly and has the intention of giving full life to the other, promoting flourishing. At the core of the construct are motivation, discernment, and a freely chosen decision to give. The *why* of the action, the reason for the behavior, the motivation behind the action—all are important to categorizing attitudes and actions as compassionately loving in nature. Compassionate love can be expressed in the context of other kinds of love such as romantic love and familial affection and in the context of altruistic actions but reaches beyond them. Compassionate love is not always in response to the suffering of another; it also includes attitudes and actions designed to encourage the flourishing and growth of another at a cost to self. This kind of love is a central feature in many religious traditions but is not necessarily tied to any particular religion.

Certain qualities are central to compassionate love: (a) choosing freely to give of self for the benefit of the other; (b) some degree of cognitive understanding of the situation of the other and of oneself; (c) valuing the other at a fundamental level; (d) openness and receptivity, leaving space for receptivity to the divine if relevant; and (e) response of the heart, the integrative core of one's being. Some affective quality is usually part of this kind of attitude or action, and moral decision making has been seen in empirical studies to involve affective as well as cognitive areas of the brain and body. This entry builds on this definition of compassionate love and articulates a model that is useful in fleshing out the construct, interpreting research in the area, and creating applications of research.

Operational Model

Lynn Underwood developed a model that has been useful in developing research in this area and in applying that research to practical situations. The starting point of the model, the substrate of compassionate love, consists of individual variations in

personality, biology, and developmental patterns nested within and shaped by cultural, historical, family, and social environments. Although none of these factors necessarily determine whether a person will be compassionately loving, they can increase or decrease the possibility of such behavior. Individuals, with their different initial conditions, or substrate, encounter specific situations and relationships. They engage with motivation and discernment and then make choices resulting in action or expression of attitude. There is also a feedback loop. Actions feed back on the individual, affecting the development of the person over time. The outcomes of actions and the effect of being loving itself can both exert feedback on the development of the person. Some examples follow that indicate the kinds of research that are emerging in this area and that help to flesh out this basic model.

Elaboration of the Model With Research Findings and Possibilities

Substrate

Relevant factors that affect one's capacity to express compassionate love include such things as how well one was loved as a child, one's religious and cultural environment, and one's inherited disposition. For example, it has been shown that empathic concern, but not perspective-taking empathy, may be inherited to some extent and that extraverts may find it easier to reach out to a stranger than introverts. Empathy can also be taught in a parental or social context. Physical factors are also part of the substrate. The old or disabled are less able to offer physical assistance to a person in need, even if the desire exists. Although none of these factors necessarily determine whether a person will be compassionately loving, they increase or decrease the probability of such behavior and the form it can take. These substrate factors, which can change over time, can be thought of as limitations of freedom, as they may constrain the capacity to love, but these substrate factors can also boost the capacity to express love.

Specific Situations and Relationships

The expression of compassionate love can also be affected by the specific situation and the relationship

to the person being loved. It is easier to love ingroup members than outgroup members. Most people have a distinct sense of the stranger that affects how they relate to people. The particular physical expressions of compassionate love as expressed in marriage differ from its expression in interactions with strangers. One illustration of how specific situations and relationships can affect compassionate love comes from brain-imaging studies of mothers viewing photographs of babies. There is a very different physiological response in the area of the brain correlated with positive mood when mothers view photographs of their own babies when compared to photographs of other babies. Economic structures can also affect when and how compassionate love is expressed. In the health care systems of the United States and many other countries, a fee for service or fee for time arrangement can result in actions by health care providers primarily motivated by duty, obligation, and profit. However, even in such a system, there is flexibility that provides opportunity to go the extra mile for the patient or to engage in compassionate caring for the sick person.

Motivation

Motivation and discernment are an integral part of the moment of choice and are crucial to the definition of compassionate or altruistic love. Motives are always mixed, and self-centered motives can dominate other-centered motives. Motivation is the driving force for other-centered actions and attitudes. People overcome inertia or self-centered tendencies through strength of motive. Compassionate love springs from valuing in the other person highly at a fundamental level and a desire to see the person flourish—that is, the driving force of the action or words. This competes within the person with egocentric desires for comfort and success. The kinds of motives that can get in the way of compassionate love include the need for reciprocal love and affection, the need to be accepted by others or by God, the need to belong, the feeling of guilt and/or fear, the seeing of the other as an extension or reflection of the self, the feeling of pleasure in looking well in the eyes of others, the control of the other through their indebtedness, the desire to exercise power over others, the desire to reinforce positive image of self and feelings of superiority, and/or the desire to

avoid confrontation. These kinds of internal struggles were articulated in interviews during the development of Underwood's Daily Spiritual Experience scale which included self-report items relevant to compassionate love such as "I feel a selfless caring for others" scored on a Likert scale (many times a day to never or almost never). In interviews of inner-city women, for example, this report did not correspond with self-abnegation but with attitudes that centered on the good of the other at substantive cost to oneself. Those reporting this could describe the force of this inner attitude and its weight in decisions to act or speak out. It can show itself in actions such as helping take care of the aging parent of someone else in the community or as offering a kind supportive word when exhausted at the end of a long day of work. (A more dramatic example of compassionate love would be those who rescued others in the Holocaust at substantial risk to their own well-being.) In the 2005 General Social Survey, 11.5 percent of the population reported having an experience of selfless caring for others many times a day or every day, 43.7 percent most days or some days, and 14 percent never or almost never.

The primary way to understand motive is through self-report. However, people often do not understand their own motives and also like to portray them as more positive than they are. Therefore, other techniques are needed to uncover motives. For example, experimental social psychology has techniques that attempt to isolate altruistic motives. Other innovative techniques, such as those used by behavioral economists, rely on game theory to identify controlled situations in which motive can be elucidated. Neural imaging can also compare areas of the brain that have increased blood flow during various self-reports and correlate them with responses when confronted with scenarios that elicit other-centered attitudes. Further understanding of the motives relevant to compassionate love can be facilitated by using subjects who are particularly aware of the myriad of motives involved in actions. People can be trained to reflect on motivation and to become more self-aware. An example of this was found in a set of interviews of Christian monks. These men value compassionate love highly in their living situation and are trained to reflect and recognize motives such as self-aggrandizement and other self-centered motives, as they are

encouraged to continually work toward actions centered on the good of the other. These actions can be seen in simple situations such as allowing another person to step in front of oneself in line at meals or graciously encouraging a more qualified man to be assigned to a position that one had desired for oneself. Studies of particular groups who value compassionate love and strive to incorporate it into their lives at cost to self can also give greater insight into how these motives operate.

Discernment

Discernment is also important and closely linked with motivation. Discernment involves weighing situations, both explicitly and intuitively. Compassionate love fully expressed is not just good intentions but is applying the discipline of discernment as well as one can to decide what is really good for the other in order to implement it. This discernment involves balancing competing factors. One must assert appropriate self-interests while caring for others. People continually balance short-term versus long-term considerations. The needs of others who are close and cared for must be balanced with those of strangers or more distant others. People must balance giving and receiving. Rather than taking the moral high ground and always being on the giving side, in some circumstances the compassionately loving thing is to allow the other person to give. This takes place in the l'Arche communities where those with mental handicaps are seen as people with gifts to give others in the communities, not just passive recipients of care. And finally, justice and fairness must be balanced with mercy. One may judge that it is ultimately the most loving to establish a more just society that promotes more caring behavior overall, even when it requires less than compassionate behavior toward an individual. One may even do this at cost to oneself. These choices are not easy.

Compassionate love also leaves an opening for the divine, God, or the transcendent as an effect on the substrate and as an influence on motivation and choice. For example, for some people, divine love is perceived to affect them either directly or through other people, and they find that this enables them to be loving when they are otherwise inclined. For many who believe in the existence of the transcendent, compassionate love

exists in a religious or spiritual context of love, grace, or gratitude.

Behavioral Outcomes

Actions and attitudes may be outcomes of compassionate love, but observed altruistic behaviors such as organ donation, volunteering, and supporting others in a social context can be the result of either self-centered (e.g., to be seen as a virtuous person) or other-centered motives. Behavioral outcomes are only one part of the assessment of compassionate love and are never definitive. In this model, motivation and discernment centered on the good of the other leads to loving action when the inhibiting effects of the substrate (physical, emotional, social environmental, cultural), relationship, or situation do not excessively interfere.

Conclusion

Experiencing love from another that is based on valuing a person fundamentally rather than valuing a person's functional performance or utility is one of the things that makes life worth living. When people express love with motives that seem centered on the good of the other, with cost to self, it can have a powerful impact. It is only by combining outcomes and assessing substrates, motivation, and discernment that the presence of compassionate love can be assessed. Further exploration into the causes and impediments to this behavior has potential to create a better living environment and improve social conditions.

COMPATIBILITY

According to standard dictionary definitions, *compatibility* refers to the ability of two parties to peacefully coexist, whereas *incompatibility* refers to their inability to do so. Metaphorically, this distinction can be illustrated by the difference between one set of gears that are precisely matched to each other and a second set of gears that are badly mismatched. Well-matched gears operate together in a smooth, synchronized manner; mismatched gears grind and grate against each other, producing heat, noise, mutual wear and tear, and sometimes, a complete mutual inhibition of movement.

Obviously, human relationships are far more complicated than the movements of a set of mechanical gears. However, in the human context as well, the essential distinction between a smooth coordination of respective movements (*compatibility*) versus a grating clash of respective movements (*incompatibility*) is equally valid. Given this basic distinction, the current entry reviews some important factors that directly influence compatibility in close relationships, and then concludes with a brief consideration of marital interaction and options for treating marital incompatibility.

A formal theoretical account of the difference between compatibility and incompatibility has been provided by Ellen Berscheid, who focused specifically on the intra- and interchained activities of the relationship members:

That portion of the relationship's infrastructure . . . that is especially relevant to the relationship's compatibility or incompatibility is that portion that encompasses activities that are intrachained—or, in other words, that portion that represents each

partner's organized action sequences and higher-order plans. Thus, whether—and how—the individual's sequences and plans impinge on the partner's sequences and plans (and vice versa) should determine the emotional tenor of the relationship. Where interchain connections between the partners interrupt one or both persons' intrachain activities, negative emotion should result; where interchain connections facilitate each person's performance of intrachain activities, or where there are no interchain connections to these activities, harmony should prevail. In the beginning of a relationship, both persons bring with them a lifetime of organized behavior sequences as well as current plans in progress. How these two sets of intrachain activities fit together not only helps to determine whether the relationship will be compatible or incompatible, close or distant, but also whether it shall live or die. (1985, p. 153)

Each individual has many different goals, plans, and habit patterns, and it is a constant challenge for each individual to juggle, sequence, and align them in a way that minimizes the possibility of their conflicting with each other as intrachained activities. It is an even greater challenge for two individuals—as relationship partners—to not only juggle, sequence, and align their individual goals, plans, and habit patterns but at the same time avoid disrupting each other's attempts to accomplish this task through the interchained, interconnected activities that represent all of the ways in which they are behaviorally and cognitively interdependent with each other. Because the potential for such disruption is often present and hard to avoid, the task of maintaining a compatible relationship is, at times, a difficult and complicated one.

Theory and research findings suggest that compatibility depends to a large extent on the partners' ability to understand each other and to anticipate each other's respective thoughts, feelings, goals, motives, and habitual and planned behaviors. Such understanding enables the partners to preemptively avoid disrupting each other's interchained activities (although such disruptions may, at times, be initiated intentionally—often for the purpose of avoiding an even greater anticipated disruption later on). Among the many factors that affect such understanding are the ones described below, as

identified by various contributors to William Ickes's edited book, *Compatible and Incompatible Relationships*.

Predictability

According to D. W. Rajecki, mammalian species whose members live together in groups will typically threaten, attack, and even kill unfamiliar members of their species who look and act differently. Rajecki argued that this xenophobic response is an evolved adaptation that helps to solve the problem of nonkin attempting to enter one's group and compete for the resources (e.g., food, potential mates) that are needed to ensure one's personal survival and the ability to pass on one's genes through reproduction. If his analysis is correct, humans as well as other social mammals may be biologically predisposed to have incompatible relationships with unfamiliar and dissimilar others.

Level of Cognitive and Social Development

Because parents are, in virtually every case, more cognitively and socially developed than their children, parents have a greater responsibility than their children to apply their skills in order to make the parent-child relationship a compatible one. They must be patient with the child's limitations, try to accommodate these limitations at each stage of the child's development, and encourage the child to transcend them. Parents' failures to do this can result in problems and delays in the child's development and—in extreme cases—in acts of child abuse.

Level of Behavioral and Cognitive Interdependence

According to Berscheid, a high level of behavioral interdependence is like a two-edged sword. On the one hand, it enables relationship partners to achieve a high level of involvement with each other and can therefore lead to greater cooperation, intimacy, and compatibility. On the other hand, it provides more opportunities for relationship partners to disrupt each other's interchain activities and can therefore lead to greater conflict, disaffection, and incompatibility. Fortunately,

according to Daniel Wegner, Toni Giuliano, and Paula Hertel, a high level of cognitive interdependence (i.e., shared knowledge and mutual understanding) usually helps to mitigate the potential negative effects of behavioral interdependence, although there are some cases in which partners who understand each other too well can experience greater incompatibility as a result.

Perceptions of Equity and Inequity

Research by Elaine Hatfield and her colleagues has shown that partners strive to be treated equitably within their relationships, and they will often use protests and other means to attempt to gain fairer and more equitable treatment when they feel that they are underbenefited in comparison to their interaction partner. Even when equity is objectively present, however, the erroneous perception that one is underbenefited is generally sufficient to make a previously compatible relationship more incompatible. The other form of perceived inequity—the perception that one is overbenefited in comparison to one's interaction partner—is more easily rationalized and is therefore less likely to affect the compatibility of the relationship unless one's partner perceives and objects to one's overbenefited status.

Perceptions of Relationship Type: Exchange Versus Communal

Margaret Clark and her colleagues have drawn a sharp distinction between exchange relationships and communal relationships. In exchange (i.e., nonintimate) relationships, people regard their treatment as equitable when members follow an implicit tit for tat reciprocity rule, returning benefits to each other fairly quickly and in kind. In communal (i.e., intimate) relationships, however, people are less likely to keep track of what they are "owed" over the short term and instead expect that if they strive to meet their partner's needs, their partner will strive to meet their own needs over time. Short-term violations of the reciprocity rule are therefore more likely to engender incompatibility in exchange relationships than in communal ones. Feelings of compatibility are also likely to be impaired when one person expects the

relationship to be a communal relationship, but the other person expects it to be an exchange relationship instead.

Fantasy Versus Reality

When partners' perceptions of their relationships are fantasy-based rather than reality-based, feelings of compatibility can be illusory as well. On the other hand, when fantasy-based perceptions of the relationship are discredited, the sudden awareness of incompatibility can be all too vivid and real.

Sex-Role Influences

Contrary to what many people believe, heterosexual relationships between a traditionally masculine man and a traditionally feminine woman are not the most compatible ones. Instead, the results of several studies reviewed by William Ickes reveal that both the men and the women in long-term heterosexual relationships express the highest levels of satisfaction when they are paired with a partner who scores high in psychological femininity (i.e., is caring, nurturing, and emotionally supportive).

Self-Conceptions and Mutual Identity Confirmation

The partners' kind and considerate treatment of each other may not be sufficient to ensure a compatible relationship. In addition, each partner needs to feel that his or her self-conceptions and sense of identity are consistently acknowledged and confirmed in the other partner's response to them. Incompatibility frequently results when this is not the case.

Actual and Assumed Similarity

Compatibility is generally facilitated by the partners' similarity on variables such as age, race/ethnicity, socioeconomic status, level of education, religion, and political orientation. It is also facilitated by their similarity in attitudes, values, and some—but not all—personality traits.

Although the partners' actual similarity on such dimensions is clearly important, there is growing evidence that their perceptions of assumed similarity are of equal or even greater importance. For example, in many studies the degree of assumed similarity in attitudes and values plays a greater role in the partners' reported relationship satisfaction than the level of actual similarity does.

The Role of Compatibility and Incompatibility in Marriage Relationships

Because marital incompatibility is a major cause of divorce, it is also a major focus of marital research and marital therapy. George Levinger and Marilyn Rands have reviewed the topic of marital compatibility and incompatibility, examining in some detail the various causes of marital incompatibility and how couples attempt to deal with them. Levinger and Rands argue that various macrolevel variables (e.g., role complementarity, social network influences) and microlevel variables (e.g., conflict resolution styles) continuously impact the quality of marital relationships beginning at the time of mate selection.

Many researchers have used proxy measures such as marital stability and marital satisfaction to identify various demographic and personality traits that facilitate compatible relationships. The search for optimal trait predictors suggests that those traits having the most direct relevance for personal relationships (e.g., psychological femininity, anxious-avoidant attachment, social individuation, social absorption, and sociosexuality) are better than more abstract and general personality traits (e.g., the Big Five personality dimensions) in predicting marital satisfaction and other compatibility-related outcome measures.

Focusing on the darker side of compatibility, William Follette and Neil Jacobson have reviewed the topic of how marital incompatibility is assessed and treated in the context of marital therapy. Therapy with married couples often emphasizes short-term treatment goals, acute problem reduction, and skills training. Behaviorally based marital treatments, such as Behavioral Marital Therapy, have demonstrated some success in improving the quality of interaction between couples because of their focus on positive behaviors, problem solving,

and communication. Behaviorally based treatments may not be appropriate for all distressed couples, however. Because different types of incompatibility require different types of interventions, there is no single one-size-fits-all approach that can be used to restore compatibility to all troubled marriages.

COMPLEMENTARITY

Within the context of social relationships, the term *complementarity* has two distinct and separate

meanings. Of these two definitions, complementarity most commonly refers to the premise that people tend to seek out other individuals with characteristics that are different yet complementary from their own (a concept sometimes called negative assortative mating). A second definition of complementarity is derived from Interpersonal Theory and refers to the principle that during any dyadic interaction, the behaviors of one person tend to elicit or constrain the behaviors of the other, and vice versa (a concept sometimes called interpersonal complementarity). This entry describes both of these definitions and provides an overview of the research examining complementarity.

Negative Assortative Mating

The notion that people are generally attracted to persons who possess characteristics that are dissimilar from their own is a prominent belief in popular culture and is reflected in the common expression opposites attract. It is thought that such differences are sought because it allows couples to divide tasks and pursue goals that are consistent with each member's personality without much conflict. For example, a couple might experience little conflict if one member is motivated or driven by social rewards (e.g., remembers birthdays, focuses on raising children, etc.) and the other is focused on material rewards (e.g., earning a high income).

Although the notion of complementarity tends to be a common belief among laypersons, research examining assortative mating suggests that people tend to be attracted to others who are similar to themselves. It has been argued that such similarity might be sought because it produces feelings of attachment, fosters a sense of equality, and allows each partner to enhance or reinforce the self-concept of the (similar) other. Research has found that men and women alike have a propensity to desire romantic partners similar to themselves on traits such as extraversion, agreeableness, emotional stability, conscientiousness, and openness to experience. Studies have also found preferences for romantic partners who are similar with respect to certain demographic characteristics such as age, ethnicity, religious background, height, weight, socioeconomic status, values, political orientation, and physical qualities. As noted by David Buss,

and in contrast to the popular definition of complementarity, the notion that people desire homogamy is one of the most replicated findings in human mating research.

Not only have studies suggested that individuals tend to desire a person who is similar (i.e., not complementary) to themselves, but such similarity is also related to relationship quality. Researchers have repeatedly found that similarity between romantic partners on various characteristics (e.g., age, socioeconomic status, personality, etc.) is linked to lower levels of divorce and higher levels of marital quality. Taken together, past research suggests that this kind of complementarity is not often sought in romantic partners nor does it typically lead to satisfying relationships.

Interpersonal Complementarity

Within the context of Interpersonal Theory, the term *complementarity* refers to the principle that an individual's behavior tends to alter the behavior of his or her interaction partner. This implies that interpersonal behaviors carry information regarding how the other should respond, and thus, interpersonal behaviors can encourage or restrain subsequent behavior from others. Although this notion of complementarity seems fairly straightforward, there have been various models presented to define exactly how complementarity occurs. Arguably, the two most common models are Robert Carson's model of complementarity and Jerry Wiggins's model of complementarity. Both of these models utilize the dimensions of warmth and dominance, which are often conceptualized as the primary components of social behavior, in order to define complementarity.

Carson's model of complementarity predicts that dominant or submissive behaviors encourage the opposite behavior in interaction partners (i.e., dominance invites submission, and submission invites dominance), and warm or cold behaviors encourage similar response in interaction partners (i.e., warmth invites warmth, and coldness invites coldness). For example, if person A acts in a warm and dominant manner, the likely response of person B would be to complement this style of behavior by acting in a warm and submissive manner. Wiggins's model applies social exchange theory to

the dimensions of warmth and dominance in order to predict behaviors that are complementary. This definition suggests that every behavior carries with it information that grants or denies status (to the self and to the other) and grants or denies love (to the self and to the other), and a complementarity behavior is its logical match. For example, a dominant behavior tends to grant both status and love to the self but only grants love without status to the other. The complementary behavior would therefore be a warm response, which tends to grant love without status to the self and both love and status to the other.

Past research examining which of these two models best predicts interpersonal behavior has been somewhat mixed. Researchers have found that the videotaped behaviors of randomly paired strangers tend to occur in a manner predicted by Carson's model of complementarity. However, others have suggested that support for Carson's model only occurs along the warmth dimensions (i.e., dominance does not induce submission and vice versa). For example, researchers have found that participants who interacted with a confederate coached to act in either a dominant or warm manner tended to act in a similar manner in regard to warmth, but the dominant behavior of the confederate failed to evoke submission in the participants.

In sum, complementarity is most frequently defined as the contention that people tend to seek out other individuals with characteristics that are different from their own but is also associated with the distinctly different notion that, during any dyadic interaction, the behaviors of both persons tend to elicit or constrain the behaviors of each other.

COMPUTER MATCHING SERVICES

Almost as soon as computers were developed, they were used to match people for romantic relationships. The first widespread computer matching service was Operation Match, which was created in the mid-1960s by Harvard students in response to what they believed to be the evils of blind dates and mixers. They recruited students from several universities, charged them each \$3, and had them complete self-ratings of looks, intelligence, and other factors. However, their computer was not powerful enough to process all of the data, and the business failed.

Computer matching was also used on university campuses in the 1960s and 1970s for the purpose of academic research on attraction. For example, in a classic study on attraction (sometimes referred to as the computer dance study), Elaine Hatfield (then Walster) and her colleagues matched incoming freshmen at the University of Minnesota for a night of dancing and, at intermission, had them complete a questionnaire about how much they liked their assigned date. A computer was used to assist with the matching of the freshmen for the dance, but the assistance was very basic: The computer generated random numbers for determining who should be assigned to whom for the date.

Over time, computers became faster, more powerful, more widespread, and small enough to be able to be placed on one's desktop. Then, the high-speed Internet was created. With these technological advances, a new generation of computer matching services was created, known as Internet matching services, online dating Web sites, and the Internet dating industry. Match.com was the first such site, launched in 1995. Currently, there are hundreds of computer matching services available on the Internet, some of them charging users a

monthly fee and some of them free, generating revenue through advertising. Some sites are broad-based and open to the general population of singles, and some sites are focused on a specific type of membership (e.g., jdate.com, GayWired.com, Silversingles.com, FarmersOnly.com) or location (e.g., LonghornSingles.com at the University of Texas). This entry discusses public attitudes about Internet (computer) matching services as a way to meet partners, how common it is for singles to meet partners through these matching services and who uses them, how the matching process occurs, and the interface between computer matching services and the science of relationships. Online dating is a more general term to refer not only to meeting partners through Internet matching services but also to forming relationships in a variety of ways through the Internet, including chat rooms and social network sites.

Public Attitudes About Computer Matching

When Internet matching services first came into existence, the general public impression was negative, at least according to anecdotal evidence such as newspaper articles. One common impression was that people who used such sites were lonely and desperate. Public attention was also focused on those who lied about their marital status or gender, as well as on sexual predators who used the Internet to obtain victims. There is no doubt that deception and sexual predators existed then, and continue to exist today, on Internet dating sites. However, now that meeting partners through Internet matching sites has become more mainstream, attitudes have shifted from being mostly negative to being mixed or positive.

In 2006, the Pew Internet and American Life Project, a nonprofit research center that monitors the social effects of the Internet, conducted a study to examine Americans' attitudes and experiences with online dating. The 70 percent of the sample who were Internet users were asked questions about their attitudes about online dating. Internet users were divided about whether online dating is a good way to meet people (44 percent agreed, but 44 percent disagreed). More agreed than disagreed with a statement, "Online dating allows people to find a better match for themselves because they get

to know a lot more people." Their findings indicated that people no longer believe that those who engage in online dating are desperate, but a majority worried that online dating can be dangerous. Single persons, and especially those who had tried online dating, had more positive attitudes about online dating as a way to meet a partner.

How Many Use Computer Matching Services to Find Partners

There are many statistics that could be considered, if they were available, to address the popularity of computer matching services: (a) the number of people (or proportion of singles) who are members of one or more dating sites, (b) the number of people (or proportion of singles) who dated someone they met through a matching site, and (c) the number of successful relationships (e.g., marriages) that result from Internet matching services. Unfortunately, there is no valid data source for determining these numbers or proportions in the United States or worldwide. However, three types of data suggest how common it is for people to meet others through computer matching services.

First, there is anecdotal evidence, including popular media and people's awareness of the personal lives of their extended network members. Such data cannot provide precise estimates but do give an idea of how common or rare a phenomenon is. Journalists write about online dating, including estimates of the amount of revenue it generates (\$900 million in 2007, according to Jupiter research) and how mainstream it is becoming. As one example, a recent news story discussed the number of weddings announced in *The New York Times* "Sunday Styles" section that included couples who met through one of the major dating sites. However, anecdotal data can lead to overestimates because of what is called the base-rate fallacy. People are likely to remember vivid and unique cases (their aunt's relationship with an eHarmony match) rather than actual base-rate statistics.

Second, one can look at data provided at the matching sites or in their press releases. Match.com claims on their site (as of spring 2008) that they serve 15 million singles in 37 countries and

“every year, hundreds of thousands of people find love at match.com.” eHarmony claims 5 million users, and a press release in 2006 claimed that over 90 singles marry each day on average from an eHarmony match (based on data from a Harris Interactive study conducted in 2005 in the United States); this would translate to 16,425 weddings a year. A caveat is in order, however. Businesses try to present themselves in the best possible light in order to attract more paying customers, and furthermore, they do not have a perfect way of tracking how many of their users go on dates or eventually marry. Therefore, any claims they make on their Web sites about number of matches can only be estimates.

The third, and best source of data, would be based on scientific studies conducted with representative samples. The Pew Internet and American Life Project on online dating, referred to above, found that only about 3 percent reported meeting their current partner through the Internet (more common was to meet through work, school, or family and friends). However, of the single Internet users seeking a partner, 37 percent reported having gone to a dating Web site or other online location to meet people. Fifteen percent of the respondents knew of someone who was in a marriage or long-term relationship with a partner they had met online, and 31 percent knew of someone who had at least tried online dating. Another study was conducted by the Harris Interactive Research center with a national sample. They reported that 3 percent of their respondents indicated having met their partner through an online dating service. Another 3 percent indicated having met their partner through an online chat room, but the most common ways of meeting a partner were at work, in school, and through friends.

Not all single adults are equally likely to use computer matching services to find a partner. The Pew study reported that the percentage of people visiting dating Web sites is higher for males than for females (although the sex ratio varies across the matching services, according to other reports), for urbanites as compared to suburbanites and those in rural areas, and among those in young to middle-adult age as compared to older adults. They also found that online daters were more liberal on social attitudes than nonusers.

The Process of Making a Match

Computer matching services facilitate matching in a number of ways, although the major way that the sites can be distinguished is by whether they offer member searching only or focus on expert matching decisions. Most sites, including the first to develop (e.g., Match.com), facilitate matching by allowing members to post profile information and search the profiles of others. Profile information can include vital demographic information (e.g., age and gender), education, likes and dislikes, and usually a photograph. To assist members in finding the most compatible matches, most sites offer both geographical searches and keyword searches. Dating sites have added many additional features over time, including preprogrammed icebreaker messages, voice and video greetings, anonymous instant messaging and e-mails, relationship advice, message boards, and personality testing.

In 2000, Neil Clark Warren launched an alternative commercial matching Web site, eHarmony.com, followed by perfectmatch.com in 2002 and Chemistry.com in 2005. These sites distinguish themselves by using a “scientific” approach to matching. Members complete a lengthy questionnaire that focuses on personality traits, interests, preferences in a partner, values, and traits that one would not be able to tolerate in a partner. Based on the information provided in these questionnaires (and a monthly fee), the site sends members compatibility matches and a procedure to begin communicating. Matching formulas are supposedly based on scientific principles and translated into computer programs that can sift through the volumes of data collected from members. Dating Web sites have not published their matching formulas or subjected them to peer review, but information on their Web sites and in the media suggests that the focus is mostly on compatibility through similarity, although complementarity (opposites that mesh together well) on some traits and values are also emphasized, particularly at perfectmatch.com. At this stage, there is no evidence as to whether these matches have a greater (or lesser) chance of survival and happiness than matches that originate in more traditional settings.

The Internet matching industry, as well as the technology that interfaces with the matchmaking

Web sites, continues to grow. New developments at matching sites include online speed dating, interfaces of compatibility matching with the social network sites (e.g., *Facebook*), matching through online introductions and votes from friends, and virtual dating. Virtual dating allows individuals to interact with each other in a virtual environment through the use of avatars that can be placed in dating scenarios, such as in a coffeehouse or lounge.

Regardless of the type of computer matching site in which two people learn about each other and engage in initial communication, if there is online attraction and rapport, the two may move their relationship offline—a progression that usually begins with phone calls and then on to a face-to-face meeting in a safe, public place. Many people may have an attraction online only to be disappointed when meeting in person. People who are serious about finding a partner through computer matching services are likely to meet several matches before becoming involved with one.

The Interface Between Computer Matching Services and Relationship Science

Many years ago, relationship researchers studied the attraction process in the commercial matching services that existed at the time—for example, personal want ads and video dating services. They studied the factors that lead to attraction and the choices made in such settings. Scientists are now studying relationship initiation and attraction at the matching sites. Academic published articles are beginning to appear based on data collected from users of matching services and have examined a number of issues including what people seek in a partner, how people present themselves, who is seeking whom, and how the initiation process occurs.

In addition, some of the matching sites invest in research, both proprietary research (for product development) and basic research (to further general science about relationships). eHarmony.com is the current leader in this regard. They have a research organization, eHarmonyLabs, which includes a research laboratory and several scientists devoted to conducting research on the initiation, growth, and maintenance of personal relationships.

COMPUTER-MEDIATED COMMUNICATION

Computer-mediated communication is the domain of human communication in which individuals and groups interact, form impressions, establish relationships, and accomplish tasks using networked computers. Although the timing and stylistic features of communication often distinguish online from offline relationship development and

management, people can initiate relationships, establish effective groups, and develop personal partnerships using computer systems.

Generally speaking, people interacting on computers have access to fewer nonverbal cues than those who interact in person. Although early research predicted that people would not be able to form meaningful relationships using computer-mediated communication, subsequent studies have demonstrated that relational communication is indeed amenable to online interaction. Because there are fewer nonverbal cues available to people who are interacting on computers, it typically takes longer for people to achieve their interpersonal goals than when they interact on a face-to-face basis. Malcolm Parks provides a useful metaphor for understanding this aspect of computer-mediated communication: Interpersonal interaction via computers is a garden hose. Interpersonal information can flow like water through the hose and fill a container (an interpersonal impression) just as well as can a large fire hose; it just takes longer with the smaller hose. Since the language and timing of written messages exchanged via computer systems convey all the social information, with no additional matter relayed by nonverbal behavior, it takes longer for people interacting on computers to accrue sufficient social information with which to form and transmit impressions and affective influence statements.

In some cases individuals form more positive impressions of others via computer-mediated communication than they would form had they had a face-to-face conversation. This phenomenon is known as *hyperpersonal communication*. The nature of computer-mediated communication contributes to the phenomenon of hyperpersonal effects. One characteristic is that computer-mediated communication allows people to carefully select the ways that they present themselves. For example, college students may carefully edit their grammar when they interact with their professors on the computer so that their professors will infer that they are bright and conscientious. Also, because people are not located in the same place during computer-mediated communication and cannot observe their partners' normal appearance and traits, people idealize their partners' characteristics. For example, a couple who met on an online dating site and had their first interactions online may overattribute the similarity and

attractiveness of their partners. Computer-mediated communication also allows users to craft their messages quite deliberately and edit them to fit their desired self- and partner-oriented stereotypes and communication goals. Computer-mediated communication is also hypothesized to foster mutual influence of idealizing responses so that users come to act in ways consistent with the desires their communication partners envision of them. Hyperpersonal communication tends to occur quickly when people plan to have ongoing interaction with others.

One feature that is common in some computer-mediated communication settings is anonymous communication. Anonymous communication occurs when people communicate with one another without knowing the specific personal identities of those with whom they are interacting. When people are anonymous in computer-mediated groups, they tend to be influenced by group dynamics more strongly than they otherwise would. Researchers believe that this occurs when people are relating to others and thinking of themselves as members of social groups or categories as opposed to operating as if they were unique individuals. This has the effect of causing people in computer-mediated groups to exhibit behavior that is consistent with group norms. This effect is particularly strong when there is another group, an outgroup, which members implicitly reject. The effect of group norms has been used to explain the occasional occurrence of flaming in online groups, that is, the contagious reciprocation of insults and profanities. Early research claimed that this kind of misbehavior was a result of the lack of nonverbal cues in computer-mediated communication, and individuals' inability to assess situational norms when they were online. Group identification research provides a better account of flaming, however: When it appears in some groups, it is reciprocated and becomes normative for that group. This is why flaming is not endemic to all computer-mediated communication: It is a function of local group norms exacerbated by anonymity, and not a function of online communication per se. Researchers continue to try to uncover what makes people using computer-mediated communication sometimes remain anonymous and rely on group norms to guide their behavior, while other times people seek and reveal unique information about themselves and interact on a personal level.

As new technologies develop, innovations allow people to interact with others across multiple communication channels. Research is beginning to focus on mixed-mode relationships in which people interact via computers, other media, and in person. Often this occurs when people meet by way of the Internet and continue their relationship through other telecommunications, leading to face-to-face interaction. This progression is typical when people utilize online dating Web sites to meet and establish relationships with potential romantic partners, but it is also common for spontaneous friendships that develop in Internet discussions that are not romantically oriented. An important issue for these mixed-mode relationships is whether people judge the information their partners present about themselves as truthful. Indeed, some research shows that people becoming involved in romantic relationships seek more information about their potential romantic partners than people who are simply friends with one another. Current research is exploring the characteristics of personal information about online acquaintances which make it either more or less believable. It appears that information is more believable when the person it describes is unlikely to be able to create or manipulate it.

New technologies also support mixed-mode relationships that began offline. Social networking technologies such as *Facebook* and *MySpace* allow friends to carry on relationships that move between online and offline venues. Social networking technologies also help people to stay in touch easily with larger networks of acquaintances. These technologies have allowed people who were once out of touch to reconnect easily with one another and continue their relationships online. They are a vital tool for relational maintenance.

CONFLICT, FAMILY

Family conflict is best understood as a particular type of interpersonal conflict that greatly affects the psychological and physical well-being of family members. This entry first defines family conflict and then discusses the frequency and intensity of conflict and ways in which family conflict can be categorized in terms of behaviors and outcomes. Then, the sources and functions of family conflict are reviewed before the entry concludes with a look at the outcomes of family conflict.

Defining Family Conflict

In the most basic way, family conflict can be defined as interpersonal conflict experienced in familial relationships. This means that it is a special case of interpersonal conflict. It is interpersonal because it takes place between individuals who are fully aware of one another and who are interdependent. Like other types of interpersonal conflict, it has both psychological and behavioral attributes. At the psychological level, family conflict exists whenever a family member pursues a goal and perceives another member to be interfering with achieving that goal. At the behavioral level, family conflict occurs whenever a family member engages in outward behavior directed at reducing or removing the perceived interference.

Such behavior may range from an indirect request, such as simply stating one's desires (e.g., "I'd love to go to that party"), to acts of physical coercion (e.g., battering a spouse), and they can be directed at the interfering family member or a third party (e.g., a child anticipating a "no" from the mother might go to the father first).

Family conflict is different from other types of interpersonal conflict for several reasons. First, family relationships are usually involuntary—that is, relationships exist and are maintained regardless of how rewarding or satisfying they are, meaning that they are also enduring and full of personal history. Second, family relationships are embedded within family systems, meaning that they affect and are affected by other interpersonal relationships within the family. For example, a conflict between siblings affects not only their relationship, but also one sibling's relationship with another sibling or the relationship between the parents. Finally, family relationships exist within a cultural context that defines a specific set of expectations, rules, and values for family relationships that are different from other interpersonal relationships. For example, in North America, compared with other interpersonal relationships, family relationships are affectionate, less private, and more physically violent (e.g., spanking).

Frequency and Intensity of Conflict

Of all interpersonal relationships, family relationships are the most conflicted because of both the greater intimacy of family relationships and the greater interdependence of family members. Greater intimacy leads to more conflict because it is associated with more directness in communication, an increased sense that one has the right to make requests of the other, and increased expectations that the other will comply with one's request. Greater interdependence leads to more conflict because being dependent on others means that they are more likely to be able to interfere with goal achievement and to be perceived as interfering.

Research has not been able to establish the frequency of family conflict, mainly because different researchers use somewhat different definitions and operationalizations of conflict, but there can be no doubt that it constitutes a substantial proportion

of family communication. Particularly, when using the definition proposed in this entry, arguably most interactions involving parenting could be defined as conflict.

As far as conflict intensity is concerned, there can be little doubt that conflict is most intense in family relationships. Whereas few would engage in or tolerate physical violence in conflicts at work or with friends, family relationships are rife with violent conflict. In representative samples of the U.S. population, for example, Murray Straus found severe violence (including kicking, punching, and attacks with objects) occurring in at least 8 percent of all marital relationships, 11 percent of parent-child relationships, and 36 percent of sibling relationships. Less severe violence (e.g., shoving, pushing, and slapping) occurs in around 16 percent of marriages, in almost 100 percent of parent-child relationships with young children (age <3 years), in 34 percent of parent-child relationships with adolescents, and in 64 percent of sibling relationships.

Types of Conflict

Because family conflict is so pervasive and includes such a wide range of behaviors, it is very difficult for researchers to make any statement about it that applies to all family conflict. One way to address this problem is to categorize conflict into different types that are defined specifically and about which theoretical statements can be made. Because most scholars interested in human relationships care about what happens between people rather than in the heads of individuals, most of these typologies either are oriented toward relational outcomes of conflict or toward observable behaviors, sometimes in combination with the likely outcomes of these behaviors.

One way to distinguish between different types of family conflict is to focus on the relational outcomes of conflict behaviors and to label them accordingly as either functional (i.e., constructive) or as dysfunctional (i.e., destructive). Such a distinction is meaningful as long as it can be assumed that there are conflict behaviors that fairly consistently lead to positive outcomes and those that lead to negative outcomes. Distinguishing between constructive and destructive conflict behaviors is often motivated by the desire of the researchers to

identify and teach “good” conflict communication skills. As the voluminous number of “how to” manuals attests, this research has proven very fruitful and has certainly captured the public imagination.

Such typologies, however, are not without problems. Not only is the meaning of conflict behavior inherently ambiguous, but also the standards by which conflict behavior is judged as either constructive or destructive are often impossible to define objectively. Whereas it is relatively easy to make theoretical distinctions that employ fairly abstract concepts such as “interest versus needs centered” and “bolstering versus compromising interdependence,” judging concrete behaviors using the same abstract concepts is much more difficult.

In addition, it is not entirely possible to separate the relational outcomes of conflict from its practical outcomes for individuals. Although process does matter, persons’ relationship commitment and satisfaction is at least partially dependent on the extent to which they are able to obtain desired outcomes from their interpersonal relationships. Thus, whether conflict is ultimately constructive depends on whether conflict is judged using a long- or short-term perspective; whether these outcomes are psychological, behavioral, or relational; and finally, from whose perspective the outcomes are judged. Because at the root of many family conflicts are incompatible goals or interests of family members, it is almost inevitable that any outcome has to be evaluated differently depending on whose perspective is used when making the evaluation. Thus, conflict behavior that achieves a desired outcome for one family member (and from that person’s perspective is functional) might be dysfunctional for another. Even relational outcomes are not necessarily perceived the same by all parties in a family.

An alternative way of classifying conflict behaviors is to focus on the behaviors themselves, rather than their outcomes. Exclusively behavioral typologies group certain types of conflict behaviors together, usually distinguishing between different types of behavior along some underlying dimension, such as intensity. For example, one popular typology distinguishes between latent conflict, problem to solve, dispute, and fight. Similarly, Straus identified three types of conflict behaviors: reasoning, which refers to rational discussion and

problem-solving behaviors; verbal aggression, which refers to behavior symbolically hurting the other; and violence, which refers to behavior inflicting physical pain and/or injury.

A number of other conflict typologies proposed by researchers categorize conflict behaviors into four types based on two underlying dimensions. Despite various labels for the types and dimensions, they are conceptually very similar, and the dimensions can be generically described as direct versus indirect communication and cooperation versus competition. The four resulting types can generically be called negotiation-collaboration (direct and cooperative), which includes behaviors such as agreement, analytic remarks, metacommunication, description, expressing, problem solving, summarizing, and validating; fighting-argument (direct and competitive), which includes behaviors such as blaming, coercive acts, confrontation, disagreement, invalidation, and rejecting acts; nonconfrontation-accommodation (indirect and cooperative), which includes behaviors such as facilitation, irrelevant remarks, resolving acts, and topic management; and passive aggressive-obstruction (indirect and competitive), which includes behaviors such as denial, equivocation, and withdrawal.

Sources of Family Conflict

The number of actual and perceived goal incompatibilities between family members that are at the root of family conflict depend on goals that vary by individuals and families and therefore are both infinite and unpredictable, as are their sources. There are, however, a number of fairly normative and therefore predictable goal incompatibilities between family members that make certain kinds of family conflict both common and predictable. Ignoring conflict between spouses (dealt with in a different entry in this encyclopedia), conflict between parents and children, and between siblings is typical for families and contributes significantly to children’s cognitive and social development.

Conflict between parents and preadolescent children most typically involves parents’ attempts to regulate their children’s behavior and children initially resisting and ultimately complying with the demands of their parents. That is, conflict is a

natural part of the socialization process as children move from other-regulation to self-regulation, and such instances constitute much of family communication. Thus, one would expect the frequency of family conflict to decrease as children mature and become more self-regulated. This expectation is supported by data showing parents' use of physical punishment decreasing as children get older.

Whereas conflict frequency decreases as children mature, families often perceive an increase in the intensity of family conflict as children reach adolescence. This apparent contradiction occurs because the very nature of the parent-child relationship is changing during adolescence, which makes parent-child conflict more salient to family members during adolescence. In relationships involving younger children, both parents and children understand their relationship as one in which parents provide guidance and discipline. Thus, both parents and children expect to have conflicts with one another and see conflict as an integral and therefore not necessarily salient aspect of their relationship. As a consequence, both parents and children may perceive their relationship to be relatively free of intense conflict, even though much of their communication consists of parents regulating their children's behavior, which could objectively be defined as conflict.

Adolescents, in contrast, tend to see themselves as much more autonomous and independent in their relationships with their parents and increasingly come to resist the regulating behavior of their parents. For them, resistance to the parents often becomes an end in itself, while parents try to maintain some influence over their children. Thus, even though parents objectively regulate their children's behavior less frequently, the influence that parents exert over their adolescent children becomes the underlying relational issue that manifests itself in overt conflict, making these conflicts more intense and both parents and adolescents more aware that they do experience conflict in their relationships.

Functions of Family Conflict

Not only is family conflict an inevitable part of family relationships, but also it serves important functions for the family as a whole and for individual family members. As systems of interdependent

individuals whose goals, interests, and needs are not always in alignment and often in direct opposition, families must find ways to respond to such incompatibilities in ways that maintains the system overall. Because it is impossible for family members to anticipate each other's interests, desires, and emotional states without communicating about them, only expressed conflict allows family members to address and resolve their divergent goals. Thus, the most important function of family conflict is to allow families to recognize the needs of individual family members and to coordinate their behaviors so that they can facilitate goal achievement for their members while simultaneously maintaining the family system.

Probably the second most important function of family conflict is to facilitate the socialization and development of children. Specifically, family communication serves five developmental functions for adolescents, all of which are mainly achieved through conflict. The functions are renegotiation of roles, rules, and relationships; identity exploration; enhancing adolescents' self-esteem; modeling and teaching problem-solving behaviors; and enabling adolescents' decision making.

Almost by definition, these functions involve family conflict. For example, it is hard to imagine that renegotiations of parent-adolescent relationships, and the rules that accompany them, can be accomplished without expressed conflict. In fact, the renegotiation of roles explicitly involves a change in the power relationship from relative dependence to relative independence of the adolescents. Adolescents usually aim for greater independence, and the parents usually aim to maintain the status quo. Because both parents and children are heavily invested in their respective goals, these conflicts are not easily resolved and are often quite emotional. Similarly, for parents to teach and to model conflict behaviors and to teach decision-making skills requires them to engage in family conflict and decision making. It is an old adage that children learn more from what parents do than from what parents say, and conflict communication is no exception. Although less obviously related to conflict, the functions of helping adolescents explore their identities and enhancing their self-esteem also are related to family conflict. Exploring identities almost invariably involves adolescents' taking positions and espousing opinions and values that

differentiate them from other family members and, particularly, from their parents. Doing so successfully enhances self-esteem.

Outcomes of Family Conflict

Family relationships and family communication interest researchers, counselors, and laypeople because for most adults and children, family relationships are their most important and most intimate interpersonal relationships. In addition, families are children's main socialization agents, and the communication and relationship skills that children acquire in their families of origin affect the quality of their interpersonal relationships throughout their lifetime. All these reasons that justify an interest in family communication in general also justify an interest in family conflict communication in particular. How persons communicate during family conflict is of paramount relevance in determining the quality and stability of their family relationships.

Married couples who manage interpersonal conflict well in their relationships report greater relationship satisfaction, more love and respect for their partners, and greater commitment to their partners and are less likely to get divorced. Similar findings are reported for other family relationships. Families that manage their conflicts well have more satisfied parents and children, and children perform better in school and in peer relationships. Thus, family conflict is an important determinant of relationship quality and quality of life of family members. In addition, because of the family's central role in socializing children, the conflict behaviors children learn in their families of origin affect their subsequent interpersonal relationships as adults. Finally, physical violence and child abuse greatly affect the mental and physical health of children and are more likely to occur during family conflict than during any other time of family communication.

Ignoring the research on marital conflict, which is discussed in a different entry of this encyclopedia, most research on the consequences of family conflict has investigated the outcomes for children. Generally speaking, to the extent that families engage in conflict that is destructive, hostile, or even violent, family conflict is associated with

negative outcomes for children. In contrast, to the extent that families engage in constructive conflict, such as rational conflict and conflict focused on problem solving, family conflict is associated with positive outcomes for children in general and for adolescents in particular. Young children who are exposed to intense, destructive parental conflict experience fear, sadness, and anger and feel unsafe and insecure in the home and outside the family. In addition to negative psychological outcomes, children of families that frequently engage in destructive conflict also experience problems in their peer relationships. Intense parental conflict is associated with children's greater aggression and anger in relationships with teachers, peers, and siblings.

There are several processes by which parental conflict causes these negative outcomes for children. One explanation for the psychological and social effects is that important security needs that children have in their relationships with their parents are unmet when parents have frequent conflict among themselves or with their children, particularly if these conflicts involve verbal aggression or physical violence. The negative psychological consequences that children exhibit are the result of these unmet needs. The social effects, by contrast, are the result of poor parental modeling of communication skills that leads children to behave poorly in their interpersonal relationships with others.

Similar processes are responsible for the positive outcomes children experience when exposed to constructive parental conflict behavior. These children benefit both psychologically and socially from their parents' problem-solving skills. Because children experience safety and security in their relationships with parents, they are psychologically better adapted, have higher self-esteem, and perceive the world to be a friendlier and less threatening place than children of families where parents model poor conflict communication. In regard to social outcomes, the conflict styles they learned from their parents help these children manage their relationships with their siblings and peers more successfully than children of families with poor parental modeling.

Compared to the interest in outcomes for children, there is very little research interest in parents as victims of family conflict, and therefore, the knowledge of how parents are affected by family conflict is limited indeed. One would think that high

frequency and negativity of family conflict would lead to similar reductions in relationship satisfaction and related psychological outcomes as conflict in the marital relationship. There is, however, almost no empirical evidence available supporting this assumption. Clearly, this is an area where future research will have to provide the answers.

CONFLICT, MARITAL

Marital conflict refers to overt opposition between spouses that is identified by the spouses as disagreement or a source of difficulty in the relationship. Couples complain about sources of conflict ranging from verbal and physical abusiveness to personal characteristics and behaviors. Perceived inequity in a couple's division of labor also is associated with marital conflict and with a tendency for the male to withdraw in response to conflict on this topic. Conflict over power is strongly related to marital dissatisfaction. Finally, conflicts relating to extramarital sex, problem drinking, and drug use have been shown to predict divorce.

Implications of Conflict

Conflict between spouses is among the most frequently investigated topics in marital research, and this research focus is understandable given its implications for mental, physical, and family health. Marital conflict has been linked to the onset of depressive symptoms, anxiety disorders, eating disorders, episodic drinking, binge drinking, out-of-home drinking, and male alcoholism. Although married individuals are healthier on average than the unmarried, marital conflict is associated with poorer health and with specific illnesses such as cancer, cardiac disease, and chronic pain perhaps because hostile behaviors during conflict are related to alterations in immunological, endocrine, and cardiovascular functioning. Physical aggression occurs in about 30 percent of married couples in the United States, leading to significant physical injury in about 10 percent of

couples. Marriage is also the most common interpersonal context for homicide, with more women being murdered by their partners than by anyone else. Finally, marital conflict is associated with important family outcomes, including poor parenting, poor adjustment of children, increased likelihood of parent-child conflict, and conflict between siblings. Marital conflicts that are frequent, intense, physical, unresolved, and child-related have a particularly negative influence on children.

Behavior During Conflict

Much of the research on marital conflict has been motivated by the goal of helping couples to deal effectively with conflict. This research has focused on the observation of discussions in the laboratory where couples are asked to try and resolve a problem in the relationship. Typically, couples also complete an inventory assessing marital quality (e.g., Dyadic Adjustment Scale, DAS) and those scoring below the cutoff for marital distress (DAS score <97) are compared to nondistressed couples. Using these methods, researchers have provided detailed information about how marital distressed and nondistressed couples behave during conflict.

During conflict, distressed couples make more negative statements and fewer positive statements than nondistressed couples. They also are more likely to respond with negative behavior (e.g., put downs, whining) when their partner behaves negatively. Indeed, this negative reciprocity, as it is called, is more consistent across different types of situations than is the amount of negative behavior, making it the most reliable overt signature of marital distress. Negative behavior is both more frequent and more frequently reciprocated in couples who engage in physical aggression than in other couples. Nonverbal behavior (e.g., posture, gaze aversion, voice tone), often used as an index of emotion, reflects marital satisfaction better than verbal behavior and, unlike verbal behavior, does not change when spouses are asked to try to fake good and bad-distressed marriages in the laboratory.

In some research studies, couples have been asked to keep daily records of positive and negative behaviors. Daily negative behaviors predict

variability in day-to-day marital satisfaction. That is, on days when there are more negative behaviors reported, marital satisfaction is lower. The association between behaviors recorded and marital satisfaction is stronger for distressed than for nondistressed spouses. Overall, the data from diary studies yield findings that are very similar to those obtained in the laboratory and described above. In both laboratory and diary studies, negative spouse behavior accounts for approximately 25 percent of the variability in the spouse's marital satisfaction. Among newlyweds, wives' reports of husbands' negative behaviors predict wives' satisfaction with the marriage 2 years later.

Although direct observation of conflict that takes the form of physical aggression (ranging from slapping the partner to use of a weapon) in marriage is not possible, studies have been conducted on interactional styles in violent and nonviolent marriages. Even when compared to distressed couples who are not violent, for example, the interactions of distressed violent couples are marked by higher levels of negative reciprocity, anger, and contempt. Alcohol use is associated with increased levels of physical aggression. Surprisingly, a few studies find that some form of physical aggression is present in a majority of newlywed marriages, and both physical and psychological aggression predicts divorce among newlyweds.

Patterns of Conflict Behavior

The sequences of behavior that occur during conflict are more predictable in distressed than in nondistressed marriages and are often dominated by chains of negative behavior that usually escalate and are difficult for the couple to stop. One of the greatest challenges for couples locked into negative exchanges is to find an adaptive way of exiting from such cycles. Couples usually try to get out of the negative exchanges with responses designed to repair the interaction (e.g., "You're not listening to me"), but these exchanges are delivered with negative affect (e.g., irritation, sadness). The partners tend to respond to the negative affect, thereby continuing the cycle. This cycle makes their interactions structured and predictable. In contrast, nondistressed couples appear to be more responsive

to attempts at repair and are thereby able to exit from negative exchanges early on. For example, a spouse may respond to "Wait, you're not letting me finish" with "Sorry, please finish what you were saying." Their interaction, therefore, appears more random and less predictable.

A second important conflict behavior pattern exhibited by marital distressed couples is the demand-withdraw pattern in which one spouse pressures the other with demands, complaints, and criticisms, while the partner withdraws with defensiveness and passive inaction. Specifically, behavior sequences in which the husband withdraws and the wife responds with hostility are more common in distressed than in satisfied couples. This finding is consistent with several studies showing that wives display more negative affect and behavior than husbands, who tend to not respond or to make statements suggestive of withdrawal, such as irrelevant comments. Disengagement or withdrawal is, in turn, related to later decreases in marital satisfaction. However, inferring reliable gender differences in demand-withdraw patterns would be premature, as recent research shows that the partner who withdraws varies according to which partner desires change. So, for example, when a man desires change, the woman is the one who tends to withdraw.

It is noteworthy that neither distressed nor non-distressed spouses reciprocate positive behavior. This finding challenges the widespread view that satisfied couples are characterized by a *quid pro quo* that involves the exchange of positive behaviors. Instead, they are better described as behaving according to a bank account principle to the extent that they expect positive behaviors to be reciprocated; the reciprocation occurs over the long term.

Does marital conflict studied in the artificial setting of the laboratory capture what happens in the real world outside the laboratory? Couples who participate in laboratory studies report that their interactions in the laboratory are reminiscent of their typical interactions. Research also shows that conflict behavior in the laboratory is similar to conflict behavior observed in the home; however, laboratory conflicts tend to be less severe, suggesting that research findings underestimate differences between distressed and nondistressed couples.

Is There a Simple Way to Summarize Research on Marital Conflict?

One way to summarize the extensive literature on marital conflict behavior is in terms of a simple ratio. For happy couples, the ratio of agreements or positive behaviors to disagreements or negative behaviors is greater than one, and for unhappy couples, it is less than one. John Gottman identifies this ratio more precisely for what he calls regulated and nonregulated couples. These couples were identified by calculating for each spouse the cumulative difference between positive and negative behaviors across the course of an interaction. Using the patterns in these difference scores, he distinguished regulated couples (increase in positive speaker behaviors relative to negative behaviors for both spouses over the course of conversation) from nonregulated couples (all other patterns). Regulated couples displayed positive problem-solving behaviors and positive affect approximately 5 times as often as negative problem-solving behaviors and negative affect, whereas the corresponding ratio was approximately 1:1 for nonregulated couples. This distinction is important because regulated couples, compared to nonregulated couples, were more satisfied in their marriage and were less likely to divorce.

In sum, marital satisfaction and marital stability does not reflect the absence of marital conflict but rather a relatively higher level of positive behavior compared to negative conflict behaviors. Concretely illustrating this point is the finding that the ratio of sexual intercourse to arguments, rather than their base rates, predicts marital satisfaction.

Intrapersonal Processes Related to Conflict

Beginning in the 1980s, recognition emerged that a purely behavioral account of conflict was limited and gave rise to the study of intrapersonal variables such as thoughts and feelings that might give rise to and maintain conflict behavior.

Thinking

In regard to interpretations or thoughts about conflict, researchers have focused on two questions presumed to arise regarding relationship

conflict: “Why is the conflict occurring?” and “What can I do to resolve the conflict?” The first question has to do with the attributions for the conflict, and the second deals with efficacy expectations or the extent to which a spouse believes that he or she can perform the behaviors necessary to resolve the conflict.

In regard to attributions, it is argued that explanations inferred for partner conflict behavior determine responses to the behavior. Certain kinds of explanations tend to promote conflict. For example, a spouse inferring that his or her partner’s critical comment was meant to be destructive (e.g., “She is trying to embarrass me”) rather than constructive (e.g., “She is trying to help me create a good impression”) is more likely to respond negatively to the comment. Consistent with this view, it is well established that conflict-promoting attributions are related to negative affects that occur during conflict interactions, especially anger and whining, rates of negative behavior, the effectiveness of problem-solving attempts, and the reciprocation of negative partner behavior. These relationships are stronger in distressed spouses than in nondistressed spouses. Finally, conflict-promoting attributions for marital problems have been associated with more negative conflict behavior over a 12-month period.

In a similar vein, a spouse’s belief that he or she can perform the behaviors necessary to resolve the conflict predicts his or her conflict behavior. When these efficacy expectations are stronger, higher rates of positive behavior during conflict are observed. Stronger efficacy expectations also predict use of higher-quality problem-solving approaches and observers’ rating of spouses’ satisfaction with conflict resolution attempts.

Feeling

A variety of indices of emotion have been examined in marital research including, as noted earlier, nonverbal behavior that is more powerful than verbal behavior in discriminating satisfied from dissatisfied couples. Other indices of emotion investigated include verbal reports and measures of autonomic nervous system activity such as heart rate. Online measurements of autonomic nervous system activity during the course of low and high conflict discussions show that physiological

interrelatedness (or physiological linkage) between partners occurs at the times when negative affect was reported as occurring and being reciprocated and is higher during high-conflict tasks compared to the low-conflict tasks. Higher physiological interrelatedness also is related to lower marital satisfaction.

From the foregoing, it is clear that intrapersonal processes such as thoughts and feelings are critical in providing a more complete account of marital conflict. Most recently, however, it has become clear that marital conflict can only be understood fully when considered in context, a realization that has emerged from the focus on longitudinal research in the past decade.

Contextualizing Conflict

Conflict behavior and conflict patterns seem to be relatively stable over time and to predict changes in marital satisfaction and marital stability. However, longitudinal findings show that conflict, taken by itself, accounts for a small portion of the variability in later marital outcomes, suggesting that other factors need to be considered in predicting these outcomes. This has led to an increasing interest in how conflict may vary according to contextual factors.

Stressors and Life Events

Diary studies illustrate that couples have more conflictual marital interactions at home on days of high general-life stress than on other days and at times and places where they are experiencing multiple competing demands; arguments at work are related to marital arguments, and the occurrence of stressful life events is associated with more conflictual problem-solving discussions. Ongoing stress, such as financial need or chronic illness, also is associated with marital conflict. Such considerations suggest that conflict may have little impact on a marriage in the absence of external stressors. There is a growing need to identify the stressors and life events that are and are not influential for different couples and for different stages of marriage, to investigate how these events influence conflict, and to clarify how individuals and marriages may inadvertently generate stressful events.

Spousal Support and Affectional Expression

The significance of conflict for marital outcomes also needs to be considered in relation to the occurrence of spouse support and emotional expression. Supportive spouse behaviors are only weakly related to the conflict behaviors observed during the problem-solving discussions used to study marital conflict, but they appear to play an important role in moderating the impact of conflict. The amount of supportive behavior partners exhibit predicts later marital stress (i.e., more supportive behavior correlates with less future marital stress), independently of conflict behavior. When support is low, there is an increased risk that poor skills in dealing with conflict will lead to later marital deterioration. Finally, in the context of high levels of affectional expression between spouses (e.g., saying, "I love you," and expressing physical affection outside of intercourse), the inverse relationship between conflict behavior and marital satisfaction decreases. In regard to conflict patterns, the demand-withdraw pattern is unrelated to marital satisfaction in the context of high affectional expression, but they are highly related in the context of average or low affectional expression. It is therefore apparent that attention to positive spouse behavior is essential for a correct characterization of the role of conflict in marital outcomes.

Spousal Background and Characteristics

Although initially ignored in research on marital conflict, there is increasing evidence that the background and characteristics of individual spouses play an important role in regard to marital conflict. The importance of spouses' backgrounds is illustrated by the finding that divorce is transmitted across generations. Divorce rates are higher for offspring whose parents report low marital conflict prior to the divorce and for offspring who behave in hostile, domineering, and critical ways compared to offspring who do not behave in this manner. Thus, while parental divorce places offspring at risk for marital conflict and divorce, such outcomes are not inevitable.

An individual characteristic that is proving to be particularly informative for understanding marital conflict comes from recent research on attachment,

which aims to address questions about how the experience of relationships early in life affects interpersonal functioning in adulthood. For example, spouses who tend to feel secure in relationships tend to compromise and to take into account both their own and their partner's interests during problem-solving interactions, thus showing low conflict; those who tend to feel anxious or ambivalent in relationships show a greater tendency to oblige their partner and focus on relationship maintenance thereby showing less conflict than do those who tend to avoid intimacy in relationships. And spouses who are preoccupied with being completely emotionally intimate in relationships show an elevated level of marital conflict after an involuntary, brief separation from the partner.

Of particular interest for understanding negative reciprocity are the findings that greater commitment is associated with more constructive, accommodative responses to a partner's negative behavior and that the dispositional tendency to forgive is a predictor of spouses' responses to their partners' transgressions. In other words, spouses who have a greater tendency to forgive are less likely to avoid the partner or to retaliate in kind following a transgression by the partner. Forgiving may be a means of exiting from negative reciprocity as it is associated with later conflict resolution. Indeed, spouses themselves acknowledge that the capacity to seek and grant forgiveness is one of the most important factors contributing to marital longevity and satisfaction. Also relevant to understanding conflict is sanctification, a process whereby the marriage is perceived as having divine character and significance (e.g., "God is present in my marriage" and "My marriage is sacred"). The degree to which a spouse engages in this process is related to greater collaboration in resolving disagreements and less conflict. Importantly, this association is independent of degree of religiosity.

Conclusion

Guided by the view that marital distress results from ineffective handling of conflict, a substantial body of research has emerged on conflict behavior in marriage. Over time, this work was expanded to include intrapersonal processes related to conflict. With the recent attempt to place conflict in context,

there is an emerging consensus that its role in marriage needs to be reconsidered. Also, there is increasing recognition that marital conflict may be more complex than initially thought and that it needs to be accompanied by an understanding of marital strengths if researchers are to gain a more complete understanding of the marital relationship.

CONFLICT MEASUREMENT AND ASSESSMENT

It is common for friends, lovers, and family members to experience conflict from time to time. In an interpersonal relationship, conflict is defined as a situation in which at least one partner dislikes how the other appears to be behaving, thinking,

or feeling. When there is conflict between two people, they may argue, calmly discuss the issue, or avoid the topic altogether. Conflict is a key force that produces change in relationships, for better or worse, and therefore, researchers assess conflict to learn how relationships work. When two people are able to resolve conflict, they often make changes to accommodate each other, gain a better understanding of each other, and experience an increased level of closeness or friendship. When two people fail to resolve conflict, their relationship is likely to deteriorate. This entry describes how researchers assess conflict, the different components of conflict that are typically assessed, and important issues to consider regarding the validity of conflict assessment.

Ways of Assessing Conflict

There are several factors that make assessing conflict a challenge. Although conflict is a normal component of almost any interpersonal relationship, most people do not experience conflict on a daily basis, and when conflict does occur, people often try to keep it hidden from public observation. Therefore, it is especially difficult for researchers to directly observe conflict in a natural environment. Instead, researchers most typically assess conflict by making observations in a structured laboratory setting or by administering questionnaires that ask people to provide a self-report description of their conflict experiences.

Research with married couples has made extensive use of structured laboratory settings to assess conflict, and this method can be easily adapted to assess conflict in a wide variety of relationships. In the typical protocol, a couple visits a research laboratory where they are asked to identify an area of conflict. Partners may be separated and individually asked to describe a recent conflict episode, or they may be given a list and asked to identify issues that cause conflict in their relationship, or a researcher may interview the couple together and identify a common area of conflict. Using one of these techniques, a single area of conflict is selected as a topic for discussion, and the couple is then left alone in a room with instructions to attempt to resolve the issue. Typically, the couple is given 10 to 15 minutes for their conversation, and sometimes,

couples are asked to complete two different conversations, discussing separate topics selected by each partner. With the couple's knowledge and consent, their conversations are video-recorded.

The video-recorded conflicts are scored using one of several possible approaches. Typically, researchers use a coding manual that provides precise definitions for different types of communication behavior. Trained coders then use detailed instructions in the coding manual to assign scores to the conversation. In this approach, it is essential to ensure that ratings are reliable. That is, the scores assigned to any given conversation should not be dependent on who coded it. Reliability can be improved by having each conversation coded by several different coders and also by ensuring that coders receive sufficient training. It is not always necessary, however, to train coders. Recent research has found that untrained coders can actually make reliable ratings regarding the extent to which people express certain basic emotions, such as anger or sadness. Another way to obtain scores is to have a couple rate their own conversation. For example, participants may watch a playback of their conversation and turn a dial in real time to indicate their level of emotion, or they may be asked to identify points in the conversation when a particular type of thought, feeling, or behavior occurred.

Another method of assessing conflict involves self-report questionnaires. In contrast to laboratory assessments, questionnaires are easier to administer to large groups of people and to people across multiple geographic regions. Using questionnaires, it is possible to assess levels of violent behavior during conflict, to assess multiple perspectives of conflict from each member of a family or team, and to assess the private thoughts and feelings people have during times of conflict. Although questionnaires are traditionally printed on paper, it can be both convenient and inexpensive to administer questionnaires using the Internet. In this way, data can be automatically scored and entered, and respondents can receive automatic feedback that might help them improve their conflict resolution skills. Researchers can also assess conflict by using a diary method in which participants report their everyday experiences over several days or weeks. For example, participants may carry a small electronic device to provide reports of current experience at specified or random points throughout each day. In this way,

it is possible to assess both the frequency of conflict and a person's experience during conflict episodes that happen to occur.

Which Components of Conflict Are Important to Assess?

Assessing conflict is complex because conflict contains many different components, and these components can be assessed at varying levels of specificity. Many questionnaires for measuring conflict provide a single score reflecting the overall level of conflict in a relationship. In contrast to this type of global assessment, it is often useful to conduct a more detailed assessment regarding specific components of conflict. For example, there are instruments available for assessing the underlying issues that cause conflict, the extent to which a conflict is resolved, the extent to which children observe different types of conflict between family members, and the extent to which partners use physical violence during conflict. As discussed below, some of the most commonly assessed components of conflict include specific types of communication, emotion, and cognition (or thoughts).

Communication

Most research using structured laboratory settings has focused on assessing ways people communicate during conflict. In this line of study, researchers have developed a number of different coding manuals, which taken together, describe a vast array of communication behaviors. Many behaviors defined in these manuals can be broadly classified as either positive or negative based on whether the communication facilitates or hinders conflict resolution.

There are several types of negative communication. One of the most common is criticism, which includes voicing negative explanations for a partner's behavior, blaming a partner for something, and making accusations about what a partner is thinking, feeling, or wanting. Criticisms frequently begin with the word *you*, and they sometimes involve global or sweeping statements using words such as *always* or *never*. Because criticisms are likely to be perceived as an attack, they frequently

elicit either defensiveness or withdrawal from a partner. In a defensive response, a person attempts to invalidate, trivialize, deny, or refute the perceived attack. When a person withdraws, he or she seeks to escape from conflict by avoiding the partner or by becoming silent and unresponsive. More extreme forms of negative communication include expressions of contempt, where one partner says something hurtful to the other, and domineering behavior, where one partner seeks to threaten or control the other.

Whereas negative communication often involves critical statements about one's partner, positive communication typically involves personal or vulnerable statements about oneself. To resolve a conflict, it is essential for each partner to understand the other's viewpoint, and this is most likely to occur when both partners calmly state their own desires, emotions, opinions, and perspectives and when they demonstrate empathic concern, affection, and understanding for each other. Thus, positive communication generally includes sharing personal information about oneself, carefully listening to one's partner, and making responsive statements that show understanding for one's partner.

Emotion

Research has identified two types of emotion that are especially important to assess during times of conflict, sometimes referred to as hard emotion and soft emotion. Hard emotion includes feeling angry and aggravated, and this type of emotion is associated with asserting power, defending oneself against perceived attacks, and pursuing self-focused objectives. Soft emotion includes feeling sad and hurt, and this type of emotion is associated with expressing vulnerability, seeking social support, and pursuing objectives that strengthen interpersonal relationships. Both emotions are important because they motivate partners to address areas of conflict. However, hard emotion often leads to high levels of negative communication, whereas soft emotion is associated with significantly less negative communication and is often beneficial for helping couples resolve conflict. In addition to hard and soft emotion, people occasionally experience pleasant emotions during times of conflict, such as affection or shared, nonsarcastic humor, and these emotions often facilitate conflict resolution.

Notably, there may be important differences between assessing a single instance of conflict and assessing the ways conflict is typically handled in a relationship, and this is especially true for emotion. Some components of conflict are associated with temporary declines in relationship satisfaction but actually predict long-term improvements in overall relationship quality. For example, a single episode of anger can lead to increased conflict, but in the long term, occasional expressions of mild anger may benefit a relationship, whereas the chronic suppression of anger is likely to be harmful. In contrast to anger, crying during a single episode of conflict may elicit empathy from a partner, whereas crying may elicit only frustration if it is a chronic response to conflict interactions.

Cognition

Cognition involves the thoughts that people think during conflict, and three types of cognition are especially important: attributions, expectancies, and beliefs. Attributions are the explanations people make for a partner's actions. In the case of conflict, attributions include a person's judgments regarding whether his or her partner caused the conflict or should be blamed for the conflict. Expectancies include the predictions a person makes regarding how the other is likely to behave during a conflict. People are more likely to use negative communication when they expect their partners to be negative. Beliefs include the assumptions people make regarding what types of conflict are normal and how people should act during times of conflict.

Conflict in Families

In addition to the components of conflict discussed above, there are unique components of conflict that can be assessed when more than two people are involved, as is the case in family conflict. Using questionnaires, family conflict can be assessed from the perspectives of both adults and children. In structured laboratory settings, families are sometimes observed as they discuss an area of family conflict or as parents instruct their children to clean a messy playroom. Two distinctive components of family conflict include boundaries and

leadership. Boundaries have to do with alliances among family members. For example, a coalition occurs when two people join together against a third person, and triangulation occurs when one person tries to entice or entrap another into forming a coalition against a third. Disengagement occurs when family members have strong boundaries that separate each other, whereas enmeshment occurs when family members lack boundaries altogether. In assessing family conflict, it is also useful to consider parental leadership style. For example, a parent may use a democratic style in which all family members are given opportunities to express their viewpoints and feelings. A parent could also use an autocratic style in which he or she seeks to control and coerce other family members into compliance, or a chaotic style in which the parent fails to provide effective leadership or guidance.

Validity of Conflict Assessment

As with any type of assessment, it is important to demonstrate that the methods used to assess conflict are valid. That is, the methods should accurately measure what they are intended to measure. For example, when an assessment involves the use of self-report questionnaires, there is a risk that people may provide invalid answers because they fail to remember an event accurately, they do not want to acknowledge personal faults, or they view a situation from a one-sided perspective. With married couples, it is common for a wife and husband to give completely different accounts of what actually occurred during a conflict, a tendency which calls into question the validity of their reports. However, the validity of a self-report questionnaire can be supported if research demonstrates that partners' responses to the questionnaire correspond with ratings made by trained coders observing partners' behavior in a laboratory setting.

The validity of a questionnaire can also be threatened by sentiment override, which occurs when a person responds to questionnaire items on the basis of his or her global feelings about the relationship rather than responding to the specific content of the items. For example, a person who is happy and satisfied in a relationship

may simply give positive responses to all items without making distinctions between different types of questions. Thus, before a measure of conflict is used, it is important to demonstrate that it is distinct from measures of general relationship satisfaction, and if the measure is intended to assess specific components of conflict, each component should be distinct from the others.

In research using a structured laboratory setting, two questions regarding validity are commonly raised. First, do people behave differently because they are being video-recorded? On the one hand, it is likely that people act nicer toward each other in a laboratory setting than they do privately at home. On the other hand, partners often find that it is extremely difficult to alter their conflict communication, even when they are being video-recorded, and researchers are typically able to observe a wide range of communication behavior in a laboratory setting. The second validity question is whether observed communication behavior might be influenced by the topic of conflict chosen for discussion. Research with married couples has found that spouses communicate differently depending on whether the topic involves a change requested by the husband or the wife. However, research has generally shown that spouses do not alter their style of communication when they shift from discussing an extremely difficult topic to a relatively minor area of disagreement.

Another issue is whether methods of assessing conflict are equally valid for people from different populations or cultural groups. Because most people like to keep their conflicts private, the types of people willing to participate in research on conflict (and especially observational research) may not be representative of the general population. There also may be important cultural differences in how people negotiate conflict. For example, research finds that husbands in the United States show more withdrawal than husbands in Pakistan. The assessment methods discussed above will likely prove valuable in future research seeking to compare and contrast how people from different cultures and populations go about resolving their conflicts.

CONFLICT PATTERNS

Conflict patterns are the behaviors displayed in relationships around areas of dissatisfaction or disagreement. These behaviors include verbal and nonverbal actions that occur before, during, and after an argument. Conflict patterns are a natural and inevitable component of human relationships. Some psychologists also believe that conflict is important and necessary. This entry describes the most common conflict patterns, how they are conceptualized and measured, how they relate to other aspects of relationships, and cultural similarities and differences in conflict behaviors.

Types of Conflict Patterns

Generally, conflict patterns fall into three types. The first is mutual engagement in which both people are actively involved in the discussion. In this pattern, if the problem is discussed constructively by both people, the outcome may be successful resolution of the conflict. However, if there is mutual escalation or negative reciprocity (i.e., back-and-forth negativity), the outcome is typically exacerbation of the problem.

The second pattern is mutual avoidance or mutual withdrawal in which both people actively avoid (walking away from one another, changing the topic) and/or passively withdraw (tune out, halfheartedly discuss, or remain quiet) from discussion of problems, thereby preventing heated conflict but also leaving problems unresolved.

The third pattern is demand-withdraw, when one person in the relationship actively pursues changes in the other, while the other person avoids or withdraws from conflict. The person in the demanding role may complain, criticize, blame, nag, or make demands. The person in the withdrawing role may actively or passively prevent confrontation or defend. This pattern has also been called other names by authors, including pursuer-distancer, rejection-intrusion, and nag-withdraw.

Conceptualization and Measurement

Although all three conflict patterns may be present in a variety of relationships (friends, lovers, siblings, parent-child, coworkers, etc.), they are most often studied in marital or romantic relationships. Of the three, demand-withdraw has become the most salient and widely studied. Although typically referred to as demand-withdraw, this name does not imply a causal sequence of demanding causing withdrawal. Instead, the pattern of demanding and withdrawing behavior is cyclical or bidirectional, which means that each person's behavior stems from and in turn exacerbates the behavior of the other. In other words, demanding does not cause withdrawing or vice versa, but both are present simultaneously, and each one typically causes the other to increase in frequency and/or intensity. For example, a wife whose husband avoids her attempts to discuss household chores responds with more

intense forms of demand, which in turn exacerbates his withdrawal and her demands in an ongoing and mutually exacerbating cycle.

Conflict patterns are typically measured in two ways. The self-report method asks people to rate the likelihood of several different conflict patterns occurring in their relationship before, during, and after a typical conflict. Behavior observation of conflict is achieved by asking people to discuss a problem in their relationship while being audiotaped or videotaped, and then coders are trained to rate how much they hear or see conflict patterns occurring during the discussions.

Correlates and Consequences

Relationship researchers study conflict patterns to understand how they are related to the levels of satisfaction and stability experienced in relationships. For example, researchers want to understand what kinds of conflict patterns predict divorce. As expected, relationships are happier and longer lasting when more positive behaviors are displayed during conflict, whereas they are more dissatisfied and unstable when more negative behaviors are displayed around conflict. Specifically, distressed couples report and demonstrate more mutual escalation, mutual withdrawal, and demand-withdraw than nondistressed couples.

John Gottman and colleagues have identified four conflict behaviors (named the Four Horsemen) that predict unhappiness or divorce: criticism, contempt, defensiveness, and stonewalling. These researchers contend that when all four of these behaviors are present, divorce can be predicted with 94 percent accuracy. They also suggest that of the four, contempt (characterized by belittling and scornful behaviors such as eye rolling, sarcasm, mockery, insults, and hostile humor) is the most destructive to marriage relationships.

On the other hand, these researchers have also found three conflict patterns that work well for happy couples. Validators argue with mutual respect, validate the spouse's thoughts and feelings, and use compromise to resolve conflicts. Volatiles argue energetically and vigorously but also experience and express passion and warmth

during nonconflict times. Avoiders, on the other hand, downplay problems, ignore complaints, or agree to disagree, preferring to focus on the positive validators and volatiles use the mutual engagement pattern since both partners are actively involved in the argument, even though validators act more constructively, while volatiles act more negatively toward one another. Avoiders use the mutual avoidance or withdrawal pattern but remain happy because they are similar in their preference for minimizing the problem and are able to maintain enough positivity in the relationship to offset the negativity around the unresolved problem. In fact, these researchers have found that the common element to all three of these conflict styles is that they display at least 5 times as many positive behaviors as negative behaviors in the relationship. These findings suggest that even if conflict behaviors are negative, the relationship can succeed if this negativity is overshadowed by enough positivity.

Causes

Many factors influence the way a person behaves during conflict. Some of the most widely studied include individual characteristics such as (a) skill level—the amount of skill a person has in how to communicate constructively and resolve conflict; (b) gender—although many similarities exist in communication styles, differences between men and women have also been found; (c) personality traits like agreeableness (being likable and good-natured), neuroticism (being prone to anxiety and bad moods), and locus of control (beliefs about the amount of control one has in determining the outcome of conflict); (d) amount of stressors in one's life; and (e) one's goals in the discussion, such as bringing about changes, maintaining harmony, defending one's character, and so forth.

Growing attention is being paid to sociocultural and contextual influences such as ethnicity, sexual orientation, social setting (presence or absence of others), cultural ideologies about appropriate behaviors, work stresses of the particular day, relationship qualities such as amount of affection routinely expressed, and even the atmospheric temperature and humidity.

Gender Differences

One of the reasons the demand-withdraw pattern has garnered so much attention is because many early studies of the pattern found a gender difference in these behaviors. Specifically, researchers found that women were more often in the demanding role during conflict, while men were more often the withdrawers.

There are three perspectives on what causes these gender differences in demand-withdraw behaviors around conflict. The first two represent nature and nurture perspectives. The nature perspective posits that men and women are hardwired differently, and therefore, their innate biology causes them to act the way they do (with men more withdrawn and women more engaged during conflict). For example, the Escape Conditioning Model suggests that men are more likely to withdraw because they are more physiologically aroused by relationship conflict than women. Therefore, men withdraw to cope with the adverse emotional reactivity they experience, while women are able to sustain higher levels of engagement. Existing research is divided on whether men or women are more physiologically aroused by conflict, and some findings suggest no gender differences at all. Further, recent findings suggest that the demander is actually more physiologically aroused than the withdrawer.

From the nurture perspective, men and women are socialized to act in different ways in relationships. For example, women are socialized to express emotion, seek emotional intimacy, and value relational connectedness, whereas men are socialized to be autonomous and inexpressive. These differences inevitably lead women to prefer talking about feelings and problems to restore relational harmony, whereas men prefer avoiding these discussions.

Again, according to the nurture perspective, the type of marital structures and power differences espoused in a society, such as traditional or patriarchal marriage (husband-dominant) versus egalitarian (equal power shared by husband and wife), would influence the type of conflict patterns used. This situation could actually mean that wives would be socialized to be more withdrawing and husbands socialized to be more demanding, instead of the reverse. For example, some countries such as Pakistan espouse patriarchy, and others such as the United States encourage more egalitarian marriages.

Interestingly, although wives are more likely to be in the demanding role and husbands in the withdrawing role among American couples, this pattern is reversed among Pakistani couples. Among Pakistani couples, wives are more likely to withdraw than husbands, and husbands are more likely to use demands than wives. These findings suggest that demanding and withdrawing tendencies during conflict are strongly influenced by sociocultural context.

The third perspective, advanced and supported by research conducted by Andrew Christensen and others, is called the conflict structure view. According to this perspective, behavior during conflict depends not on gender, but on the position taken on the particular topic. Specifically, the person more invested in seeing change occur takes on the demanding role, while the person more invested in the status quo takes on the withdrawing role. For example, if a husband and wife are discussing household chores (because the wife wants the husband to help out more around the house), the wife is more likely to demand while the husband is more likely to avoid or withdraw. On the other hand, if the same couple is discussing finances (because the husband would like the wife to spend less), the husband is more likely to demand while the wife is more likely to withdraw or avoid. In sum, from this perspective, the kinds of behaviors displayed depend on the structure (or topic) of the conflict. Research shows that this kind of flexibility in conflict behavior depending on the topic of the conflict appears to be most likely among happier couples and among couples who have been together fewer years.

Cultural Similarities and Differences

Limited research has examined conflict patterns across cultures. There are mixed findings regarding which groups display more negative or positive behaviors during conflict. However, a consistent finding is that the level of satisfaction or distress in a relationship is associated with the amount and type of conflict patterns used. This finding means that regardless of culture, race, or other aspects of diversity, couples' happiness in their relationships depends in part on how they behave during conflict. Some research suggests

that this is even more so for Caucasian Americans than other groups, and other results suggest no differences among various groups in the strength of this association.

Cross-cultural research has demonstrated that demand-withdraw is present in countries outside North America, such as Brazil, Italy, Taiwan, and Pakistan. Similar to those of North American couples, the relationships in each of these countries that are characterized by more demand-withdraw are also more unhappy.

Research on same-sex couples shows that they share many similarities with opposite-sex couples. For example, they report similar amounts and types of conflict behaviors, these behaviors are similarly related to their level of happiness or distress, and they similarly predict relationship outcomes. Same-sex couples are also similarly characterized by one partner tending to be demanding and the other withdrawing during conflict. In same-sex couples, partners higher in femininity, desiring more closeness in the relationship, and more committed are more likely to demand during conflict, while partners lower in femininity, desiring more distance in the relationship, and less committed are more likely to withdraw from conflict.

CONFLICT PREVALENCE AND SOURCES

People often gravitate toward relationship partners who hold attitudes and values similar to their own. Yet, though partners are similar, they are not identical. By their very nature, relationships consist of two people who each bring a unique set of goals, needs, and preferences to the table. As a result, situations are likely to arise in which both partners cannot simultaneously have what they want, leading to disagreements even within happy and established relationships. For this reason, choosing a mate has been likened to choosing the particular set of problems that one is willing to contend with in the years to come. Recognizing the inevitable presence of conflict in relationships, relationship scientists have sought to determine just how prevalent conflict is within intimate relationships and to determine the factors that may exacerbate conflict between partners. The purpose of this entry is to highlight common precursors of relationship conflict.

Frequency and Topics of Relationship Conflict

To examine the frequency of conflict within relationships, researchers have generally asked couples about the kinds of interactions they have with their partners each day. This research indicates that many of the important interactions that couples report are, in fact, arguments. Interestingly, this research also suggests that particular times of day and locations may foster disputes between partners. Arguments are more likely to occur in the kitchen than any other location and are most

likely to occur on weekdays. In fact, the early evening weekday hours, when partners are transitioning from work to their roles at home, seem to be a particularly turbulent period for couples. Moreover, the frequency of arguments tends to be linked to partners' overall relationship satisfaction. Unhappy couples report twice as many unpleasant interactions as do happy couples (approximately four versus two over a 2-week period), even though unhappy couples actually spend less time together on a daily basis. Not surprisingly, then, difficulty communicating and resolving conflict is the primary reason couples seek relationship counseling.

So what do couples argue about? Although one might expect the topics of disagreement to be as varied as the people in the relationships, researchers have found remarkable commonalities across couples in the types of incidents that trigger arguments. One study examining heterosexual, gay, and lesbian couples revealed that all three types of couples report their most common topics of disagreement as falling into the areas of power (e.g., decisions regarding money and division of labor) and intimacy (e.g., affection and sex). Further research shows similar findings. In several studies, couples were presented with a list of possible sources of relationship problems (e.g., religion, children) and asked to select which topics represented sources of difficulty in their relationship. The topics most frequently identified by couples as sources of relationship conflict were money, communication, and sex. Moreover, these issues have been cited as problematic by couples in different relationship stages (i.e., premarriage, newly married, and later marriage), suggesting that the sources of relationship conflict remain fairly consistent over the course of a relationship.

Why Do Couples Argue? Incompatible Goals and Misperceived Intentions

Why are some topics particularly difficult for couples to navigate? Some theories suggest that conflict is the result of incompatible goals between partners. According to this view, conflict arises when one person pursues his or her goals in a way that interferes with the other person's goals. For instance, conflicts regarding money may begin if

one partner believes it important to save money for the future, while the other partner prefers to splurge on desired items in the present. Unless partners are able to strike a compromise between their differing goals, conflict is likely to escalate and lead to feelings of relationship dissatisfaction.

The process of negotiating differing goals, however, is complicated by the fact that partners sometimes find it difficult to express their needs and perspectives effectively. Research examining the communications of both happy and unhappy couples suggests that while most individuals have positive intentions when expressing themselves to their partner, they are frequently unsuccessful in translating those thoughts and feelings into a positive behavioral expression. In fact, positive messages seem to be more difficult than negative messages to convey effectively. Moreover, even a well-sent positive message might not be perceived as such by the receiving partner. Further studies have compared spouses' ratings of their partners' communications with the ratings made by trained independent observers. Among happy couples, spouses tended to rate their partners' statements as more positive than did independent observers. Conversely, among unhappy couples, spouses rated their partners' statements as more negative than did the outside raters. In particular, unhappy spouses often perceived neutral statements (as rated by independent observers) as negative. Thus, disagreements arise not simply because of differing goals but because the process of discussing those goals with a partner can create a situation of ineffective communications and misperceived intentions.

Is Conflict a Product of the Person or the Relationship?

Although conflict is a component of all relationships, some people clearly are less capable than others of resolving relationship disagreements. Is this because these individuals are generally deficient in their interpersonal skills (e.g., poor conflict resolution represents a trait of the individual)? Or are disagreements simply more likely in some relationships than others (e.g., poor conflict resolution represents the state of the relationship)? Evidence supports both perspectives. For instance, some research suggests that individuals' conflict

resolution skills are heavily influenced by how conflict situations were handled in their families when they were growing up, a phenomenon referred to as the intergenerational transmission of behavior. One study found that adolescents who had warm, nurturing relationships with their parents exhibit more warmth and less hostility in their intimate relationships 5 years later. Similarly, a study of dating couples revealed that women raised in families characterized by poor communication and little emotional involvement were more likely to respond to a partner's negative behavior with further negativity (e.g., angry communications) during conflict discussions. Thus, rather than diffusing a partner's negativity with positive comments, these women responded in ways that escalated conflict. Finally, studies of married couples reveal that spouses from broken or aggressive homes are more likely to display negative and aggressive behavior toward their partner. In fact, one study found that 26 percent of people who had seen their parents engage in aggression behaved aggressively in their own relationship. However, among people who had not witnessed their parents engaging in aggression, only 10 percent behaved aggressively in their own relationship. Thus, at least to some degree, conflict resolution behaviors may be the product of the individual, as people learn their relationship behaviors from their parents.

Poor conflict resolution, however, cannot be blamed entirely on individuals not knowing better forms of communication. Some studies have observed spouses engaging in problem-solving discussions with their partner and separately with a stranger. Comparing these discussions reveals that spouses tend to display more negative behavior and less positive behavior when talking with their partner than when talking with the stranger. These findings suggest that spouses were capable of engaging in effective problem solving but were not using those skills when interacting with their partner, suggesting that poor conflict behavior can be specific to particular relationships.

When are couples more likely to behave poorly toward each other? Clearly, couples vary in how many issues they have to disagree about (e.g., how to spend leisure time together, jealousy issues, intrusive in-laws, etc.), and couples facing more problems tend to behave more negatively with each other. However, research has also examined

the role that stressors originating outside of the relationship, such as work stress and financial difficulties, may play in shaping interactions between partners. This research suggests that disagreements are more likely on days when partners report experiencing more stress. Further evidence examining married couples over the early years of marriage indicates that when couples are experiencing especially high levels of stress, they are more likely to engage in psychological aggression (e.g., yelling or storming out of the room) during conflict interactions. Conversely, at times when stress is lower, these same couples are able to resolve their conflicts in a more positive and constructive manner. These findings indicate that identifying precursors of conflict requires understanding not only which couples are prone toward negative problem-solving behaviors but also when all couples, regardless of their general conflict skill level, may be more likely to engage in negative behaviors.

When Conflict Turns to Aggression

Particularly heated or frustrating conflict exchanges can sometimes escalate to the point where couples engage in mild forms of assault, a situation known as common couple violence. Generally, this term refers to acts of pushing, grabbing, or slapping the partner, as well as to throwing objects at the partner. Common couple violence is quite prevalent within intimate relationships. More than half of engaged couples report either husband-to-wife or wife-to-husband aggression (or both) in the year before marriage. Moreover, one study of newlywed couples found that almost all of them engaged in psychological aggression and approximately one fourth of them engaged in some act of physical aggression (e.g., throwing something at their partner or hitting their partner) in the first 4 years of marriage. Prevalence rates among dating couples are slightly lower, perhaps because dating couples tend to have less contact and exert less control over each other than engaged and married couples.

Is Resolving Disagreements the Key to Relationship Happiness?

Given the prevalence of relationship conflict, is the key to a successful relationship finding ways

to effectively solve relationship disagreements? Recent approaches to couples' therapy suggest that couples' goals should not be to solve their problems per se, but to improve how they discuss their differences. From this perspective, effective communication may not always lead to solutions, but it does prevent the development of negative feelings and divisiveness between partners.

Supporting this idea, numerous studies have found that the way couples talk about marital difficulties predicts not only current levels of marital satisfaction but also changes in satisfaction over time. One study observed newlywed couples discussing issues they wanted to improve in the relationship. Spouses who expressed more positive affect, such as humor or affection, when talking about these issues maintained the highest levels of satisfaction over the early years of their marriage. Moreover, displaying negative communication behaviors, such as criticizing or devaluing one's spouse, was not necessarily predictive of greater declines in satisfaction over time as long as spouses also expressed positive affect during the discussion. Thus, it is not just what couples say during arguments but also how they say it that matters for their long-term relationship satisfaction.

CONFLICT RESOLUTION

Conflict is a daily part of human existence. Although there are different types of conflict ranging from subconscious or internal struggles to clashes between nations (e.g., war), conflict can be defined as a state of disharmony between incompatible or antithetical persons, ideas, values, or interests. Conflict may involve a zero-sum mentality in which one person's goals are accomplished only at the expense of someone else. For example, someone gets a job while another person does not. This entry examines different types of conflict resolution and how it is commonly defined and measured. It discusses contemporary theories of conflict that focus on positive and negative aspects of conflict, persuasive arguing, diffuse physiological arousal, and imagined interaction Conflict Management Theory. Concurrently, this entry will review existing research about conflict resolution in interpersonal relationships.

Types of Conflict Resolution

Resolving conflict refers to a variety of strategies, which include compromise, negotiation, mediation, and arbitration. These techniques are applied to settling interpersonal, organizational, business, community, and international disputes. Robert Blake and Jane Mouton identified five strategies of managing conflict in business organizations that are frequently cited in the conflict resolution literature. These strategies are smoothing, forcing, withdrawal, compromising, and problem solving. These strategies also apply to a variety of relationships, which include friends, rivals, and close intimates.

Smoothing involves the loser of the win-lose configuration and represented the loser cooperating with the winner and being low in assertiveness. The winner of the win-lose model undertook forcing, which included the winner being low in cooperation and highly assertive with the loser. Traditional conflict avoidance (withdrawal) was seen as low in both assertiveness and cooperation. Compromise is moderate in both assertiveness and cooperation. Compromise represents high cooperation with the needs of others along with low assertiveness of one's own needs. Neither party is completely satisfied or dissatisfied. Sometimes, this compromising has been referred to as lose-lose because both parties may feel frustration at not achieving their optimal goals. The final strategy, problem solving, reflects a win-win option in which there is mutual accomplishment of goals that integrates both high assertiveness of one's own needs coupled with high cooperation in solving the needs of others.

Measurement

Conflict resolution is measured through a variety of procedures including self-report questionnaires, behavioral observation and coding of arguments and conversations, and clinical interviews. A popular scale that has been validated cross-culturally and measures conflict and violence is Murray Straus's Conflict Tactics Scale (CTS). The scale measures the frequency and intensity of the following strategies: withdrawal, reasoning, verbal threats, moderate physical coercion (e.g., slapping, scratching), and severe coercion (punching, choking). The CTS is a popular instrument that measures physically coercive strategies (e.g., hitting) as well as withdrawal, threats, and calm discussions. It has been cross-culturally tested in over 31 countries and discriminates between the sexes with men using more intense strategies such as punching and women using less severe strategies such as slapping.

The behavioral observation of conflict tactics in which verbal and nonverbal behaviors are coded is used by a variety of scholars. For example, research has examined the conflict resolution tactics among happy and unhappily married couples who end up divorcing. Sample codes for husband-wife include

complaints versus criticisms. Complaining is constructive, while criticisms are destructive. Complaints are concerned with a specific issue (e.g., failure to be on time for a specific appointment). Conversely, criticisms are more global and reflect negative judgments about the partner's personality. "You always" or "you never" statements are common as well as ridicule and sarcasm. Happy couples use more complaints, while unhappy couples more often criticize.

Nonverbal tactics that are commonly coded reflect the emotional sentiment of the partners while arguing. These are coded as positive affect, negative affect, and neutral. Research typically indicates that nonverbal codes are more powerful discriminators among happy compared to unhappy couples. Yet while arguing, happy couples are more likely to state a complaint with neutral affect that is responded to with a statement such as an agreement that validates the complaint (e.g., "I understand what you are saying. It must be rough"). Unhappy couples use a pattern of countercomplaining in which a complaint is responded to with a countercomplaint that is stated with negative affect.

Studies reveal that the frequency of arguing does not predict relational instability, breakups, or divorce. Rather, it is how the arguing is done. Arguing with contempt, expressed through nonverbal expressions such as eye rolls and smirking facial expressions (e.g., scorn), is a very powerful cue of ineffective communication. Additional ineffective conflict resolution strategies include stonewalling or withdrawal and defensiveness. In terms of stonewalling, research has indicated that so-called strategies of time-out are ineffective in controlling conflict because the individual often keeps the conflict alive in the mind by having imagined interactions in which he or she imagines arguing with the partner. It is common to relive the conflicts in the mind and ruminate about them, which may result in physiological arousal and anxiety. Additionally, individuals mentally plan or rehearse for anticipated encounters with the party. Hence, while out of sight, the person maintains the conflict in his or her mind unless he or she is engaged in other tasks.

Conflict resolution is observed in interaction laboratories in which behaviors are coded using content analysis of themes. In addition,

physiological behaviors are monitored including heart rate variability, blood pressure, and somatic activity in the form of wrist movements. Couples are videotaped discussing events of the day and grievances. A variety of variables are examined, including effects of background music (music therapy), and non-verbal behaviors used while interacting, including eye gaze, gesturing, touching, smiling, smirking, body lean, and body posture.

Negotiation is often studied in laboratory experiments in which individuals are randomly assigned to conditions. These studies have mostly looked at antecedents of the strategies adopted by negotiators and the outcomes attained, including whether agreement is reached, joint benefit to both parties, and the individual benefit to each party. For example, the person who makes the first offer tends to achieve greater benefit than the other party.

Conflict is easy to monitor in couples in laboratories. A list of topics is provided to relational partners, and they are asked to rate how pleasing or displeasing the topics are (e.g., social life, openness of communication, spiritual values, job, fidelity). Subsequently, they are asked to discuss the most displeasing topic. Another procedure uses a modification of the Inventory of Marital Conflicts. The inventory has been used in numerous studies in marital interaction. However, it can be modified to apply to other relationships. Fictional opposing scenarios are presented to partners, who are instructed to try to persuade each other to their point of view.

Aside from surveys and behavioral coding of conflict strategies, interviews are often used. Individuals are asked about recent conflicts and how they were handled. This question represents what is called a retroactive imagined interaction, as individuals replay in their minds repetitive arguments. They are queried about how they handle conflicts and if alternative strategies could have been used to facilitate more productive outcomes. Interviews are commonly used by social workers, communication skills interventionists, or therapists. For example, court-referred anger-management course instructors often used direct interviews to learn about the history of conflict while devising conflict-resolution strategies that the individual can understand.

Theories of Conflict

The study of conflict resolution requires an understanding of explanations for why conflict and violence occurs in interpersonal relationships. Following are brief explanations of popular theories of conflict resolution.

Conflict Theory

Conflict theorists take a counterintuitive approach to why conflict is an integral characteristic of the human condition. Conflict includes positive and negative qualities. Conflict is seen as natural. The key is to use conflict productively rather than intensely. Some positive qualities include increased understanding of alternative positions on issues, self-growth by discovering repressed skills in oneself (e.g., discovering that in stressful conflicts, people have latent skills that had not been used before), and mobilization of energy to the extent that conflict can energize and focus thoughts, as opposed to being in a state of complacency or mindlessness (using scripted or automatic behavioral routines).

Persuasive Arguing-Argumentative Skills Deficiency

A popular explanation for conflict is that individuals are frustrated by an inability to communicate their feelings. These people are conflict-avoiders who do not enjoy arguing and who may become defensive if they feel trapped. Conversely, conflict-engagers enjoy arguing for its intellectual merits. Numerous studies by John Gottman and Dominic Infante have demonstrated that volatile or high argumentative couples are seen as more credible, eloquent, creative, and self-confident. They are willing to initiate arguments, discuss controversial issues, and express disagreement. Conversely, avoiding or low argumentative couples dislike arguing, shy away from conflict, withdraw from arguments, and are reluctant to voice disagreement. Ideally, there is a balance between precipitating arguments needlessly and avoiding arguments altogether.

People who lack argumentative skills can become frustrated because of their inability to articulate what they are feeling. As a result, verbal aggression in the form of name-calling, insults,

put-downs, sarcasm, offensive language, racial or sexist epithets, threats, and ultimatums are likely to be used. Nonverbal contempt may be signaled through the rolling of the eyes, gritting of teeth, and constriction of eye pupils as the frustrated person exhibits facial expressions reflecting mockery or disdain.

Individuals can be both high in argumentativeness and high in verbal aggressiveness even though research has indicated that the correlations between the two are typically low to moderate. Moreover, Western cultures based on an individualistic as opposed to collectivistic orientation have demonstrated a cultural bias for argumentativeness in which competition is rewarded over cooperation. In addition, research has revealed sex differences in arguing and verbal aggression. Although there is ongoing debate in the literature, following are some stereotypes that have various degrees of empirical support. Males are more argumentative in public than females, interrupt more, and are more prone to verbal escalation such as losing their tempers. Females initiate discussions of problematic relational issues and complain of male withdrawal during discussion of serious topics. There is considerable debate as to which sex is more verbally aggressive, with some researchers arguing men and others, women.

The argumentative skills explanation of conflict espouses the view that lack of argumentation skills is a catalyst for physical and emotional violence. Indeed, the lack of effective conflict management skills is a major issue in partner abuse, including familial violence. Hence, arguing can be constructive to the extent that individuals are focused on the topic as opposed to going off on tangents. This strategy reflects "gunnysacking," in which individuals unleash a repressed set of grievances on another even if they are unrelated to the specific discussion at hand.

Research has revealed positive tactics for dealing with conflict, including using positive understanding while arguing. Examples of this strategy are being able to say that one is sorry for a misunderstanding and resolving the problem so that both partners are happy. Another strategy is rationality, which reflects restrictive rules for arguing because they restrict another person's behavior in terms of telling them what they should not do. Examples are not raising one's voice, not arguing, and not getting

angry. Conversely, positive understanding reflects prescriptive rules because they prescribe behaviors that should be performed in order to resolve conflict such as listening without prejudgments.

Conciseness and consideration are two additional conflict-resolution rules. Conciseness is a prescriptive rule and reflects behaviors such as sticking to the main point, being specific, and getting to the point quickly. Finally, consideration is a restrictive rule category and represents strategies such as not talking too much, not making someone else feel guilty, avoiding mimicry or sarcasm, and not pushing one's view as the only solution or the correct choice.

Although all of these strategies for resolving conflict are seen as characterizing happy and satisfied relationships, signaling positive understanding while arguing is most important in constructive attempts to resolve conflict. Indeed, positive understanding also signals a sense of empathy and perspective taking, as the other person's point of view are considered. Indeed, signaling positive understanding can be viewed as an art because of the variety of strategies that reflect it. On the one hand, being honest and communicating what is on one's mind reflects the strategy, but so does seeing the other's viewpoint, being able to apologize, and resolving the issue so that both parties are satisfied.

Gender and Diffuse Physiological Arousal in Couples

Gottman and his associates have studied the physiology of marital conflict, including data analyses on couples over a 14-year period. For example, physiological arousal among newlyweds while arguing is predictive of declines in marital satisfaction over time. In addition, there is data on the effects of conflict on hypertension and coronary heart disease. Yet researchers may differ in their conclusions. For example, Gottman claims that physiological arousal is more punishing for men, while Janice Kiecolt-Glaser and her colleagues argue that women suffer physiologically from the ill effects of marital or relational duress. Therefore, some researchers believe that men are more likely to withdraw from discussing sensitive topics in unhappy marriages because they are trying to prevent arousal and the release of adrenalin. Once the man is aroused, it takes him longer for

the heart rate to return to a basal level. Furthermore, in discussing serious issues in their relationships, some researchers claim that there are gender differences with unhappy men withdrawing from conflictual discussions. Conversely, in happy marriages, men are less likely to withdraw from conflict.

Other research reveals higher systolic blood pressure for unhappily married males while arguing compared to happily married males. Over 80 years ago, research about marital grievances found that husbands were concerned about their wives' criticisms and escalating emotion, while wives were concerned about their husbands' withdrawal and aggressiveness (e.g., "He is quick-tempered and argumentative"). Other research reveals males being worse at soothing themselves after a big argument, perhaps to maintain adrenalin for purposes of later counterattack. For example, after exposure to anger-inducing situations, male heart-rate and blood pressure remain high but are reduced in a retaliation condition while the opposite was true for females.

In summary, diffuse physiological arousal means that conflict is harder to resolve when males are aroused and agitated. A controversial claim is that in happy marriages, women are more likely to use an editing function in resolving conflict, as they are more likely to deescalate conflict by using validating statements, agreements, and positive emotional or nonverbal affect (happy voice tone) as they state their views. Furthermore, in using the editing function, women are trying to calm men down if they are agitated. Gottman claims that it is harder for men to soothe themselves once they are aroused and that women are better at calming themselves. These findings are still debated in the literature with varying levels of support.

Imagined Interaction Conflict Management Theory

One current direction in conflict resolution involves the use of mental imagery about arguing through imagined interactions. Imagined interaction Conflict Management Theory explains how conflict persists in interpersonal communication through mental imagery and imagined interactions. Imagined interactions are mental dialogues that people have in which they relive prior conversations while anticipating new encounters. Conflict-management theory provides a mechanism explaining why conflict

is enduring, may be constructive or destructive, and can erupt anytime in relationships. This theory consists of a series of axioms and theorems derived from empirical support that explain the daily persistence of conflict. For example, one theorem indicates how retroactive and proactive imagined interactions help keep conflict alive within the human mind. A retroactive imagined interaction occurs when a person replays a previous argument in their mind, whereas a proactive imagined interaction involves anticipating conversations before they occur in order to rehearse more constructive strategies.

Importance of Resolving Conflict

The causes of conflict are important to understand in order to devise constructive resolution strategies. There are multiple causes including biological and biochemical causes as well as personality and situational determinants. To the extent that biology and personality comingle, there is debate over the veracity of time-out as a conflict resolution strategy. According to Conflict Management Theory, many arguments are repetitive, as people ruminate over past grievances. Furthermore, during time-out sessions, individuals are likely to stay agitated as they replay the arguments in their minds, creating further distress. A continuing avenue for research involves assessing forgiveness or nonforgiveness for long-standing grievances.

CONNECTEDNESS, TENSION WITH AUTONOMY

In a symbolic sense, humans, like birds, need both a nest for stable connections and wings to soar freely toward greater autonomy. This comparison underscores how important it is for people both to become securely connected and to explore greater autonomy within marriage, parent–child, dating, friendships, workplace, and other intimate relationships. Consistent with these ideas, this entry describes autonomy and connectedness, with a special focus on whether individuals experience either tension or compatibility between these aspects of their intimate human relationships.

Autonomy is a component of individualism, or an assortment of socially valued qualities that allow a person to become more self-directed and self-governing. The development of personal autonomy consists of several aspects of relationships including (1) affirming one's personal rights, (2) exercising freedom of choice in life decisions, (3) demonstrating self-initiated behavior, (4) experiencing and controlling personal emotions separate from the emotions of others, and (5) developing one's own system of values and beliefs. Autonomous qualities are believed to be central features of relationships in Westernized societies such as the United States and Western Europe but are present in other cultures to a lesser degree. In contrast, connectedness is a component of collectivism, or an assortment of socially valued qualities that emphasize the importance of social responsibility, attachment to others, and group togetherness. Personal connectedness involves several aspects of relationships including (1) seeking frequent contact and emotional closeness with others, (2) expressing affection, (3) striving for harmony within groups, (4) emphasizing one's responsibility to other group members, and (5) complying with group expectations and promoting group interests. Aspects of connectedness are believed to be most common among members of Asian and Hispanic societies but are present in other cultures to a lesser degree. Evidence is growing that people in most, if not all, societies encourage some degree of balance between autonomy and connectedness.

Different Views of Autonomy and Connectedness in Relationships

How a person experiences autonomy and connectedness within intimate relationships is commonly described in terms of three perspectives: (1) tension or conflict, (2) compatible development, and (3) mixed patterns of tension and compatibility.

Tension Between Autonomy and Connectedness

The belief that people experience tension between autonomy and connectedness is the traditional and increasingly the most criticized of the three perspectives. A tension point of view represents autonomy

and connectedness as general aspects of relationships that are in conflict with each other. This means that increases in autonomy of any kind often lead to proportionate decreases in connectedness of any kind.

A tension viewpoint is illustrated in classical and more recent versions of psychoanalytic theory, which propose that gains in children's autonomy occur as they separate from earlier bonds they have formed with parents. During childhood and adolescence, this separation process is a normal feature of growing up that is proposed to have positive consequences for the progress of youth toward adulthood. During adolescence, for example, the young are supposed to gain autonomy by separating or becoming less connected to parents as they spend more time with peers, begin to date, experiment with sexuality, and become committed to their own values. They also learn to make more of their own lifestyle choices about such things as entertainment, music, and styles of dress.

A tension viewpoint portrays adolescents as achieving autonomy through a separation process as they spend less time with and reduce the quality of ties they have with parents. Gaining autonomy through separation provides the young with greater freedom from the physical and emotional controls of parents so they can make their own life decisions and engage in intimate relationships with people outside their families. A common feature of parent-adolescent relationships that fosters this separation process is the increased level of tension, conflict, and turmoil that is supposed to be common during this developmental period. Conflict and turmoil contributes to increased adolescent separation, which creates the conditions for greater youthful autonomy at the expense of connections with parents.

Compatibility Between Autonomy and Connectedness

Contrasting with a tension perspective is the more recent viewpoint that people experience autonomy and connectedness as compatible and as developing together. A compatibility perspective proposes that individuals do not routinely become more autonomous by sacrificing connections with others. Instead, some degree of balance or essential harmony between autonomy and connectedness is

a normal experience within intimate relationships that are healthy. Humans are viewed as products of both their individual or private experiences as well as their connections with spouses, children, work colleagues, friends, and others within relationships. A compatibility viewpoint focuses primarily on how people experience autonomy and connectedness in similar ways and less on how these aspects of relationships differ from one circumstance to another.

An example of a compatible viewpoint is provided by Attachment Theory, which can be used to explain how people develop and experience connectedness and autonomy during the entire lifespan. The emergence of attachment behavior by infants, an early form of connectedness, contributes to close ties between infants and attachment figures (e.g., parents) or people who serve as sources of security and protection. Infant-to-parent attachment involves such behaviors as crawling and eye contact to maintain close proximity, clinging responses for protection, and affectionate behaviors (e.g., cuddling, snuggling, and smiling) for emotional support. Attachment relationships also may provide the young with an internal working model or a set of beliefs about what to expect from relationships and how they will work in the future. These expectations for relationships are believed to provide a basic model for later life about how to balance connectedness and autonomy within dating, marriage, friendship, and other intimate associations.

Concerning the compatibility issue, Attachment Theory offers the idea that most people who have experienced secure attachment relationships are less likely to experience conflict between autonomy and connectedness in either their early or later relationships. Instead, autonomy is not only portrayed as being compatible with connectedness but also as springing from the close ties that a person has experienced in secure attachments with others. Autonomy begins early in development, as infants gradually expand the distance they crawl away from their parents to explore objects in the environment. During childhood, adolescence, and adulthood, the process of gaining autonomy retains this common theme of constantly expanding explorations through increasingly more complicated behaviors. Individuals use parents, friends, dating partners, and spouses as sources of security and

springboards for more elaborate excursions into the social world. For example, most teenagers do not simply reject positive relationships with parents as they gain greater freedom from parental connections. Instead, teenagers often expand the number and complexity of their peer relationships, while maintaining close ties with parents. Greater autonomy is not achieved, therefore, as a zero-sum game in which gains in self-direction necessarily mean losses in connections with parents. Most adolescents report that they value making more of their own lifestyle choices and desire to spend more time with peers but without suffering dramatic declines in the love and respect they feel for parents. The development of autonomy and connectedness are not in conflict but indeed are compatible and essential aspects of human relationships that develop together.

Mixed Patterns of Compatibility and Conflict for Autonomy and Connectedness

A third perspective is that both autonomy and connectedness may occur in mixed patterns from one culture or circumstance to another. Although recognizing that autonomy and connectedness are experienced in most if not all cultures, a mixed pattern viewpoint questions the idea that autonomy and connectedness are always experienced in the same way from one culture to another. This perspective combines elements from both the tension and compatibility perspectives but without proposing that autonomy and connectedness necessarily develop together in some general way. Instead, these aspects of interpersonal relationships may contradict, complement, or function independently of each other. In doing so, greater attention is focused on the differences rather than the similarities about how autonomy and connectedness are experienced.

A mixed pattern occurs in societies that have a dominant way the majority experiences autonomy and connectedness as well as different patterns of experience within ethnic-minority communities. A specific example is the dominant experience of the White, middle-class population of the United States, which often balances these relationship qualities by assigning priority to autonomy over connectedness within family and interpersonal relationships. In contrast, the Chinese-American

ethnic community within the United States often places greater value on connectedness by assigning priority to group interests, supporting family cohesiveness, and seeking harmony with others over autonomy. Given their minority status, however, Chinese Americans often benefit from adapting to both cultures and by shifting back and forth in mixed patterns between the dominant and ethnic expressions of autonomy and connectedness as circumstances require. Consequently, Chinese Americans may practice a mixed pattern by emphasizing strong bonds of connectedness within their family lives by deferring to parental authority, avoiding conflict, and maintaining harmony among family members. However, when Chinese Americans venture into the individualistic world of the U.S. workplace, they often recognize the benefits of becoming more autonomous. Specifically, they pursue their individual self-interest by striving for personal success and competing energetically with colleagues for career promotions.

A mixed-pattern perspective also proposes that some cultures emphasize different kinds of connectedness and autonomy that may be in conflict, compatible, or some combination of the two. For example, when cultures vary in the type of connectedness they emphasize, that is, either trust or assurance, mixed results often occur in the relationship between autonomy and connectedness. Although both forms of connectedness are probably present to some degree in most cultures, other circumstances often lead to either trust or assurance being emphasized more strongly than the other.

A key factor that determines whether either trust or assurance is favored depends on how much value also is placed on autonomy. Trust is the kind of connectedness that most people prefer to express in Westernized cultures where people also place high priority on becoming autonomous. Often expressed as encouragement and affection, trust supports the development of autonomy by seeking to build a person's confidence, tolerating relationship changes, and supporting the formation of new relationships. In contrast, assurance is a form of connectedness that is more common in collectivistic societies and involves communicating about the need for cooperation, togetherness, harmony, and loyalty within groups. Assurance conflicts with autonomy by emphasizing the importance

of conforming to group interests, stability in relationships, resistance to changes in relationships, and interpersonal harmony. When assurance is emphasized, autonomy and connectedness are likely to be experienced as conflicting, but when trust is favored, people often become autonomous without reducing their connections with others. Thus, exactly how autonomy and connectedness are experienced in a particular culture may depend on the specific types of these relationship qualities that are emphasized.

Debates about the meaning and the degree of compatibility or conflict between autonomy and connectedness are likely to continue in the future. Putting together the autonomy-connectedness puzzle may rely on pieces from the tension, compatibility, and mixed-patterns perspectives. A working conclusion is that most relationships can be understood, in part, as a nest that provides secure connections and wings that make greater autonomy possible.

CONSCIENTIOUSNESS, EFFECTS ON RELATIONSHIPS

Conscientiousness, one of the Big Five dimensions, is thought to involve orderliness, dutifulness, achievement striving, self-control, and purposefulness. As such, high-conscientious persons are seen as dependable, self-disciplined, organized, and determined, whereas low-conscientious persons are undependable and easily distracted from tasks. Mary Rothbart further suggests that conscientiousness is linked with early appearing self-control processes that emerge as the frontal cortex begins to mature. In general, due to their poorer self-control, low-conscientious individuals seem to have difficulty maintaining standards and persisting in tasks in the face of obstacles. This entry describes the benefits as well as the limits of conscientiousness for childhood and adult relationships.

Is Conscientiousness Important for Relationships?

Researchers have focused most of their efforts on examining how conscientiousness relates to performance criteria. For example, conscientiousness has been related to improved task functioning across a wide range of contexts, including school and work, and has even been related to fewer driving accidents. However, recent research is beginning to understand the importance of being conscientious for maintaining high-quality relationships.

Conscientiousness in Childhood Relationships

Children and adolescents who are low on conscientiousness exhibit behavioral problems that interfere with relationships. For example, conscientiousness has been related to externalizing behaviors (e.g., impulsivity), which in turn has been associated with more friends, higher friendship quality, greater peer acceptance, and lower peer victimization. On the other hand, conscientiousness is thought to buffer against the negative effects of internalizing problems on interpersonal relationships. That is, conscientious children seem

better able to control their anxiety in interpersonal situations, a skill which leads to better relationship outcomes.

During late adolescence, conscientiousness has been associated with how frequently college-age students contact family members during their first year of school. Although the amount of contact with family members decreased for all students, the smallest decrease in contact was seen for conscientious students. Conscientious persons seemed better able to maintain relationships through more frequent communication even when separated from family members than nonconscientious persons.

Conscientiousness in Adult Relationships

Conscientiousness continues to have an influence on relationships in adulthood. Among adults, conscientiousness has been linked to higher mate desirability, higher relationship quality, and greater marriage stability. Conscientiousness also appears to play a role in how persons cope with stressors. When faced with an interpersonal stressor, persons high on conscientiousness are more likely to rely on coping strategies that help preserve the relationship during stressful periods than are persons low on conscientiousness. High-conscientious individuals are more likely than low-conscientious individuals to compromise, problem solve, seek support, and respond empathically. Due to their use of these relationship-preserving tactics, it is not surprising that individuals high on conscientiousness report fewer marital stressors than individuals low on conscientiousness. Conversely, adults who are low on conscientiousness disclose personal information more inappropriately, are less responsive to their partners in romantic relationships, have poorer interpersonal interactions, are more likely to cheat on their partners, and are more likely to divorce.

Conscientiousness is also linked with parenting. For example, conscientious mothers are more responsive to their child's needs and less likely to use power assertive tactics (e.g., spanking, threats) with their child than low-conscientious mothers. Higher levels of parental conscientiousness seem to create a supportive environment in which the child can learn about, explore, and test his or her world. However, there do seem to be limits; extremely

high levels of parental conscientiousness can place unreasonable demands on children leading to more adjustment problems. Interestingly, in collectivistic cultures (but not individualistic cultures), conscientious mothers viewed themselves as being more competent as parents than low-conscientious mothers.

Levels of conscientiousness are also influential when conflict situations escalate to anger. It has long been known that when persons become angry, they are more likely to be aggressive. However, recent laboratory research has found that this anger-aggression link is attenuated for persons high on conscientiousness. That is, there was only a relationship between anger and aggression when persons were low on conscientiousness (and most likely lower on self-control). Conscientiousness thus appears to be important in behavioral inhibition of emotions that can potentially damage relationships. In other words, given that persons who are lower on conscientiousness are more impulsive, they are more likely to lash out when frustrated by others rather than control their emotional reactions. This lack of impulse control can lead to poorer interpersonal interactions.

Conscientiousness is also important in informal organizations. For example, conscientiousness is positively correlated with peer-reported social influence and social reputation such that high-conscientious persons have greater social influence than low-conscientiousness persons. It is possible that conscientious persons are better able to present themselves as role models and regulate how others perceive them in leadership roles. In addition, conscientious individuals are often perceived to be better group members. For example, they are more likely to commit to continuing with a group, are less likely to be late or absent from gatherings, and can be counted on to meet group obligations.

Is There a Dark Side to Being Conscientious?

Given that conscientiousness is composed of many facets, the relation between conscientiousness and interpersonal relationships may take many paths. Some aspects of conscientiousness (e.g., achievement striving, order, dutifulness) may not always lead to positive interpersonal outcomes. For example, among college roommates,

persons are more likely to identify the source of conflict as a high-conscientious roommate rather than a low-conscientious roommate. In addition, similarity on conscientiousness between partners has been linked with poorer relationship satisfaction in early and middle adulthood (but not in later adulthood). These increased negative outcomes may trace back to the task-directed nature of conscientious persons. Both college and midlife are times in which persons are focused more on reaching individual goals and completing tasks (e.g., raising families, achieving high grades, and earning promotions). High-conscientious persons are more likely than low-conscientious persons to have a plan of how to best achieve their goals and complete tasks. When these plans clash, increased conflict and lower relationship satisfaction can result.

Given that conscientiousness also involves order and dutifulness, it is no surprise that conscientiousness has also been linked to right-wing authoritarianism (an adherence to conventional norms and values and an uncritical subjection to authority). Indeed, higher levels of conscientiousness have been linked to less tolerant attitudes toward illegal immigration. Although conscientiousness does not appear to have a direct association with prejudice and racism, its influence is indirect via right-wing authoritarianism.

Finally, one could speculate that because high-conscientious people are more planful and ordered, it might influence their willingness to let go and have fun. Thus, they may be perceived as less entertaining and enjoyable to be around in certain social situations. Indeed, there is some evidence that extremely high levels of conscientiousness are associated with obsessive-compulsive disorder. Further research needs to empirically examine whether different facets of conscientiousness (e.g., achievement striving, competence, order, self-control) predict positive and negative relationship outcomes.

CONTEXTUAL INFLUENCES ON RELATIONSHIPS

Studying personal relationships requires that researchers focus attention on agency. Relationships do not just happen. They are built through people's actions or, more accurately, through their interactions over time. They are, in other words, active constructions consequent in part at least on the emergent thoughts, reflections, choices, and decisions people make across time about the involvement they want to have with others. Yet at the same time, relationships are not just about agency; they involve more than simply the individual choices and decisions that those involved make. Or to put this a little differently, the choices and decisions people appear freely to make about the content and patterning of their relationships are not as free as a focus on agency alone would suggest. Rather these choices and decisions are structured by aspects of their lives over which they have little if any direct control. This entry is concerned with exploring those factors external to personal relationships that nonetheless influence their content and form. After discussing why context is important in understanding personal relationships, the entry outlines

different levels of context that impact relationships, briefly using the example of courtship to illustrate the arguments.

One element of how personal relationships are structured stems from what can be broadly termed psychological dispositions and dynamics—personality traits, attachment characteristics, and the like—which influence how individuals behave in their different relationships and in turn frame subsequent interactional responses within these relationships. But equally, the contexts in which different relationships are developed and sustained are also important in structuring these relationships. Even though at times they may be presented as entirely personal, in reality, personal relationships do not exist in a decontextualized void. Whether talking about relationships between lovers, friends, workmates, family, neighbors, spouses, or whatever, the way people “do” their relationships will be patterned by a wide range of factors external to the individuals and relationships in question. Such contextual influences are not determinate of relationships; there is always the interplay of agency and structure. Nonetheless, the contexts in which relationships are embedded provide the framework within which people actively construct their relationships.

The notion of context is inherently complex. Although the broad idea of context patterning personal relationships is largely uncontentious, it is far more difficult to be precise about the ways that different elements of context impact relational outcomes. The difficulty is that by its nature, context refers to a wide range of features external to relationships. It incorporates any and all aspects of the circumstances pertaining to a personal relationship and the individuals party to it that are not integral elements within that relationship. Potentially, context incorporates everything from the settings in which interactions occur to the sub-cultural mores of the participants to the sociohistorical structures of the period. As a consequence, the boundaries of context, and the boundaries between different aspects of context, are inherently fuzzy. Specifying those features that should be included in analyzing why particular relationships are as they are is consequently somewhat arbitrary in that it depends in large measure on the focus the researcher chooses to take.

Levels of Contextual Influences: A Schema

In discussing friendships, Rebecca Adams and Graham Allan produced a schema that attempts to clarify the different elements of context that can influence personal relationships. They highlight four conceptually distinct levels of context. They term the first of these the personal environment level. By this, they mean all those immediate features of a person’s life that structure the possibilities he or she has for developing and sustaining different relationships in particular ways. Among other things, this includes, for example, their work commitments, their domestic and family obligations, their mobility, their economic well-being, their housing circumstances, and their access to different leisure pursuits. All such features of an individual’s social and economic location play a part in shaping their patterns of social participation and, consequently, the specifics of the different personal relationships in which they are involved at any time.

The second level they identify is the network level. This level refers to the overall set of relationships that an individual sustains. Clearly, the characteristics of different people’s networks vary. Some are more extensive than others; some are more varied in the types of relationship they include; some have a greater network density than others (i.e., a higher proportion of network members who have relationships to one another). These characteristics will be partially consequent on the factors operating at the personal environment level. But network configuration can also have an independent effect on people’s relationships. That is, network characteristics themselves form part of the context in which individual relationships are—or are not—sustained. Equally, they have an impact on the opportunities people have to develop new relationships. As an illustration, people who have relatively small and configurationally dense personal networks are likely, as a direct consequence, to have fewer opportunities for developing new relationships than those whose existing networks are more loose knit and more extensive.

The third and fourth levels of context that Adams and Allan identify are the community level and the societal level. The community level focuses on how people’s lives, including their personal relationships, are influenced by the socioeconomic

and cultural practices that arise among different groups at different times. The most obvious examples here relate to the patterning of personal relationships emergent in economically deprived localities and in ethnic communities. Research has frequently shown how cultural norms and/or economic necessity influences the organization of the different family and nonfamily personal relationships sustained by people in these settings. Although not always so apparent, among any social grouping, shared cultural norms develop that shape people's understanding of how personal relationships should be framed and consequently influence their relationship behavior.

Similarly, at the level most removed from the individual, the societal level, larger scale socio-historical and macroeconomic factors shape the assumptions people make about how personal relationships should be routinely ordered. A classic example here concerns the impact that industrialization had upon people's familial and community involvement. Despite all the detailed debate there has been about the processes involved, few would deny that family and community solidarities were fundamentally altered as an agrarian economy gave way to an industrialized one. A quite different example concerns the recent rise in cohabitation and the concurrent deinstitutionalization of marriage. As a result of changed understandings of sexuality and individual rights, what was once "living in sin" has over a period of some 30 years become an appropriate and acceptable mode for developing romantic, sexual, and domestic commitment. Such changes in the patterning of personal relationships cannot be explained simply by individual volition. Their roots lie more broadly in the shifting sociohistorical conditions that frame normative and legal conventions governing the legitimacy of different behaviors.

It is evident that the divisions between the different levels of context identified by Adams and Allan are somewhat arbitrary. Indeed, given the nature of context, specifying precisely where one level ends and another starts is often problematic. Similarly, there is nothing special about this schema *per se*. Other ways of exploring the different components of context could be devised. This though does not undermine the main issue being raised here: Personal relationships are not just personal. Although individual agency is important in their

organization, it alone cannot account for the content and form that different personal relationships take. As argued above, the interplay of diverse contextual factors implicitly frames the ways that individuals (choose to) construct their various personal relationships.

As a brief example to illustrate the influence of context, consider here courtship, that is, forms of relatively committed premarital romantic and/or sexual relationships. Clearly courtship has taken quite different forms in different societies at different times. In part, how courtship is patterned depends on the controls over sexuality exercised within a given society and the ways in which young males and females are generally allowed to associate with one another. In cultural settings where marriages are arranged, for example in much of southern Asia, the potential spouses tend to have rather little to do with one another before the wedding, with relatively few meetings occurring. In other cultures, the courtship period may be more prolonged and involve greater individual selectivity, based upon attraction and emotional commitment (whether or not this is termed love), but with the couple still routinely being chaperoned. This, for example, was a common pattern in many areas of southern Europe in the first half of the 20th century. In contemporary Western society, in contrast, there is greater emphasis on individuality and greater acceptance of the couple's right to develop their relationship with a high degree of privacy.

From these examples, it can be recognized that community and societal levels of context shape the ways in which couples organize and manage their courtship. The freedoms granted to individuals differ significantly. Even if these examples just focus on contemporary Western courtship, they can illustrate the different ways in which context influences relationship development. Consider just two aspects of contemporary courtship: its timing and its sexual content. Taking the latter issue first, one of the more remarkable features of the last 30 years has been the changes occurring in sexual mores. While in the mid-20th century, some degree of sexual interaction was tolerated between fiancées, such activity was generally rather furtive. By the turn of the 21st, not only was virginity at marriage no longer prized by most, but more interestingly premarital cohabitation had become the

norm. To put this differently, explicit sexual involvement within committed partnerships was no longer stigmatized either by those others in the couple's social networks or by the social institutions with whom they had dealings.

This example provides a very concrete example of how the contexts in which relationships develop influence their patterning. But on the issue of timing, increases in the average age of first marriage also illustrate how changing contextual factors shape the apparently personal decisions people make. Of consequence here are changes in young adulthood and, in particular, the new opportunities available to women. Increased participation in higher education, greater control over fertility, and access to a wider range of employment opportunities have significantly altered young women's life-course options, creating greater financial independence and offering choices that were not so readily available to earlier generations. In turn, normative pressures from family and friends reflect these changes. Rather than being a period for settling down, young adulthood has come to be seen more as a period for exploring options. In these ways, personal environment and network levels of context re-enforce shifts at the community and societal levels. Early marriage now tends to be discouraged, with the early and middle 20s being seen as more a period for exploring possibilities, building careers, and gaining greater relational experience; in a sense, a time for becoming an adult rather than being an adult. In this context, marriage has tended to be postponed until a later age.

Concluding Remarks

In summary, although personal relationships are indeed personal and individual, they are nonetheless patterned by the contexts in which they are developed and sustained. The forms they take, the ways people behave in them, and the feelings people have about them are all influenced by the broader settings in which they are enmeshed. At times, people are quite conscious of how particular features of a relationship's context influence their involvement in it. More generally though, contextual factors operate as background features, without people really being aware of their impact. People simply "do" their relationships in

an unquestioning fashion, building on taken-for-granted assumptions and conventions. As social scientists though, researchers need to be aware that different contextual factors implicitly, yet inevitably, pattern the organization of personal relationships. In particular, ignoring the place of context in personal relationship research can lead to poor science by encouraging inappropriate generalizations.

CONVOY MODEL OF SOCIAL RELATIONS

The Convoy Model of Social Relations is an interdisciplinary concept that describes the formation of social relations and how they affect health and well-being. The term *convoy* is borrowed from anthropologist David Plath who used the term to describe the birth cohorts of children he observed in Japan. From birth through adulthood, these children were consociates or members of a convoy that provided the indispensable feedback that

leads to maturity. Robert Kahn and Toni Antonucci used the term to describe the group of close social partners who surround an individual providing protection, care, and socialization, which in turn influence their health and well-being. The Convoy Model is an integration of developmental, social, and organizational psychology concepts. It strongly emphasizes the life-span cumulative aspects of development and the life course situational context; that is, the roles and organizations. This entry describes the different types of social relations, their antecedents and consequent characteristics, as well as supporting empirical evidence.

The Convoy Model identifies multiple dimensions of social relations: social networks, social support, and support satisfaction or adequacy. Social networks refer to the objective descriptive characteristics of social relations such as age, gender, relationship, and years known. Social support refers to the actual exchange—that is, provision and receipt—of support. Social support has been defined in many ways but generally includes aid, affect, and affirmation. Aid is most commonly understood as tangible support but can also include less tangible support such as advice and information. Examples include lending money, providing sick care, helpful suggestions, and problem solving. Affect refers to emotional support such as love and affection. Affirmation is the communication to the supported person, an affirmation of his or her perspectives, values, or norms. And finally, support satisfaction or adequacy refers to the individual's evaluation of the support he or she receives. This construct is meant to recognize the importance of the psychological evaluation of objective social network structure or support exchanged. For example, one individual might evaluate the receipt of \$100 as sufficient support and another consider \$1,000 insufficient. Similarly, one expression of love per week might be considered adequate to some, whereas daily expressions of love might be considered woefully inadequate to others.

The original Convoy Model identified two kinds of antecedent characteristics, personal and situational, that fundamentally influence social relations. Personal characteristics refer to individual factors such as age, gender, race/ethnicity, religion, and education. These characteristics affect the type

of social relations individuals require, expect, and value. Situational characteristics refer to the norms and expectations of the roles and environment in which the person is situated—the overall context within which the individual lives. Situational characteristics recognize the group or cultural context within which the individual experiences his or her personal characteristics. Examples might include the difference between living in Montana as compared to Manhattan, working in a factory versus at a university, or being on the “Mommy” track rather than the corporate track. The combination of personal and situational factors is important for social relations and health. Thus, for example, being Catholic in Boston, Asian in California, or a high school graduate in a factory town are all very different from being a Catholic in Kansas, Asian in Idaho, or a high school graduate in a high-tech locale such as in the Silicon Valley. Personal and situational characteristics influence the type of social relations that one is most likely to experience. These characteristics are ultimately considered antecedent factors that affect health and well-being, defined broadly to include psychological, physical, and mental health.

When considering the ways in which social relationships influence health and well-being, the social support literature addresses issues of direct and indirect or buffering effects. Thus, the direct effect posits that social relations might affect how one feels irrespective of stress. On the other hand, social relationships may influence how one copes with stress—the indirect or buffering effect. The Convoy Model addresses both direct and indirect effects. That is, social relations can influence general health and well-being directly at any given time and cumulatively over time. But also important is the fact that social relations can influence how an individual copes with a particular stress. To be clear, the model does not suggest that people with positive relations will never encounter stress or never have health problems but that they probably will encounter less stress and be less negatively affected by the stress they do experience.

Empirical Evidence for the Convoy Model

Recent empirical evidence has supported many aspects of the model. The association between

social relations with close significant others and health has been consistently noted and highlights the importance of core network relations to mental health. Other findings support many aspects of the original model and indicate that personal (e.g., age, gender, race, and socioeconomic status) and situational (roles, expectations) characteristics as well as stress (e.g., daily hassles, life events) influence multiple aspects of social relations (e.g., social network, social support, support quality) and health (e.g., self-rated health, diagnosed illnesses, depressive symptoms, self-esteem, life satisfaction). For instance, there are clear gender differences in social networks, especially negative aspects of social relations. Men were less happy if they wished they had more people to rely on or if their network members were too demanding, whereas women were less happy if they reported that their network members “got on their nerves.” As people age, they report less negative relationships with their children and friends, but negative relationships with spouses remains about the same. At the same time, people who are married are much more satisfied with life and tend to be healthier than people who are divorced, separated, or never married. The quality of a mother’s social relations with others affects her relations with her child, both of which influence mother and child’s well-being as indicated, for example, with depressive symptoms. Other findings indicate that support exchanges are related to quality of support, which is negatively related to stress and positively related to mental health. Fortunately, however, poor quality spousal relationships and health may be offset by high-quality friend and family relations. Self-efficacy, which can be encouraged by strong, positive social relations, can offset the negative effects of stress.

Overall, the Convoy Model is designed to highlight the importance of a long-term, longitudinal and cumulative effect of social relations, the importance of quality of relations over type or structure of relations, and the influence of social relations on health and well-being. Future work should examine these associations longitudinally in order to understand how social relations change over time and influence health and well-being.

COOPERATION AND COMPETITION

Cooperation and competition are basic properties of human social life. Whenever an individual interacts with relatives, friends, intimate partners, or business associates, their relationship will normally contain a mixture of cooperative and competitive elements (i.e., mixed-motive interactions). On the one hand, people take pleasure and pride in collaborating with others to achieve mutual goals such as raising children, creating a successful business, or winning a sports match. On the other hand, people often compete with each other to get credits for joint achievements. Cooperation can be broadly defined as a motivation to further joint interests (e.g., doing well together), whereas competition concerns a motivation to maximize personal interests relative to that of others (e.g., doing better than others). Cooperation and competition can be thought of as two contrasting motivational or behavioral strategies employed in situations in which people’s outcomes are mutually dependent. They also sometimes refer to the relationship itself. For instance, a cooperative relationship is characterized by a positive correspondence between people’s outcomes (win-win relationship), whereas

a competitive relationship is characterized by negative correspondence in outcomes (win-lose relationship). This entry investigates the origins of human cooperation and competition and some factors that promote cooperation in social relationships, based on the latest research findings in psychology and adjacent disciplines.

Issues of cooperation and competition have been of interest to behavioral scientists across many disciplines, such as in psychology, economics, biology, political science, and sociology. Researchers often use experimental game methodology to test their hypotheses. Arguably the best-known game is the Prisoner's Dilemma (PDG), a classic example of a social dilemma that pits individual against collective interests. The PDG was developed by scientists in the 1950s. The cover story for the game involved two suspects accused of committing a crime together who are independently offered the choice to testify against each other or to keep silent. The payoffs are such that each one is better off testifying against the other (the competitive or noncooperative choice), but if they both pursue this strategy, they are both worse off than by remaining silent (the cooperative choice). Thus, their best individual strategy results in a deficient collective outcome.

Theories

Historically, the dominant theory to explain cooperation and competition is (economic) game theory, which provides the logic behind experimental games and assumes that individuals are rational actors who are motivated to maximize their self-interest. Game theory predicts that players will compete in a PDG (or an equivalent game) because this, on average, gives them the best payoffs. Although this is a useful starting premise, there are many conditions under which people may deviate from narrow self-interest. As such, complementary frameworks are needed to understand broader interpersonal motives and mechanisms.

Evolutionary and social psychological approaches provide useful, complementary insights into why people cooperate versus compete. The selfish gene perspective suggests that people are motivated to cooperate if it furthers the survival of their genes. For example, Kin Selection Theory assumes that

people are more inclined to share with close kin because of overlapping genetic interests. There is considerable evidence in support of this evolutionary theory; for instance, people are more willing to share food or money with siblings (50 percent genetic relatedness) than with cousins (12.5 percent). Reciprocal Altruism Theory provides an alternative explanation for the evolution of cooperation. When people interact repeatedly with the same person, cooperation can develop because players can reward each other for cooperation and punish each other for competition (the tit for tat strategy). What about cooperation in larger groups? There are various promising evolutionary models of large-scale cooperation being developed at the moment, such as Indirect Reciprocity Theory—the idea that people cooperate so as to earn a positive reputation—and Multilevel Selection Theory—the idea that groups of cooperators have an evolutionary advantage. Yet these models wait further testing.

Psychological theories of cooperation also question the game theory assumption that individuals are inclined to compete in mixed-motive social interactions. The most prominent is Interdependence Theory, which suggests that different people interpret a particular situation differently under the influence of particular social motives, social norms, or aspects of the decision situation. Playing a prisoner's dilemma with an identical twin, for instance, changes the PDG into a game in which cooperation is considered the most attractive strategy. Also, players with cooperative dispositions attach greater weight to a cooperative outcome, thus transforming the game into one in which cooperation is rational. What are the factors that might lead to such transformations that promote cooperation? Generally, there are motivational, strategic, and structural factors.

Motivational Factors

There is overwhelming evidence for stable individual differences in how much people value certain ways of distributing outcomes between themselves and others. The literature distinguishes among three primary social orientations: (1) cooperation—maximizing joint outcomes (doing well together), (2) individualism—maximizing

own outcomes regardless of what others get (doing best for oneself), and (3) competition—maximizing own outcomes relative to others (doing better than the other). Findings reveal that most people have a cooperative orientation, which has implications for the way they behave in social settings. For instance, they are more willing to sacrifice in an intimate relationship, do volunteer work, donate money to a charity, and save the environment. They also weigh the moral implications of their decisions more heavily and perceive cooperation as the more intelligent choice. One interesting puzzle is where these individual differences come from. There are some indications that cooperators are more likely to grow up in larger families (with sibling sisters, in particular), and they are more prevalent in East Asian than in Western cultures and among women than men, and apparently, they are less prevalent among economics than psychology students. Like any other personality variable, these orientations are presumably the product of a complex interaction between genetic and cultural factors. Examples of other personality traits that have been found to increase cooperation are trust, collectivism, egalitarian values, and a secure attachment style.

A second motivational force in cooperation is people's social identifications. For example, when people highly identify with a particular social group (such as a sports team or social movement), they are more likely to contribute to their group and trust that other ingroup members will do so as well. Social identifications have an even more powerful effect in case of intergroup competition. When social dilemmas involve two groups of players, there is much less cooperation between them than when two individuals play. However, intergroup competition also drives intragroup cooperation, especially among men, and competition within groups is much less severe in the presence of an outgroup. Yet intergroup competition can be a double-edged sword. Encouraging competition between groups might serve the temporary needs of ingroup members, but the social costs of intergroup competition (e.g., prejudice, aggression, violence) can be severe for all involved parties.

There is also evidence that social norms can play an important role in eliciting cooperation in society. Norm violation can result in social disapproval or even ostracism, which are powerful

incentives to cooperate. Social norms also facilitate cooperation through protecting the weak in society from being exploited (such as norms about charity and rules about taxes and social security), and these norms create a sense of justice and fairness in society. It is noteworthy that people are concerned not only about fairness in the outcomes they receive (distributive justice) but also about the fairness in the procedures producing these outcomes (procedural justice). For instance, cooperation with authorities is much higher when people feel they have been listened to and treated with dignity and respect.

A final factor is communication. Cooperation generally increases when players are allowed to communicate. There are several reasons for this. Communication fosters a shared identity between individuals so that they are more concerned about each other's fate. It also offers an opportunity for people to persuade each other to do what is morally right. Finally, communication gives people a chance to make promises and explicit commitments about what they will do.

Strategic Factors

As previously mentioned, communication can have a strategic benefit, as it allows people to make commitments. Furthermore, particularly in repeated interactions between the same players, cooperation can stabilize on the back of a strategy called tit for tat. This strategy commences with a cooperative choice and subsequently imitates the other person's previous choice. Thus, if one partner competes, the other copies the move until the partner starts to cooperate. Tit for tat is one of the most effective means for eliciting stable patterns of mutual cooperation in all kinds of social interactions, for instance, between romantic partners, friends, business partners, and even between nations. It works well because it is nice, but firm. Yet it can be quite an unforgiving strategy, and a more forgiving strategy that does not involve immediate retaliation sometimes produces better results—for instance, in real life, people sometimes accidentally make a noncooperative decision.

Another strategic variable concerns a person's reputation. In environments in which people can freely choose social interaction partners, it may

pay for someone to develop a positive reputation through consistent levels of cooperation. Research suggests that in such environments cooperators may be better off in the long run because they are selectively favored for social exchanges from which competitors are excluded. There is even some evidence that cooperators are selectively preferred as partners for intimate relationships. Perhaps the most common manifestations of reputational cooperation are public charitable displays such as philanthropic giving or bystander helping, which usually attract large audiences.

Structural Factors

Cooperation is enhanced when there is greater correspondence in outcomes between interaction partners. Thus, interventions by which cooperation becomes structurally more attractive (reward) and competition less attractive (punishment) are instrumental in inducing cooperation. A successful example from the real world is the so-called Jigsaw class room in which students of mixed ethnicity work together in small groups on a variety of tasks in which their individual contribution is recognized rather than compete. Such cooperative activities improve educational levels and reduce intergroup prejudices. Rewards may not always be effective because they sometimes undermine people's intrinsic motivation to cooperate. Some people get a warm glow from cooperating and the provision of selective incentives might crowd out their prosocial motivations. Similarly, punishment strategies might erode people's trust in each other and backfire.

Another structural feature involves people's dependence on a relationship. In ongoing social relationships, cooperation is enhanced to the extent that people experience greater commitment to the relationship, that is, when they feel more strongly attached to the relationship and at the same time, perceive a lack of viable alternatives. Commitment is important for social cooperation in romantic relationships, friendship groups, and even in large formal organizations. For instance, people are more willing to engage in organizational citizenship activities such as organizing an office party when they feel committed to the organization that employs them.

A final structural feature is group size. Cooperation is generally higher in smaller groups. In larger groups, people may feel less personal responsibility for the collective interest and perhaps rightly believe that their cooperative contributions makes little overall impact (personal efficacy). Even so, cooperation in large groups is possible, particularly through enhancing feelings of group identity, effective communication, and strengthening social norms. Alternatively, punishment strategies might be quite effective in fostering cooperation in larger groups.

Conclusion

Cooperation and competition are vital themes in human affairs. As emerging research themes, scientists are developing novel games to study cooperation and competition, for instance, using games in which (a) participants can enter or leave, (b) be included or excluded, and (c) play multiple games either sequentially or simultaneously. There is also blooming neuroscience literature studying brain correlates associated with cooperation and competition, reward and punishment, and violation of social norms. Finally, there is an enhanced interest in applications to areas such as close relationships, organizational welfare, education, public health, national security, and international relations.

COPING, DEVELOPMENTAL INFLUENCES

Whether it is the stress of separating from a loved one, the experience of failure, or witnessing a life-threatening event, coping is necessary from the first to the last days of life. Coping describes the transactional processes through which people deal with actual problems in their everyday lives and includes such strategies as problem solving, social support seeking, distraction, and escape. Although coping has been considered an individual affair, influenced largely by personal resources (such as efficacy or optimism), it is clear that coping is profoundly social in nature. Social environments (such as families) can create stress. They shape the specific demands to which people will be exposed or from which they will be sheltered. Social relationships are the contexts through which stressors are filtered and from which coping resources may be drawn. Moreover, social partners may be directly involved in individuals' coping interactions, and they form the back-up systems that will protect people (or leave them vulnerable) when their own coping capacities prove inadequate.

Not only do social contexts and relationships shape how people cope at every age, but they also

influence how coping develops. Recent theoretical and empirical progress in the field has facilitated the study of the reciprocal connections between personal relationships and coping. This entry provides a brief overview of emerging conceptualizations of coping as a backdrop for explaining the multiple levels at which social contexts and interpersonal relationships shape how coping develops. The entry focuses on infancy, childhood, adolescence, and early adulthood.

Conceptualizations of Coping

In recent years, theorists have converged on definitions of coping as regulation under stress, arguing that coping encompasses how people of all ages mobilize, guide, manage, coordinate, energize, modulate, and direct their behavior, emotion, and orientation (or how they fail to do so) during stressful encounters. Coping is also an organizational construct, involving the coordinated regulation of all these elements. When dealing with stressful events, people attempt not only to shape emotional experience and expression, but also to manage their physiological reactions, motor behavior, attention, and cognition; they may also attempt to influence reactions from the social and physical environments. As a result, coping has been considered action regulation, with action referring to organized patterns of behavior, emotion, attention, and motivation.

A diverse range of regulatory strategies can be identified, as reflected in the long lists of coping strategies used in research on stress and coping. In one review, over 400 coping categories were identified, with surprisingly little overlap in the taxonomies that have been suggested to categorize them. To organize these many ways of coping, theorists have proposed a set of hierarchical families of coping, with each having particular adaptive functions and each encompassing multiple lower-order ways of coping. An analyses of the literature suggests 12 primary families, including those typically considered to be adaptive responses to stress, such as problem solving, information seeking, negotiation, accommodation, support seeking, and self-reliance, as well as those typically associated with distress or maladaptive responses, such as helplessness, escape, opposition, submission, delegation, and social isolation.

Developmental Level and Coping

Developmental level is one of the most interesting factors that shape the exercise of coping. In fact, developmental capacities decisively constrain the ways in which particular adaptive functions can be expressed. Because age and experience influence how stress is appraised and how regulatory strategies are enacted, researchers have tended to focus on narrow age ranges when studying stress and coping. Hence, there are studies of how infants, toddlers, preschoolers, children, adolescents, or adults react to and cope with a variety of stressors, but few studies specifically address how coping changes across developmental levels.

Nevertheless, when research on regulation and coping is integrated, it is clear that there are several broad developmental phases characterized by different mechanisms of regulation. Infancy begins with stress reactions governed by reflexes, soon to be supplemented by coordinated action schema. For example, infants become able to display more differentiated emotions and coordinate these with actions that can soothe distress, such as reaching for a caregiver or a favorite toy. During toddlerhood and the preschool years, coping is increasingly carried out using direct actions; this is the age period at which voluntary coping actions first appear. That is, although children may have difficulty using cognitive coping strategies, toddlers and young children develop behavioral methods for alleviating distress, such as pretend play and behavioral distraction. During middle childhood, coping through cognitive means solidifies, as described in work on distraction, delay, and problem solving. Children's thoughts about positive things (cognitive distraction) provide comfort, and they can work through possible responses to a problem without enacting them. By adolescence or early adulthood, coping through metacognitive means is added, in which youth become increasingly capable of regulating their coping actions based on future concerns, including long-term goals and strategies to prevent or avoid subsequent stress.

At the same time, these broad developmental phases are characterized by changes in the participation by social partners. Starting at birth, other people, especially sensitive and responsive caregivers, are a fundamental part of the neonate stress reactivity system, influencing not just how infants

respond but whether they even physiologically register an event as stressful. During this period, caregivers carry out coping actions based on their reading of the stress responses of their infants. During toddlerhood and preschool age, as children become more self-reliant, they can more intentionally enlist the participation of social partners. For example, they can physically seek out others when distressed, and they can use emotions and language to advertise their needs for help. Social partners participate actively with children as they deal with challenges and threats, and their mere presence may support more adaptive coping. During middle childhood, children are increasingly self-reliant and able to coordinate their coping efforts with those of others, although social partners remain key backups. By adolescence, children can deal with a variety of normative stressors on their own, but they selectively rely on others for help and advice. Youth are increasingly capable of regulating their coping actions based on their effects on others. Hence, one of the most interesting developments in coping is how the use of social support seeking changes with age.

Development of Seeking Social Support

Support seeking can be considered an all-purpose adaptive family of coping strategies, commonly called upon by people of all ages to deal with all kinds of stressors. Support seeking, which includes seeking emotional support, comfort, help, information, or advice, is the most commonly used coping family among infants, toddlers, children, and adolescents. However, it is still possible to discern typical (i.e., average) patterns of support seeking that change with age. For example, infants quickly progress from generalized expressions of distress that bring a caregiver to their aid to intentional appeals (through focused gaze or vocalizations such as crying) to caregivers for aid, attention, and information. Infants also are sophisticated at looking to others for cues about responses to stress (i.e., social referencing), which can diminish negative stress reactions or ease distress.

Starting at about age 4, decreases in seeking support from adults are the rule, especially during the 5-to-7-year shift and the transition to adolescence (ages 10–12). At the same time, children and adolescents report greater preferences for self-reliance

and peer support as they get older. Hence, declines in seeking support from adults are found during the late childhood and adolescent years. These decreases are accompanied by increases in self-reliance and in attempts at problem solving and seeking peer support (especially emotional support).

Stressors that are uncontrollable and over which adults have authority (e.g., medical stressors) are one exception to this pattern; for these events, children show increasing preferences for seeking adult support as they get older. This is part of a general shift across ages 10 to 16, during which children become better able to determine who would be the best source of support for dealing with specific kinds of stressors rather than relying on support from caregivers for most of their informational and emotional support. Taken together, these trends suggest that individuals are more organized and selective in their use of social support as a coping strategy as they get older; they seek out support that will meet their particular needs at the time and use few or multiple sources of support depending on their distress, self-reliance, and other needs.

Social Influences on the Development of Coping

It is almost impossible to overstate the importance of social relationships (including parents, siblings, extended family members, friends, peers, teachers, classmates, and neighbors) to children's coping. Social partners play a role in determining the stressors, both chronic and acute, to which children will be exposed; partners' problems can become stressors for children; social partners contribute to the development of children's coping resources, such as self-efficacy or social skills; they shape children's stress reactivity, for example, through quality of attachment; social partners participate in children's coping, through their own stress reactivity (e.g., panic or blame) and coping actions; and social partners help children learn from bad experiences, including planning proactive coping to prevent their reoccurrence. Research on attachment, social support, parenting, family processes, peer relationships, teaching, and parent-child interactions have all shown links between the availability of supportive relationships and children's reactions to stress, regulation, and coping.

Nowhere is the importance of interpersonal relationships seen more clearly than in research on how parenting influences the development of coping. Parents socialize coping explicitly through modeling, teaching, and coaching. Moreover, they also shape children's coping implicitly through availability, involvement, comforting, soothing, and helping. Family climate and parenting style play a role in the ways that children learn to cope with stress. For example, parents who are more warm and involved, who provide clear and consistent guidelines, and who assist their children to make their own age-appropriate decisions have children who are lower in negative emotionality and who use more active coping behaviors, such as problem solving and direct action. Children who grow up with such positive parent-child relationships also report less avoidant coping responses when dealing with stress and have better mental health outcomes when stress does occur. Similar results have been found for teacher-student relationships and children's coping with academic stress.

Research is just beginning to explore exactly how social forces shape children's coping. One guide for organizing this research is the idea that social partners shape children's coping by facilitating or impeding the development of children's regulatory resources and how they are deployed under stressful conditions. An intriguing direction in this work is that the kinds of parent behaviors that are effective in promoting the development of adaptive coping and regulation depend on children's temperamental characteristics. For example, a child who has a temperamental tendency to be overcontrolled (e.g., inhibited, anxious, or shy) will benefit from parenting strategies that include high levels of modeling and supported behavior as the child slowly attempts to add to a repertoire of adaptive coping strategies while managing high arousal. In contrast, a child who has a tendency to be undercontrolled (e.g., high impulsivity) may require a different kind of parental availability, which includes coaching the child to stop to think about alternative coping strategies before acting and involves more direct action to repair situations when a child's coping actions go awry.

Future studies can use research on parents as a template for studying the effects of other adult social partners, such as grandparents, aunts and uncles, teachers, coaches, and neighbors. The

effects of other children and youth, such as siblings, peers, friends, and classmates, may take different forms or additional pathways. In every case, it is important to remember that the mere existence of supportive others can have an enormous impact on experiences of stress and processes of coping.

Conclusion

Patterns of coping with stress are diagnostic of the entire human system of which it is part—adaptive coping reveals that demands are developmentally appropriate, social resources are sufficient, and individual capacities are well developed. Moreover, coping is more than a symptom. It is a player in processes of risk and resilience. Coping, because it describes the ongoing transactions between humans and the demands present in daily life, can be considered a proximal process—that is, a major driver of development. How a toddler, child, adolescent, or adult deals with the normative stressors he or she encounters at home, at school, at work, and in the neighborhood plays a decisive role in the ongoing development of appraisals of stress, coping resources, and vulnerabilities. This is especially true for children and adolescents, but stress and coping likely play significant roles in emotional, social, cognitive, and personality development all across the life span.

COUPLE IDENTITY

As close relationships progress over time, relationship partners may develop a couple identity and begin thinking of themselves as part of a couple rather than as separate individuals. Couple identity is at least somewhat consciously accessible, involving a sense of overlap with one's partner and the perception of the self and partner as a team or collective unit. Couple identity may also operate automatically and outside of conscious awareness. For instance, people with a strong couple identity are more likely to spontaneously use plural pronouns (we, us, ours) instead of singular pronouns (I, me, mine) when talking about their relationships. This entry discusses the nature of couple identity, how it develops, and its implications for individuals and their relationships.

Couple identity frequently manifests itself in observable behaviors and aspects of the couple's shared environment that reflect the blurred boundary between self and partner. Close relationship partners often share a social environment of mutual friends and engage in shared interests and activities together. They may cohabit, merging their possessions and creating a shared physical environment. They may even share bank accounts. Close relationships are often characterized by reduced

personal borders, as revealed by frequent touching, sharing food, and close physical contact.

Couple identity also influences information processing in that information about close relationship partners tends to be processed similarly to information about the self. For instance, cognitive biases that normally favor the self over others are attenuated for close relationship partners, presumably because the formation of a couple identity minimizes the distinction between oneself and one's partner. Individuals with a strong couple identity tend to respond to a partner's successes and failures as their own. Evidence also suggests that mental representations of the self overlap with those of close partners. For instance, people are faster at judging whether a trait describes the self if it also applies to a close partner than if it does not, suggesting that shared traits are more accessible to the self-concept. Other research suggests that individuals make inferences about their own attributes by observing the behavior of others with whom they have a sense of merged identity. Close relationship partners even tend to encode, store, and retrieve information from each other as though they are drawing on a shared memory system.

Development of Couple Identity

Couple identity is positively correlated with relationship length and develops gradually over time as relationship partners grow closer and more committed. Research suggests that couple identity is not just an outcome of commitment, but that commitment and couple identity influence each other in a cyclical pattern. That is, commitment is associated with changes over time in couple identity, and couple identity is associated with changes over time in commitment. Arthur and Elaine Aron's Self-Expansion Model argues that as a relationship develops, the resources, perspectives, and identities of one's partner are to some extent experienced as one's own and thus included in one's sense of self. As a result, the individual experiences a sense of closeness or overlap with the partner and treats the partner similar to the self. This merging of self and other is theorized to emerge from the interdependence and correspondence of outcomes that characterize close relationships—partners tend to mutually influence

each other, and one partner's good or bad news may strongly affect the other.

In addition to relationship-specific couple identities, people also differ in the degree to which they generally define themselves in terms of their close relationships rather than their unique personal attributes. Not surprisingly, this chronic tendency to define oneself in terms of close relationships is associated with a greater likelihood of developing a couple identity within a particular relationship. Several studies have found gender differences in this tendency: women are slightly more likely than men to chronically define themselves in terms of their relationships and spend more time thinking about their relationships. These gender differences are generally small, and there are members of both genders with relatively strong and relatively weak couple identities.

Relational Implications

In addition to being more committed, men and women with strong couple identities tend to be more satisfied with their relationships and are less likely to break up or divorce. Couple identity predicts greater positive relationship thinking, which is thought to increase the likelihood that an individual will act in ways that benefit the partner or relationship rather than just the individual's own immediate self-interest. One study found that for males, couple identity was associated with viewing sacrifice for the partner as more satisfying and less harmful to the self. To the degree that a strong couple identity allows one to share a partner's perspective, it is also likely to facilitate conflict resolution and result in more charitable explanations of a partner's behavior. For example, a study of married couples found that both husbands and wives with strong couple identities became less physiologically aroused and showed less contempt and belligerence while talking to their spouses about problems in the marriage. Recent research has also examined the role of couple identity in coping with stressors. One such study found that couple identity helped minimize the negative mental health outcomes associated with caring for a chronically ill partner. In addition to these correlational findings, several studies have established that manipulating couple identity influences other

relationship variables. For instance, individuals asked to talk about their relationship using plural pronouns rated their relationship as more intimate, important, and close than individuals asked to use singular pronouns. In fact, some forms of couple therapy attempt to cultivate the sense of couple identity in the hope that this shared sense of identity would facilitate other positive changes in the relationship.

Although the formation of a couple identity is generally conceived of as an expansion of one's individual identity to include a partner, psychodynamic and feminist theorists have argued that entering a close relationship may sometimes lead to the loss of one's individual identity, particularly if one's individual identity is poorly developed or one feels compelled to sacrifice important aspects of the self to maintain the relationship. Others have argued that there is an optimal level of couple identity and that exceeding this level may result in feeling too close to a partner. Couple identity may also have detrimental consequences when a relationship ends and the individual loses aspects of the self that were previously defined through the relationship, potentially resulting in a sudden retraction of the identity. One study of women who had lost a spouse through either death or divorce found that women who reported a strong couple identity after the loss experienced greater psychological distress and disruption in their sense of self. Despite these negative implications, a growing body of research supports the conclusion that couple identity is both an important outcome and causal agent in the positive development of close relationships.

COUPLES IN LATER LIFE

In later life, persons continue to desire and form intimate relationships that afford love, companionship, and physical intimacy. These relationships have diversified in recent decades. Older persons still may marry or remarry, but increasingly they are entering into dating, cohabiting, and living apart together (LAT) relationships instead. This entry describes these relationships; examines how experiences in these relationships differ by gender, race/ethnicity, and sexual orientation; and discusses the consequences of these relationships for well-being.

General Influences on Couples' Relationships

In all types of relationships, persons strive to balance their needs for love, companionship, sex, and emotional and financial security with needs for autonomy and independence. Their ability to do so is influenced by social inequalities, such as gender relations. The term *gender relations* refers to inequalities of wealth, authority, labor, and esteem, supported by ideologies that justify men's greater privilege in most settings. Among today's older couples, for example, men tend to control finances and decisions (except mundane ones), and women tend to maintain social networks and provide domestic labor, including care work. Gender inequality is lessened over time, however. Gender relations combine with inequalities of race/ethnicity and sexual

orientation to shape couples' experiences in later life. In addition, persons' past and present circumstances influence their choices to pursue particular intimate relationships.

Marriage

Among those age 65 and over, marital status has changed little since the 1970s. The percentage of women married has risen slightly due to longer life expectancy for all, and more recently for men. Asians/Pacific Islanders and then Whites are the most likely to be married, followed by Hispanics, Native Americans, and Blacks. Men of all races are more likely to be married than are women of any race.

Most couples in long-term marriages have relatively high marital satisfaction, regardless of whether they share interests and values or lead more independent lives. Some, however, have emotionally distant independent relationships and low marital satisfaction. Overall, older men are more satisfied with their marriages than older women are. Older wives, but not older husbands, are more satisfied with marriage when they share decision making equally. Both husbands and wives mention leisure activities and intimacy (sex and communication) as areas of disagreement. Women are more likely than men to mention personal habits and health matters; men are more likely to mention financial matters or to say their relationship has no problems. Finally, older Blacks report more marital conflict than do older Whites, and older Black women report lower marital satisfaction than do White women (partly because of greater financial strain).

Experiences common to later life, such as retirement or caregiving, do not seem to make late-life marriages more equal. For instance, despite White women's increased labor force participation, the division of domestic labor among retired persons remains traditional. Men who increase their domestic labor usually do more stereotypically masculine tasks, unless their wives are disabled. Even when men choose to perform such traditionally feminine tasks as cooking, their wives retain ultimate responsibility. Notably, while both Black and White wives do more domestic labor than their husbands, African Americans divide domestic

labor more equally and flexibly over the life course.

Spousal caregiving may not change the balance of power either, even if husbands or wives take on gender-atypical tasks. Caregiving spouses usually must perform the other's tasks, and caregiving husbands provide the same amount and type of personal care as wives do. Traditional gender relations can persist, however, depending on the nature of the illness. For instance, among husbands and wives with physical impairments, wives receiving care express gratitude because they are aware of the labor involved. By contrast, husbands receiving care are more demanding and difficult. Not only are they less aware of the labor involved, but they also seek to remain the head of the household and to exert more control.

Gender relations and race influence the benefits of marriage. Being married often provides financial security, especially for White women, given White men's higher income and retirement benefits. Marriage benefits older men's and women's mental and physical health because spouses encourage healthier behavior. But it benefits men's physical health more because women's caretaking roles make them more likely to engage in self-care and encourage their husbands to make lifestyle changes and follow doctors' advice.

Wives also do more to help keep husbands socially integrated because women provide more emotional support and do more kinkeeping (i.e., maintaining contact with children, other relatives, and friends). Husbands rely solely on wives as confidants more than the reverse. Hence, married men have more social interaction both within and outside the home than widowed, divorced, and never-married men. Divorced men in particular tend to have attenuated social networks, less close relationships with their children, and less interaction with neighbors and others because they often move after divorce.

Race, too, influences how much social integration marriage provides. African-American husbands tend to have less informal social support in later life than their wives if they previously were divorced because divorce often severs men's family ties. African-American men who are married to their children's mother have larger networks that include their children and other kin.

Remarriage

Remarriage is uncommon in later life in the United States and throughout the Western world. Rates of remarriage in later life are low because of declining health, financial problems, lack of need to marry for childbearing and childrearing, a desire to protect one's inheritance or estate, and unwillingness to relocate. Remarriage is more common after divorce than after widowhood. Men are more likely to remarry than women are. Because women live longer than men, men have more opportunities to meet potential mates, whereas women face a shortage of available, healthy partners. Remarriage rates also are higher at younger ages for Whites and for persons with higher incomes.

Gender and race influence desire and motivations for remarriage. Overall, widowers express more interest in remarrying than do widows, and they have different motivations for doing so. Widowed men and women alike tend to be lonely. Nevertheless, because women generate more support from kinkeeping and other activities, they are less depressed and less motivated than men to remarry for emotional support. Many widows are reluctant to remarry because of the burden of domestic labor and care work that remarriage can entail, preferring their newfound freedom instead. Older cohorts of men, in contrast, are motivated to remarry because they lack domestic skills. Having a readily available sex partner also tends to be more of an incentive to remarry for men than for women. Widowers who express disinterest in remarriage often do so because they realize their advanced age and poor health make them less marriageable.

By contrast, because widows are more vulnerable to poverty than widowers, they are more motivated to remarry for economic security. Remarriage, however, can mean the loss of income related to the deceased spouse. Black women are less likely than White women to remarry for economic security. In old age, some Black women see remarriage as entailing financial burdens. In addition, Black women are raised to be more economically independent than White women, and they view their economic security as less dependent on marriage.

Older adults, especially women, may be uninterested in late-life marriage but may still want a long-term, intimate relationship. Dating, cohabitation,

gay and lesbian relationships, and LAT relationships are alternatives.

Dating

The percentage of older persons in dating relationships declines with age. Older women are far less likely to date than are older men, mostly due to the lack of available partners. Primary motivations for dating in later life are companionship and intimacy. In seeking dating partners, older men and women alike want a pleasing personality, sense of humor, common interests, and moral values. In line with contemporary gender relations, women are more likely than men to want a financially secure partner who practices a religion. Men are more likely than women to seek sexual satisfaction and physical attractiveness. Regarding rewards from dating, men are more likely to cite intimacy and emotional support, and women are more apt to mention status. Gender differences seem to be slowly eroding. For example, dating scripts among older persons have changed in recent years: Although women like men to initiate dates, they prefer to meet their dating partners in public places and to pay their own way.

Not surprisingly, widowers express greater interest in dating than do widows, especially if they lack adequate social support. Dating appears to benefit mental health. Widows and widowers who are involved in a dating relationship report fewer depressive symptoms than those who are not.

Cohabitation

Cohabitation has increased across all age groups in recent decades, but is still rare among persons aged 65 and older. Some older women prefer cohabitation to marriage, because it tends to be more equitable. Compared to younger cohabitators, middle-aged and older cohabitators view their relationships as fairer and more stable, spend more time together, argue less often, and are more likely to view their relationship as an alternative rather than a prelude to marriage.

Cohabitation appears to provide fewer mental health benefits than marriage, especially for men. Compared to older married persons, older cohabitators report more depressive symptoms. Partly this is

because they tend to have fewer financial resources, less social support, and poorer physical health. When these factors are taken into account, cohabiting and married women have similar levels of depressive symptoms, but cohabiting men still have more depressive symptoms than married men.

Gay and Lesbian Relationships

Gay and lesbian relationships are alternatives because marriage is not usually possible. Overall, older gay men and lesbians value couple relationships but experience difficulty finding partners with advancing age. Couple relationships among gay men and lesbians reflect the high values they place on egalitarianism and friendship, as well as on independence. The lack of social legitimacy afforded gay and lesbian couple relationships can produce unique stressors, such as limited support from family, or tensions, such as one partner's reluctance to publicly acknowledge the relationship.

Gender relations also shape gay and lesbian couples' experiences. For instance, in line with more feminine ideas about love, lesbians tend to prefer monogamy, whereas gay men do not. In later life, though, gay men increasingly prefer committed, monogamous relationships. Gays and lesbians in committed, monogamous relationships are happier than those not in such relationships. Long-term relationships, while less prevalent, are equal in quality to those of heterosexuals.

LAT Relationships

LAT relationships are long-term, committed relationships in which partners maintain separate dwellings. This arrangement, common in Northern and Western Europe, is emerging in the United States. Like marriage, LAT relationships are based on love and attraction, and they provide intimacy and emotional support. Because persons in LAT relationships typically do not pool resources or meld their family networks, they can have both intimacy and autonomy while protecting their children's inheritance.

Women are especially interested in LAT relationships because they lose less autonomy than they typically would in a more conventional relationship. By maintaining their own residence,

women can resist performing domestic labor for partners, keep their own routines, and sustain relationships with friends and family apart from their partners if they choose.

COUPLES IN MIDDLE AGE

Marriage (and marriage-like relationships such as long-term cohabitation, gay unions) is perhaps the most important interpersonal relationship across the adult life span. Marital relationships are not static but dynamic; they change as the individuals

in them grow older. Research on long-term marriages shows that as people age, their marriage continues to provide emotional support and to act as a valuable source of positive feelings. New life transitions, however, can bring new responsibilities that, in turn, can have a cascading influence on the quality of the marriage. This is perhaps most true of the middle adulthood years, a period during which it is not unusual for individuals to experience important personal life transitions (e.g., menopause or an empty nest) and to occupy new roles (e.g., providing care to an ill or disabled parent or becoming a grandparent). This entry focuses on marriage during the middle adulthood years and examines the quality of marital relationships, factors that play a role in shaping marriage, and the role of marriage in the health domain during this life stage. Although most of the research on long-term intimate relationships has focused specifically on marriage between heterosexual adults, it is likely that the issues discussed here also pertain to other midlife couples such as long-term cohabitators and gay and lesbian partners.

Conceptualization and Measurement of Marital Quality

Although marriage as a social institution is widespread in the United States, measuring the quality of marriage remains a formidable challenge because researchers have difficulty in achieving a consensus definition of marital quality. Early on, some researchers focused on marital satisfaction or marital adjustment as indicators of the quality of a marriage, while others focused on more negative dimensions such as marital disagreement and marital conflict. Today, marriage researchers widely accept that people routinely experience both positive and negative feelings about their marriage. At a minimum, then, marital quality is a two-dimensional construct incorporating both positive processes (e.g., happiness or satisfaction) and negative processes (e.g., level of disagreement or conflict). Researchers can choose from among several different scales to measure marital quality and its different dimensions. Some of these scales measure specific behaviors that occur in marriage (e.g., “How often do you and your partner quarrel?” or “Do you kiss your spouse?”), whereas

others include more global and evaluative items regarding one’s marriage (e.g., “All things considered, how happy are you with your marriage?”).

Marital Quality in Middle Adulthood

Studies comparing positive dimensions of marital quality (e.g., marital satisfaction, marital happiness) across young, middle-aged, and older adults have found support for a U-shaped trend with marital satisfaction and happiness lower among middle-aged adults compared to those who are younger or older. However, longitudinal studies spanning extended periods of time have found that marital satisfaction and happiness typically decline after the newlywed years and into middle adulthood and then either stabilize or continue to decline after midlife.

Researchers have tried to uncover underlying reasons for the dip documented in the positive evaluation of marriage during middle adulthood. Some have attributed this dip to having and rearing children, inequities in household responsibilities, and conflicting demands due to multiple roles (e.g., balancing work and family demands, being sandwiched between assisting one’s children and one’s aging parents). Others have identified strained relationships with one’s children and midlife identity issues as contributing to the drop in positive marital processes in middle adulthood. Sexual intimacy and sexual satisfaction also play an important role in positive evaluations of marriage at midlife. Higher sexual satisfaction is related to greater marital satisfaction that, in turn, is related to lower marital instability in both husbands and wives. Women, in particular, experience changes in sexual response and sexual desire at midlife due to the menopause-related physiological changes they undergo. Middle-aged women’s marital satisfaction is linked to greater enjoyment of sexual activity with the spouse, higher rated pleasantness of sexual activity, and greater overall satisfaction with the sexual relationship in marriage.

Trends in negative marital processes over the life course generally show that middle-aged and older persons report less marital conflict than young adults do. It is important to keep in mind, however, that declining trends in marital conflict may be illusory as the most conflictual marriages are likely

to have ended in separation or divorce prior to middle age. Moreover, a declining trend does not mean that marriages at midlife are free from conflict. Indeed, marital disagreement and heated arguments are not altogether absent from marriage at midlife, and in some cases, middle-aged adults report levels of negative marital processes comparable to those of their younger counterparts. In terms of resolving marital conflicts, middle-aged adults tend to be more emotionally negative and less affectionate than their older peers.

Researchers have found that the most common area of disagreement between spouses during the midlife years centers on the couple's children. Middle-aged parents' problematic relations and conflict with their adult children are related to greater marital conflict at midlife. Another important contributor to marital conflict in middle adulthood is spouses' (dis)satisfaction with the division of household labor. At midlife (and throughout the family life cycle), women are less satisfied than men with the division of household labor. This dissatisfaction with division of household labor is related to greater marital conflict (as well as lower marital happiness) for both women and men.

Marriage and Midlife Transitions

Midlife is typically marked by numerous changes including children leaving the home (i.e., the empty nest), adult children returning to live at home, taking on the caregiver role for an ill parent or parent-in-law, and for women, menopause. Although early cross-sectional research reported lower levels of marital happiness immediately following the departure of children from the home, more recent longitudinal research indicates that the empty nest is associated with significant increases in marital happiness, especially soon after the children leave. Although the passionate type of love for one's spouse tends to be lower during the empty nest phase compared to the earlier phases of marriage, this difference in absolute terms is small and passionate love is far from absent during midlife. As a matter of fact, the return of adult children to their parents' home can have a detrimental impact on their parents' marital satisfaction, especially for parents whose children make more frequent returns to the parental home.

Nevertheless, the empty nest transition can be a risk factor for marital disruption in the form of separation or divorce. Data from a U.S. sample of middle-aged women found this to be the case for those who married at a younger age, did not own their home, had marriages of shorter duration, and were employed during the empty nest transition. Indeed, divorce during the middle-adulthood years has been on the rise in recent decades. A recent survey found that during the midlife years divorce is often initiated by women, with men often being caught by surprise by their divorce. The most common reasons for divorce after long-term marriages include some form of abuse (verbal, emotional, or physical), differences between spouses in terms of values or lifestyles, and infidelity.

For midlife women, menopausal changes tend to make this period of transition especially significant. A study on the relationship between menopause and marriage found that nonmarried women reported more feelings of depression than married women during the menopausal years. However, among married women, those who were less satisfied with their marriage reported more negative moods than women who reported moderate or higher marital satisfaction. Middle-aged women also quite commonly find themselves sandwiched between two forms of care provision—supervising their teenagers and caring for a parent or parent-in-law. Studies show that taking on the added role of caregiver to one's parent can be quite challenging for middle-aged married women who also are employed and have responsibilities for their own children. Studies also show that caring for an ill or frail parent is related to less marital satisfaction during the middle-aged years, especially among those who have been long-term caregivers.

Marriage and Health at Midlife

Several studies have linked being married and, more specifically, being in a good marriage with better physical and mental health during the midlife years. Being married during the midlife years is linked to greater psychological well-being, more health protective behaviors, fewer physical illnesses, better physical functioning, and fewer physician visits and hospital stays compared to being divorced, widowed, never married, or casually

dating. Being married also is linked to greater longevity in the second half of life compared to other marital statuses. A recent longitudinal study on the relationship between marital history in middle adulthood and longevity found that those who were consistently married at midlife lived longer (over a follow-up period of approximately 40 years) than those who had experienced marital disruption even if the latter had remarried by middle adulthood. In general, the protective effects of being married on mortality are stronger for men than for women.

Although being married is associated with multiple health benefits, the quality of the marriage also plays an important role in shaping health at midlife. Greater marital disagreement is related to more feelings of depression as well as diagnoses of clinical depression during middle adulthood. The link between marital disagreement and feelings of depression is stronger for middle-aged adults than for their younger counterparts. Also, higher levels of marital disagreement are associated with higher risk for excessive alcohol use at midlife. A poor quality marriage contributes to poorer physical health as well. In a study of middle-aged women, researchers found that women in high-satisfaction marriages had better heart health than both those in low-satisfaction marriages and those not currently married. Moreover, negative behaviors displayed by the spouse (e.g., criticism, hostility) are associated with more physical symptomatology, more chronic illnesses, poorer physical function, and worse self-reported physical health among middle-aged adults.

The health benefits of long-term marriage are not uniform for women and men. Among wives—but not husbands—higher marital satisfaction is related to better psychological and physical health. Whereas wives receive health benefits from marriage only if they are in a happy marriage, husbands gain health benefits merely from being married. Research also shows that the link between marital conflict and physiological changes (e.g., increased blood pressure, compromised immune function) is stronger and longer lasting for women than for men. Women may be more sensitive to marital conflict than men and may be exposed to more marriage-related stress by experiencing greater family demands and contributing disproportionately more time and effort to household responsibilities than men.

In sum, marriage (or a marriage-like relationship) remains an important source of emotional support and positive feelings during middle age. Marital satisfaction typically dips during the midlife years and although not free from disagreement, marriages become less conflictual. Midlife transitions play a significant role in shaping the quality of marriage during midlife, quality which in turn plays an important role in health.

COUPLE THERAPY

Couple therapy refers to a diverse set of interventions provided to partners in an intimate relationship; it is intended to reduce various aspects of relationship distress and promote relationship satisfaction and well-being. Couple therapy typically is provided to partners in conjoint sessions (i.e., both partners meeting simultaneously with the same therapist). Couple-based interventions targeting relationship distress may be delivered not only to married heterosexual couples, but also to cohabiting or same-gender couples as well as to those in which partners live separately.

Couple therapy comprises an essential component of mental health services—emerging partly in response to a divorce rate of approximately 50 percent for first marriages in the United States. By far the most frequently cited reason for seeking mental health services is relationship difficulties. In addition to the high prevalence of couple distress in both clinical and community samples, the adverse impact of couple distress on both the emotional and physical well-being of adults and their children has contributed significantly to the increased stature of couple therapy as a component of mental health services. Although couple therapy most often aims to reduce overall relationship distress, couple-based interventions have also been developed to treat couples in which one or both partners struggle with individual emotional or behavioral disorders.

This entry provides an overview of basic objectives of couple therapy and brief descriptions of empirically supported approaches to treating relationship distress. Evidence supporting couple-based interventions for specific problems (e.g., sexual difficulties, substance abuse, physical aggression, infidelity) is summarized along with findings regarding predictors of treatment outcome.

Objectives of Couple Therapy

In general, couple therapy targets those individual and relationship characteristics that have been shown to differentiate distressed from nondistressed couples. For example, distressed couples are distinguished by (a) higher rates of negative

verbal and nonverbal exchanges (e.g., disagreements, criticism, hostility); (b) higher levels of reciprocity in negative behavior (i.e., the tendency for negativity in one partner to be followed by negativity in the other); (c) lengthier chains of negative behavior once initiated; (d) higher ratios of negative to positive behaviors, independent of their separate rates; and (e) lower rates of positive verbal and nonverbal behaviors (e.g., approval, empathy, smiling, positive touch). Distressed couples are also more likely than nondistressed couples to demonstrate a demand-withdraw pattern in which one person requests changes in behavior from the other partner and that partner withdraws, with the partners' respective approach and retreat behaviors progressively intensifying. Couples have higher long-term risk for distress or relationship dissolution when one or both partners exhibit criticism or contempt for the other or respond with defensiveness or withdrawal in response to disagreements.

Distressed partners also show a disproportionate tendency to blame each other for problems and to attribute each other's negative behaviors to broad and stable traits. For example, an argument about money late in the evening may be attributed to the other person's selfishness rather than to fatigue or an unexpected large bill that arrived earlier in the day. Distressed couples are also more likely to have unrealistic standards and assumptions about how relationships should work and lower expectancies regarding their partner's willingness or ability to change their behavior in some desired manner. Finally, consistent with findings regarding negative behaviors, distressed couples are distinguished from nondistressed couples by higher overall rates, duration, and reciprocity of negative emotions and, to a lesser extent, by lower rates of positive emotions.

The various approaches to couple therapy differ in their relative emphasis on these behavioral, cognitive, or emotional aspects of couples' functioning. However, nearly all approaches to couple therapy share the following common goals: (a) providing a safe environment in which relationship difficulties can be communicated and negotiated; (b) increasing mutual acceptance; (c) ameliorating individual and relationship crises; (d) improving communication, including decision-making skills as well as emotional expressiveness and responsiveness;

(e) building partners' friendship and emotional bonds; and (f) improving sexual and other physical intimacy.

Approaches to Couple Therapy

Numerous studies have demonstrated that couple therapy produces moderate, statistically significant, and often clinically significant effects in reducing couple distress. A meta-analysis of these studies indicated that the average person engaged in couple therapy was less distressed at termination than 80 percent of individuals who received no treatment. Moreover, when compared to alternative treatment modalities such as individual therapy and medical interventions, the mean effect size for couple therapy was generally comparable or larger.

Although the literature describes numerous theoretical approaches to couple therapy, only six have garnered empirical evidence of their effectiveness in controlled clinical trials. Traditional Behavioral Couple Therapy (TBCT) is a skills-based approach targeting decision-making communication as well as an increase in positive and decrease in negative behavior exchanges. TBCT has been studied more extensively than any other single approach to couple therapy, with findings indicating that the average individual receiving TBCT is better off at the end of treatment than 72 percent of individuals not receiving treatment. However, follow-up studies of TBCT indicate that approximately 30 percent of couples who initially improve in response to therapy subsequently show significant deterioration in the first 2 years after termination.

Cognitive Behavioral Couple Therapy (CBCT) builds upon TBCT by incorporating interventions targeting partners' relationship assumptions and standards, expectancies, and attributions that contribute to or maintain distorted emotions or maladaptive behaviors underlying couple distress. Initial studies of CBCT demonstrated effectiveness comparable to findings for TBCT. Various adaptations of CBCT have since been developed and shown to be efficacious for treating couple distress related to a variety of physical health and emotional or behavioral disorders.

Integrative Behavioral Couple Therapy (IBCT) goes beyond CBCT in emphasizing interventions

aimed at increasing acceptance by promoting tolerance and encouraging partners to appreciate differences and to use these to enhance their relationship. A large randomized clinical trial comparing IBCT with TBCT showed that both treatments produced clinically significant improvement by the end of treatment; 71 percent of IBCT couples and 59 percent of TBCT couples were reliably improved or recovered, based on self-reports of overall relationship satisfaction. At 5-year follow-up, separation and divorce rates for couples in the two treatment conditions were virtually identical at slightly over 25 percent.

Three approaches to couple therapy from non-behavioral perspectives have also garnered evidence of their effectiveness. Emotionally Focused Couple Therapy (EFCT) builds on an attachment perspective of adult intimacy and targets cyclical, self-reinforcing interactions that hinder secure, trusting bonds. In four randomized trials, EFCT was superior to a waiting-list control condition in reducing relationship distress, yielding improvement rates of 70 to 73 percent. Another approach, Integrated Systemic Couple Therapy (ISCT) seeks to disrupt repetitive, self-perpetuating negative interactional cycles by changing the meaning attributed to these cycles. In a clinical trial comparing ISCT with EFCT, both were found to be superior to a control condition and to be equally effective in alleviating couple distress; however, ISCT couples showed greater maintenance of gains at 4-month follow-ups in relationship satisfaction and goal attainment.

Finally, an insight-oriented couple therapy (IOCT) was compared with TBCT in a controlled clinical trial involving 79 distressed couples. The insight-oriented condition emphasized the interpretation and resolution of conflictual emotional processes related to developmental issues, collusive interactions, and maladaptive relationship patterns. Couples in both treatment conditions showed statistically and clinically significant gains in relationship satisfaction compared to a waitlist control group. However, at 4-year follow-up, 38 percent of the behavioral couples had experienced divorce, in contrast to only 3 percent of couples in the insight-oriented condition.

Despite the overall effectiveness of couple therapy, aggregate findings across the six empirically supported treatments indicate that a substantial

percentage of individuals fail to show improvement from these treatments; moreover, among those individuals who initially respond favorably to couple therapy, approximately 30 to 60 percent subsequently evidence significant deterioration. Such findings have led to development of integrative models of couple therapy incorporating the most effective elements of diverse treatment approaches. A depth-behavioral approach to Integrative Couple Therapy incorporates both behavioral therapy and object relations therapy, based on the premise that couples' interpersonal and intrapersonal worlds both need attending to and that partners must broaden their perceptions of interpersonal contact by exposing those aspects of themselves that are blocked from conscious awareness. An alternative pluralistic approach espouses a hierarchical approach to couple therapy incorporating behavioral, structural, and cognitive techniques earlier in therapy and insight-oriented techniques later in treatment if the couple distress is resistant to change earlier in therapy. The insight-oriented component of this pluralistic approach, labeled *affective reconstruction*, examines each partner's previous relationships to identify maladaptive patterns and ways in which coping styles established in previous relationships may obstruct emotional intimacy in the current relationship. Neither of these integrative approaches to couple therapy has been examined empirically, although both approaches build on techniques supported by previous research.

To date, there are no replicated studies that consistently favor one of these empirically supported couple therapy approaches over another. However, couple therapy will likely be more effective when rendered by therapists who are theoretically grounded and technically competent in diverse approaches and who can draw upon specific interventions from these different perspectives in a conceptually congruent manner.

Couple Therapy Targeting Specific Problems

Although the most frequent application of couple therapy is for reducing overall relationship distress and promoting couple well-being, couple-based interventions have also been developed for treating specific relationship problems and individual disorders shown to covary with couple distress.

For example, research indicates that individuals reporting moderate or higher global relationship distress are 5 to 6 times more likely than nondistressed persons to report problems in the areas of physical aggression, sexuality, finances, and childrearing. Moreover, persons in distressed intimate relationships are 2 to 3 times more likely than nondistressed persons to experience disorders involving mood, anxiety, or substance abuse.

The co-occurrence between overall couple distress and specific individual or relationship problems has led to three couple-based treatment strategies for addressing these comorbid difficulties. The first uses general couple therapy to reduce overall relationship distress based on the premise that relationship conflict serves as a broad stressor that contributes to the development, exacerbation, or maintenance of specific individual or relationship problems. The second strategy involves disorder-specific couple interventions that focus on particular partner interactions presumed to directly influence either the co-occurring problems or their treatment. The third couple-based strategy involves partner-assisted interventions in which one partner serves as a surrogate therapist or coach in assisting the other partner with individual problems.

Sex therapy is the treatment of choice for couples experiencing sexual difficulties. Treatment for sexual difficulties includes assisting couples conjointly in discussing and resolving specific challenges in their sexual interactions. Couple-based interventions have improved sexual functioning for women with orgasmic disorders at rates ranging from 65 to 90 percent. However, couples receiving couple therapy in addition to sex therapy demonstrate more pronounced and comprehensive treatment gains, including significantly more intense experiences of sex and sexual desire.

Physically violent couples are especially difficult to treat and require special attention to the safety of the partner(s) targeted by the violence. Couple-based interventions emphasizing anger management and communication skills have been effective in treating couples experiencing mild to moderate levels of physical aggression; however, most clinicians agree that couple therapy is inappropriate for couples characterized by severe physical aggression; for such couples, individual treatment for the aggressive partner is recommended. One finding suggests that the most effective venue for treating

mild to moderate relationship aggression is a multicouple group format of couple therapy.

Specific intervention strategies can be effective for couples struggling to recover from infidelity, particularly to address issues surrounding trust and forgiveness. Until recently, there has been almost no empirical study of interventions for couples dealing with affairs despite that couples report infidelity as a leading cause of divorce and therapists describe it as one of the most difficult problems to treat. A recent integrative approach for treating affair couples emphasizes three phases of treatment: (1) coping with initial emotional and behavioral disruption of individual and relationship functioning following discovery or disclosure of the affair; (2) exploring individual, relationship, and outside contextual factors contributing to the initial onset or maintenance of the affair; and (3) reaching an informed decision about how to move on, either individually or as a couple. A preliminary investigation of this treatment indicated that at termination the majority of participants reported less emotional and relationship distress, and individuals whose partner had participated in the affair reported greater forgiveness toward their partner.

Research has documented the effectiveness of couple-based interventions for a broad range of individual emotional and behavioral dysfunctions. Such interventions are based, in part, on findings that couple discord predicts (a) the onset and course of psychological disorders, (b) poorer outcome to treatment of these disorders, and (c) higher relapse and recurrence of the disorders. For example, Behavioral Couple Therapy for both alcoholism and drug abuse produces more abstinence and fewer substance-related problems, happier relationships, fewer couple separations, and lower risk for divorce than does individual-based treatment. Behavioral Couple Therapy has also been shown to be effective in relieving depression when provided to distressed couples with a depressed partner. Recent findings have emerged supporting the effectiveness of couple therapy in treating patients suffering from anxiety disorders, chronic pain, cancer, terminal illnesses in general, obesity, coronary artery disease, and post-traumatic stress disorder. There also exists a broad literature regarding the reciprocal effects of couple distress and behavioral problems (especially conduct disorders)

in children and adolescents—with related parent training and family-based interventions for these difficulties.

Predictors of Couple Therapy Outcome

A substantial body of research points to a number of predictors of treatment outcome. In general, lower relationship quality, greater negative relationship affect and disengagement, and greater desired change in the relationship are all associated with poorer outcome. Similarly, lack of commitment and steps taken toward divorce have also been associated with poorer treatment outcome in some studies. Gender-role attitudes have also been studied, with findings suggesting that couples adhering to traditional roles respond less favorably to couple therapy; conversely, interpersonal sensitivity and emotional expressiveness of both partners predict better outcome at termination and long-term follow-up. Although psychological disorders (e.g., major depression, substance use, antisocial, or borderline personality) in either partner likely relate to poorer outcome, few empirical findings in this regard exist due to the exclusion of such individuals from most controlled clinical trials of couple therapy.

COUPLE THERAPY FOR SUBSTANCE ABUSE

As is widely acknowledged in the scientific and popular press, alcoholism and drug abuse are among the most deleterious and corrosive problems facing society; by virtually any standard, the personal, familial, community, social, and economic costs are staggering. Approaches to address alcoholism and drug addiction have ranged from

broad societal interventions (e.g., Prohibition, the War on Drugs) to narrowly focused biomedical treatments (e.g., use of Antabuse, which causes individuals to become ill when they consume alcohol); yet the backbone of this effort has been and remains psychosocial treatment. This entry describes the use of a particular type of psychosocial treatment, couple therapy, as an intervention for substance use disorders and includes a discussion of its theoretical underpinning, empirical support, limitations, and future directions.

Until recently, a widely touted and largely unchallenged axiom of agencies and providers who treat individuals with substance use disorders is that alcoholism and drug abuse are individual problems most appropriately treated on an individual basis. In the last quarter century, such thinking has gradually given way to a more systemic understanding of how addictive behavior evolves, is maintained, and may best be treated. This comparatively newer conceptualization has focused on how family interaction and dynamics influence substance abuse etiology, maintenance, relapse, and recovery. In turn, treatment providers have placed increased emphasis on treating the family as an approach to address a given member's or members' substance abuse.

Family-involved therapies for substance abuse can take many forms. They can focus on family issues with only one family member (e.g., the patient), they can include most or all members of the immediate family in treatment, or they may include family members from the patient's family of origin. Yet of the various family-based intervention approaches that have been developed and used by providers to treat substance abuse by adults, couple therapy has received the most attention from both the treatment and research communities. Indeed, among the various psychosocial interventions presently available to treat alcoholism and substance abuse, it could be reasonably argued that partner-involved treatments are the most broadly efficacious. More specifically, there is substantial empirical support for the use of couple-based treatments not only in terms of improvements in primary targeted outcomes, such as substance use and relationship adjustment, but also in other areas that are of clear public health significance, including intimate partner violence, children's adjustment, and cost-benefit and cost-effectiveness.

Conceptual and Practical Considerations

Theoretical Rationale

The interconnection between substance use and relationship distress appears to be marked by what can be best described as reciprocal causality. Alcoholism and drug abuse by a partner in a couple appear to contribute causally to the many relationship problems that are observed in these dyads (e.g., high levels of relationship dissatisfaction, instability, conflict, sexual dissatisfaction, psychological distress). At the same time, relationship dysfunction is strongly linked to substance use and appears to be a major contributing factor to relapse among alcoholics and drug abusers after treatment. Thus, the link between substance use and relationship problems is not unidirectional, with one consistently causing the other, but rather each can serve as a precursor to the other, creating a vicious cycle from which couples that include a partner who abuses drugs or alcohol often have difficulty escaping.

The strong interrelationship between substance use and couple interaction would suggest interventions that treat the dyadic system (versus an exclusive focus on the substance-abusing patient) hold much promise for being effective. Couple therapy approaches have two overarching objectives that evolve from a recognition of the nature and degree of interrelationship between substance use and partner interaction: (a) harness the support of the dyadic system to support positively the patient's efforts to eliminate abusive drinking and drug use and, relatedly, (b) alter dyadic and family interaction patterns to promote an environment in the home that is conducive to long-term stable abstinence. In essence, the goal of couple therapy for substance abuse is to create a virtuous cycle between substance use recovery and relationship functioning by addressing both arms of the cycle concurrently.

Elements of Couple Therapy for Substance Abuse

The couple therapy approach that has received the most extensive and consistent empirical support is Learning Sobriety Together (LST), which historically has been referred to in the empirical literature as Behavioral Couple Therapy (BCT) for alcoholism and drug abuse. For illustration, this

entry will use LST as the exemplar of couple therapy for the treatment of substance abuse.

When using LST as part of a general intervention package to treat a married or cohabiting alcoholic or drug-abusing patient, a therapist treats the substance-abusing patient with his or her intimate partner and works to build support for abstinence from within the dyadic system. The therapist, with extensive input from the partners, develops and has the partners enter into a recovery contract (which is also referred to as a sobriety contract). As part of the contract, partners agree to engage in a daily sobriety trust discussion in which the substance-abusing partner states his or her intent not to drink or use drugs that day. In turn, the patient's partner verbally expresses positive support for the patient's efforts to remain sober. For substance-abusing patients who are medically cleared and willing, daily ingestion of medications designed to support abstinence (e.g., naltrexone, Antabuse), witnessed and verbally reinforced by the patient's partner, is often a component of and occurs during the daily sobriety trust discussion. The patient's partner records performance of the sobriety trust discussion on a daily calendar provided by the therapist. As a condition of the recovery contract, both partners agree not to discuss past drinking or drug use or fears of future substance use when at home (i.e., between scheduled couple therapy sessions) during the course of couples treatment. Partners are asked to reserve such discussions for the couple therapy sessions, which can then be monitored and, if needed, mediated by the therapist. Many contracts also include specific provisions for partners' regular attendance at self-help meetings (e.g., Alcoholics Anonymous, Al-Anon), which are also marked on a calendar provided during the course of treatment.

At the start of a typical LST couple therapy session, the therapist reviews the calendar to ascertain overall compliance with different components of the contract. The calendar provides an ongoing record of progress that is rewarded verbally by the therapist at each session. It also provides a visual (and temporal) record of problems with adherence that can be addressed each week. For partners who have difficulty or otherwise are not compliant with maintaining a calendar, the therapist works with the partners at the beginning of each session constructing critical events since the previous session

and recording them on a calendar that the provider maintains and updates. When possible, the partners perform behaviors that are aspects of their recovery contract (e.g., sobriety trust discussion, consumption of abstinence-supporting medication) in each scheduled couple therapy session to highlight its importance and to allow the therapist to observe the behaviors of the partners, providing corrective feedback as needed.

Through the use of standard couple-based behavioral assignments, LST also seeks to increase positive feelings, shared activities, and constructive communication; these relationship factors are viewed as conducive to sobriety. An exercise titled "Catch Your Partner Doing Something Nice" has each of the partners notice and acknowledge one pleasing behavior performed by their partner each day. In a caring-day assignment, each partner plans ahead to surprise his or her significant other with a day when he or she does some special things to show his or her caring. Planning and engaging in mutually agreed-upon shared rewarding activities are important because many substance abusers' families have ceased engaging in shared pleasing activities; participating in such activities has been associated with positive recovery outcomes. Each activity must involve both partners, either as a couple only or with their children or other adults, and can be performed at or away from home. Teaching communication skills (e.g., paraphrasing, empathizing, and validating) can help the substance-abusing patient and his or her partner better address stressors in their relationship and in their lives as they arise, which also is viewed as reducing the risk of relapses. Relapse prevention planning occurs in the final stages of LST. At the end of weekly LST couple therapy sessions, each couple completes a continuing recovery plan. This written plan provides an overview of the couples' ongoing post-LST activities to promote stable sobriety (e.g., continuation of the daily sobriety trust discussion, attending self-help support meetings) and contingency plans if relapses occur (e.g., recontacting the therapist, reengaging in self-help support meetings).

Empirical Support

During the last 3 decades, couple therapy for substance abuse has received extensive empirical

scrutiny, with most research focusing on LST/BCT. In general, these studies have compared LST and BCT to some form of traditional individual-based treatment for substance abuse (e.g., coping skills therapy, 12-step facilitation). Findings from these studies have been consistent; compared to those who receive individual treatment, those who are randomly assigned to receive LST or BCT have (a) more time-abstinent and fewer drug- or alcohol-related problems, (b) happier relationships, and (c) a lower risk of relationship dissolution (e.g., separation, divorce).

Although not the primary targets of LST and BCT, other outcomes of clear public health significance have also favored couple therapy. Compared to individual-based treatments, participants who receive LST or BCT report significantly lower levels of intimate partner violence and improved psychological adjustment (e.g., lower levels of depression and anxiety). Recently, it has been shown that participation in LST or BCT improves the psychosocial adjustment of couples' children more than does individual-based treatment, even though children are not directly treated in either intervention. This appears to be the result of the improved family environment that comes with participation in BCT and LST (e.g., less substance use, reduced parental conflict), as well as tangible improvements in parenting behavior. Although most studies of LST and BCT for substance abuse have focused on male patients, results of more recent trials have shown that LST and BCT were more effective than other alternatives for female patients. Finally, the cost of delivering LST and BCT is comparable to that of individual-based treatments but yields significantly better clinical outcomes; as such, LST and BCT have a superior cost-benefit and cost-effectiveness profile than alternative interventions to which they have been compared.

Nearly all research to date has focused largely or exclusively on couples in which only one partner abuses alcohol or drugs; LST and BCT have been of limited effectiveness with couples in which both partners use. In addition, LST and BCT may also be less effective among couples with a substance-using partner that reports high relationship satisfaction, perhaps because relationship distress serves as a powerful motivator for change. Roughly a third of patients who would be good candidates

for BCT and LST refuse this kind of treatment, usually expressing concerns about disclosures in the presence of their partners.

Conclusions and Future Directions

Couple therapy as an intervention for alcoholism and drug abuse has made substantial strides in the last 3 decades. In particular, empirical support for its comparative effectiveness in terms of primary outcomes (substance use, relationship functioning) and secondary outcomes (partner violence, children's adjustment) is extensive. Yet despite clear evidence of efficacy, couple therapy has yet to be widely adopted in community practice. Barriers to dissemination of these approaches to community practice have been identified (e.g., limited opportunities for training in couple therapy, reimbursement problems), but research on approaches to overcome such barriers has only recently been pursued. Such research remains a critical next step to ensure dissemination of these effective approaches to those persons who may most benefit.

couples wishing to legitimize their intimate unions and for different-sex couples wishing to legitimize their unions in ways other than through contemporary legal marriage. This encyclopedia entry provides information on these options. It begins with a very brief history of heterosexual legal marriage in the United States, followed by discussions of the recently implemented coupling policies.

Legal and Common-Law Marriage

Prior to the 19th century, legal marriage was the only method by which different-sex couples could achieve legal acknowledgment of their unions. A great deal of social control was exercised over marriage (and its participants) during the Colonial Era in particular, as the Puritans believed that orderly family life was the foundation for orderly community life. Indeed, during this time, adults wishing to live alone were fined, and community members did everything they could not only to find suitable spouses for single individuals but also to exert considerable control in keeping the spouses together no matter how unhappy they were or what marital crimes (such as adultery or abuse) were committed.

During the 19th century, however, as large numbers of individuals and families traveled west to settle the frontier, many who were desirous of legal marriage found themselves unable to do so, as they settled in geographic regions far from an official (such as a justice of the peace) with the authority to consecrate such unions. As a result, couples lived together as if they were legally married, engaged in activities commonly thought (at that time) to be the purview of only the legally married (such as childbearing and childrearing), and enjoyed the social status and respect that legally married couples enjoyed from other community members. These informal arrangements were so common that 24 states officially decreed such unions as common-law marriages and accorded to these couples all of the benefits and protections associated with legal marriage.

When the West became more populated, many state governments decided that common-law marriage was no longer a practical or necessary response to the geographic barriers associated with legal marriage and subsequently revoked the legal status

COUPLING POLICIES

Over the last 25 years, numerous legal options have emerged in the United States for same-sex

of common-law unions by statute or court decision. Today, common-law marriage is increasingly becoming archaic, as only 10 states (Alabama, Colorado, Iowa, Kansas, Montana, Oklahoma, Pennsylvania, Rhode Island, South Carolina, and Texas) and the District of Columbia continue to recognize this arrangement (Georgia, Idaho, and Ohio recognize only those common-law marriages created prior to a certain date, and New Hampshire recognizes these marriages for inheritance purposes only).

For couples to be common-law married, they must live together for an ill-defined period of time (not precisely defined by any state) in one of the aforementioned states, present themselves to the public as if they are legally married, and intend to marry eventually. Both legally married and common-law married couples enjoy over 1,000 federal rights associated with marriage, as well as the corresponding rights granted to them by their respective states. Furthermore, both legally married and common-law married couples must divorce if they wish to legally dissolve their unions. It is unclear, however, how many common-law married couples divorce (or are aware that they are required to divorce) to legally dissolve their unions.

Licensed Domestic Partnerships

The first relatively new coupling policy implemented as a sort of alternative to legal marriage was licensed domestic partnerships. These partnerships were first instituted in Berkeley, California, in 1984 and were originally intended to grant public acknowledgment to the unions of same-sex couples. Local government officials at that time determined that unmarried different-sex couples also needed legal acknowledgment of their unions, particularly with regard to protecting the weaker party in the relationship upon dissolution; thus, eligibility for participation in licensed domestic partnerships was extended to them as well.

Domestic partnership ordinances typically define partners as two financially interdependent adults who live together and share an intimate bond but who are not related by blood or law. Couples wishing to license their cohabiting unions complete an affidavit attesting that they are not already biologically or legally related to each other or legally married to someone else,

that they agree to be mutually responsible for each other's welfare, and that they will notify the local government records office if there is a change in the status of the relationship (either dissolution or legal marriage). Along with a fee, the affidavit is then submitted to the local records office or in some locales, may be notarized to register the partnership. To dissolve a licensed partnership, one partner simply must inform the office where the partnership was registered. Within 6 months after this notification, an individual in most locales may then register another domestic partnership.

Since the inception of the first domestic partnership ordinance, California (in 1999), Maine and New Jersey (in 2004), Washington (in 2007), Oregon (in 2008), and the District of Columbia (in 2002) have implemented domestic partnership ordinances, as have nearly 70 municipalities (11 counties and 55 cities). Both same-sex and different-sex couples are eligible to become licensed partners in the vast majority of municipalities (three counties and five cities restrict eligibility to same-sex couples) and in all states with the exception of New Jersey (in New Jersey, both same- and different-sex couples were eligible until 2007, when civil unions were implemented for same-sex couples). Most licensed domestic partners, regardless of locale, are in same-sex unions.

Age-eligibility requirements for entering into a licensed domestic partnership differ for same-sex and different-sex couples in California, New Jersey, and Washington. Specifically, the partners in same-sex unions must both be at least 18 years of age to qualify (this is also the case in Oregon, where only same-sex couples are eligible to participate); however, different-sex unions must include at least one partner who is at least 62 years of age to qualify. These differing eligibility requirements were implemented to encourage legal marriage among different-sex couples, while also recognizing that remarrying after the death of a spouse imposes financial costs in terms of reductions in Social Security benefits to those remarrying as opposed to remaining single. In Maine and in the District of Columbia, however, partners in both same-sex and different-sex unions need be only at least 18 years of age to qualify.

The extent to which tangible benefits are granted to licensed partners varies greatly from one locale

to another. Specifically in California (in 2005) and Oregon (in 2008), essentially all state-level rights and responsibilities of marriage were extended to licensed partners. Nearly all spousal benefits were also granted to licensed partners in the District of Columbia in 2006. In Maine, New Jersey, and Washington, however, licensed partners enjoy limited benefits, which may include protection under the state's domestic violence laws, the right to inherit property from a partner without a will, making funeral and burial arrangements for a partner, entitlement to be named the partner's guardian in the event he or she becomes incapacitated, or to make decisions regarding organ or tissue donation for a deceased partner. In most counties and cities, licensed partners receive no tangible benefits whatsoever.

Finally, in a majority of locales, couples are not required to be residents in order to register as licensed partners (13 municipalities require both partners to be either residents of the city or county, or couples must include at least one partner who is an employee of the city or county). Thus, couples throughout the United States may become licensed domestic partners in many locales, although they do not reside there. Their home city or county will not acknowledge their licensed status, however, and they will receive no benefits or protections that may exist where they registered their union as a function of being licensed partners. Couples who became licensed partners in one locale and relocate to another with a domestic partnership ordinance must register in their new locale to be acknowledged as licensed partners.

Reciprocal Beneficiaries

A second current legal option, available only in Hawaii, is reciprocal beneficiaries. According to Hawaii's Reciprocal Beneficiaries Law, implemented in 1997, same-sex couples, as well as unmarried relatives and friends of heterosexual and homosexual individuals legally barred from marrying each other, are eligible to register with the Hawaii Department of Health as reciprocal beneficiaries (although only two individuals may form a registered reciprocal beneficiaries union, extending eligibility to those individuals not in an intimate union makes Hawaii's policy

unique, and not a coupling policy like the others described in this entry). There is no state residency requirement; indeed, registrants are not required to be U.S. citizens. The law grants some of the benefits of marriage to reciprocal beneficiaries, including property rights, protection under the state's domestic violence laws, the ability to visit a beneficiary in the hospital and to make medical decisions for him or her, to sue for the wrongful death of a beneficiary, and to inherit property without a will. Because individuals in reciprocal beneficiaries are legally single, dissolving the relationship legally simply involves informing the Hawaii Department of Health of its termination.

Civil Unions

Vermont (in 2000), Connecticut (in 2005), New Jersey (in 2007), and New Hampshire (in 2008) have implemented civil unions legislation, a legal option available only to same-sex couples. With the exception of sexual orientation, couples must meet the eligibility requirements for legal marriage in their state to register their unions. At the state level, civil unions are the functional equivalent of legal marriage in that they provide to couples all of the benefits and protections of marriage afforded to spouses. Due to the federal Defense of Marriage Act signed into law by President Bill Clinton in 1996, however, which defines marriage as consisting of the legal union of one man and one woman, these couples do not enjoy at the federal level any of the benefits or protections afforded to the legally married. Furthermore, although nonresidents are eligible to form civil unions in these four states, only in New Jersey do couples in civil unions formed in other states receive any state-level legal acknowledgment, benefits, or protections associated with their unions (Vermont, Connecticut, and New Hampshire do not grant legal acknowledgment to civil unions contracted elsewhere, nor does any state without civil unions legislation).

Legally dissolving a civil union in one of these four states involves the same process as dissolving a marriage in that state in that one partner must file for divorce (and meet the eligibility requirements for filing). If a couple that entered into a

civil union either relocates to or are residents of another state, however, and they wish to legally dissolve their union, the lack of acknowledgment of civil unions in other states makes obtaining a legal divorce difficult if not impossible. The granting of a divorce appears to occur on an ad hoc basis.

Same-Sex Marriage

Another legal option is same-sex marriage. Currently, Massachusetts (since 2004) is the only state in the United States that permits same-sex couples to legally marry (same-sex marriage was legalized in the Netherlands in 2001, Belgium in 2003, Canada and Spain in 2005, and South Africa in 2006). The national Defense of Marriage Act, however, dictates that states are not required to legally recognize the same-sex marriages contracted in any other state. Currently, California recognizes same-sex marriages legally contracted elsewhere, whereas New Jersey translates these marriages into civil unions if couples relocate there. Both states provide to these couples all of the state-level benefits and protections of legal marriage.

Similar to civil unions, same-sex marriage in Massachusetts and California grants to couples all of the benefits and protections afforded to the legally married at the state level, but these couples do not enjoy any of the benefits or protections afforded to the legally married at the federal level as a result of the Defense of Marriage Act. Furthermore, because few other states currently legally acknowledge the same-sex marriages contracted in Massachusetts or California, couples may be prohibited from divorcing if they relocate to another state.

Covenant Marriage

Coupling policies in the United States have also taken a conservative direction in some states. In Louisiana (in 1997), Arizona (in 1998), and Arkansas (in 2001), different-sex couples only have the option of choosing either a covenant marriage or a contemporary marriage. A covenant marriage is a return to traditional marriage reminiscent of those prior to the 1970s and the

advent of no-fault divorce. In a covenant marriage, couples are required to undergo premarital therapy, the purpose of which is for partners to make clear to each other their expectations for marriage and to resolve any problems before the couple enters into the marriage. Furthermore, couples in a covenant marriage may only divorce under extreme circumstances, such as adultery, physical abuse, and long-term imprisonment or abandonment. A contemporary marriage does not require premarital therapy, and couples may divorce under no-fault grounds that are available in all states, such as irreconcilable differences. Couples in Louisiana, Arizona, and Arkansas who legally married prior to the implementation of covenant marriage have the legal option of converting their marriages to covenant marriages, and indeed, most couples in covenant marriages are those who were married prior to the legislation's implementation. Legislators in an additional 20 states have considered implementing covenant marriages, though to date, no other states have done so.

In sum, most of the recent coupling policies in the United States reflect the country's growing acknowledgment of intimate relationships that differ from the historical model of heterosexual legal marriage. Although covenant marriages are an exception to this trend, the momentum is clearly in a progressive and inclusive direction. Indeed, the rapid increase in the number of states implementing licensed domestic partnerships and civil unions, as compared to the much slower growth in the number of states implementing covenant marriages, further indicates that the United States is taking a more progressive stance with regard to intimate unions.

In terms of how the U.S. policies compare to those in other parts of the world, however, the United States continues to be a moderate model. Although space limitations prohibit a full discussion of coupling policies in other countries, a few comments are in order. Most importantly, Western industrialized nations vary greatly in the extent to which their coupling policies are inclusive. Coupling policies in Scandinavian countries, for example, provide a great number of benefits and protections to the couples who participate in nonmarital unions; indeed, in some cases, licensed cohabitators are virtually

indistinguishable from the legally married in this respect. In other countries, especially those that are Catholic (such as Ireland and Italy), policies continue to focus on marriage to the virtual exclusion of other types of families (families headed by single parents are increasingly receiving attention in Irish policies, though couples cohabiting outside of marriage, at the time of this writing, continue to be largely ignored). There does appear to be a sort of meeting in the middle, however, with regard to coupling policies. Conservative countries are slowly but surely implementing more inclusive policies, while policymakers in progressive countries are increasingly questioning whether their policies of inclusivity can be economically maintained.

COURTSHIP, MODELS AND PROCESSES OF

Courtship can best be defined by its overall objective and the behaviors that characterize this period in human relationships. Traditionally, the objective of courtship is to develop a relationship that leads to marriage. As societal customs and practices change, however, the more accurate objective of courtship may be to develop a relationship that leads to a long-term commitment—marriage, cohabitation, same-sex union. Courtship behaviors include dating and other activities that provide couples with information that can lead to such a long-term commitment. It is important to understand courtship because the nature and quality of courtship can influence the quality of later marriage and other committed unions. Relationship scientists have offered courtship models that specify a series of time-ordered stages that lead to marriage or committed relationships. More recently, the focus has changed from stage models to a perspective that acknowledges the various pathways that people take to marriage or commitment. This entry discusses the models of courtship that have been developed by relationship theorists and researchers. The discussion focuses on elements of each model and any shortcomings that may exist.

Models of Courtship

In early America, the method of choosing a mate was fairly straightforward. Choice of a partner was based on relatively rational factors: whether the man had sufficient resources to support a wife, whether they were of similar social status, and whether their parents approved of the potential marital partner. These factors were likely somewhat easy for potential partners to determine, but there is little doubt that deception was common between courting pairs. Over time, these rational factors became less important in choosing a mate; while at present, in the Western world, relatively intangible factors are more important in this choice. People seek relationships that promote love between partners, compatibility, and the potential to make each other happy. These less

tangible factors are not as easily determined by a courting couple. Consequently, relationship scientists have proposed several models of how relationships move to marriage. The following sections discuss these models.

Compatibility Models

The first formal models of courtship assumed that individuals search for potential partners on the basis of compatibility, that is, how similar or different two potential partners are to each other. One of the earliest models of courtship was the complementary needs model, which embodies the idea that opposites attract. The complementary needs model suggests that individuals have needs that must be met, and therefore, people seek partners that are able to fulfill these needs. For example, if Jack has a need to be dominant in a relationship, the ideal partner, Jill, would have a low need for dominance so that Jack is able to be the dominant partner in the relationship. The perception that one's partner complements one's needs leads to development of the courtship.

In contrast to the complementary needs model, the similarity model suggests that potential mates are attracted to each other because they are more alike than different in social characteristics, values, and attitudes. This model represents the popular notion that birds of a feather flock together. According to this model, ideal partners are those who are similar on traits such as religion, age, ethnicity, values, and so on. For example, if Jack is a 20-year-old White Catholic, he would be more likely to choose Jill, a 20-year-old White Catholic, than Ann, a 35-year-old African-American Muslim. According to this model, similarity fosters compatibility because (a) individuals enjoy having things in common with others, (b) interacting with similar people validates the traits that provide individuals with feelings of self worth, or (c) they anticipate less conflict over differences in the future. Consequently, the perception of similarity is seen to stimulate the progression to marriage.

Both the complementary needs and similarity models have shortcomings that limit their usefulness. The primary shortcoming of the complementary needs model is that there is little research to

support it. The similarity model has received more support, but there are alternative explanations for the development of similarity that limit the ability of the model to explain how individuals initially select each other. Social structure (e.g., social class) tends to group similar people together in neighborhoods, schools, and other physical settings. Consequently, the likelihood of meeting dissimilar people is relatively low. In addition, partners tend to grow more similar to each other over time, a tendency which suggests that partners do not necessarily select each other based upon similarity.

Stage Models

Stage models of courtship propose that mate selection involves a series of steps or stages. These models build on the compatibility models by combining the ideas of complementarity and similarity, as well as other factors. Several stage models of courtship have been proposed including filter theory, Stimulus-Value-Role (SVR) Theory, and premarital dyadic formation framework.

Social scientists Alan Kerckhoff and Keith Davis proposed a filter theory of courtship that combined the notions of similarity and complementarity. According to filter theory, people first seek partners with similar social characteristics, such as age, religion, and education, as well as people who are similar in values and attitudes. After dissimilar others are filtered out, individuals look for those who complement their needs. At this point, commitment is solidified.

Social scientist Bernard Murstein proposed the Stimulus-Value-Role (SVR) Theory of courtship, an extension of the filter theory. This theory argues that courtship develops through three stages. In the stimulus stage, individuals consider partners who are similar on a number of characteristics. The primary stimulus for screening potential partners is physical attractiveness, although other characteristics such as behavior or reputation are also considered. After narrowing the field of potential partners based on stimulus factors, individuals begin screening on the basis of values. In the value stage, individuals evaluate similarity of values including attitudes, beliefs, and needs. This comparison begins with increased communication

and self-disclosure about general topics but may move into more personal topics such as religion, politics, and so on. As individuals become aware of potential similarity in values, they move to the final role stage. During the role stage, partners attempt to determine the compatibility of the specific roles that each will play in the continued relationship. This determination helps partners to understand the expectations that they have for one another regarding their future. For example, such roles may include primary wage earner, friend, decision maker, and so on. Successful completion of all three stages was originally thought to prepare couples for marriage.

Social scientist Robert Lewis proposed the premarital dyadic formation framework, which suggests that relationship formation is based upon a series of six processes, which are all completed before a partner is selected. During the first process, perceiving similarities, individuals identify potential partners who are similar to themselves in terms of background, personality, interests, and values through interaction and observation. The second process, achieving pair rapport, follows from perceived similarity. During this process, partners familiarize themselves with each other and engage in open communication, which leads to the third process, inducing self-disclosure. By achieving rapport with each other, partners begin to disclose personal information, which allows partners to begin the fourth process, role taking. During the role-taking process, partners begin to include each other in their relationship roles. In the fifth process, achieving interpersonal role fit, partners determine how well they fit together based upon their personality similarity and role complementarity. The last process, achieving dyadic crystallization, occurs when the previous five processes have been accomplished. During this process, partners begin to establish patterns of interaction and relationship goals.

Although the stage models are built upon the compatibility models, they still have several limitations. The stage models suggest that relationships consistently develop from a series of sequential stages. It is not always clear, however, why the stages occur in the given order. For example, in SVR Theory, it is not clear why the value comparison stage comes before the role comparison stage. In addition, these models

assume that relationships begin with considerable communication of feelings. Research has shown, however, that many relationships proceed with limited intimacy or disclosure. Further, the stage models do not represent the complexity of the courtship process. These models suggest that all couples move similarly through the stages and that compatibility is the primary force that facilitates relationship development, which ignores other potential influences on the courtship process.

Social Exchange Model

According to the social exchange model, relationships develop through an exchange of desired rewards between partners. In developing relationships, each individual considers the rewards (i.e., positive experiences) and costs (i.e., negative experiences) of being in the relationship. If they are receiving more profit (rewards minus costs) in the present relationship than they generally have in the past from other partners, they will be satisfied, thus setting the stage for a deeper commitment. However, the social exchange model proposes one additional factor that determines whether the relationship will actually move toward marriage. Relationships will move to deeper levels of commitment when the partners perceive that the satisfaction with the current partner exceeds the satisfaction that they could receive from any other potential partner.

The social exchange model also has a number of shortcomings. The social exchange model is based upon the calculation of rewards and costs. However, these calculations may not be easy for people to assess and to keep track of. Further, this model portrays people as self-serving because it suggests that individuals are only interested in obtaining the most rewarding relationships rather than also considering the well-being of the partner. As such, this model does not explain why partners may be responsive to each others' needs.

Evolutionary Model

The evolutionary model proposes that processes have evolved over historical time to influence the process of finding and keeping a mate. According to early theorists, humans have evolved certain preferences and strategies that

maximize the likelihood that they will successfully reproduce and pass on their genes. Due to successful reproduction over long periods of time, these preferences and strategies evolved as general tendencies in humans. In general, men evolved a tendency to prefer and mate with physically attractive (e.g., healthy) women because in ancient times healthy women were more likely to bear children. On the other hand, women evolved a preference for men with sufficient resources to support and sustain children because ancestral women who mated with such men were more reproductively successful. More recent theorizing and research, however, has shown that the use of these preferences and strategies depends on whether individuals are seeking a short-term or long-term relationship.

When people seek a short-term partner, both men and women place a relatively higher value on physical attractiveness. According to the evolutionary model, this emphasis is beneficial to men because the more women they mate with, the more likely they are to reproduce. Women may benefit from an attractive partner in short-term pairings because it might increase the likelihood of finding a genetically superior mate.

More pertinent to courtship, evolutionary theorists suggest that preferences will differ between men and women when people seek long-term mates. In addition to seeking reproductively fit women, men will also seek women who will be sexually faithful, thus ensuring that any offspring will possess their own genetic heritage. Women seeking long-term partners will prefer men who are willing to invest their resources in them and their children, as well as providing them with protection.

In order to attract and keep a suitable long-term partner, evolutionary theorists suggest that people will employ certain tactics to maximize the stability of those relationships. For example, women seeking a long-term relationship may communicate their willingness to be sexually faithful because they know men seeking long-term relationships desire that in a partner. Alternatively, a woman may communicate that other available women are promiscuous and not suitable for a man who wants a long-term relationship. A man seeking a long-term partner, however, may talk to a desired partner about the likelihood that his resources will greatly increase over time, thus suggesting his

ability to provide for a partner and children in the long run. Alternatively, he may talk about rivals being unwilling to commit to a long-term relationship. When such tactics are successful, the likelihood that the relationship will move closer to marriage or to a deeper commitment is enhanced.

The evolutionary model also has several weaknesses. This model suggests that courtship processes reflect behaviors that have evolved over long periods of time. Therefore, it is very difficult for scientists to accurately determine whether or not the relationship patterns that exist currently are due to evolution or to some other influence. Further, although the model assumes that current traits have evolved because they were successful in the evolutionary past, the role of these traits does not always translate effectively into the current environment.

Interpersonal Process Model

As discussed previously, stage models of courtship have not been widely accepted by social and relationship scientists. They suffered from a lack of empirical research and were conceptually weak. In addition, stage models portrayed courtship as a relatively simple progression to commitment because they postulated that only a few factors were influential. More recently, relationship scientists have suggested that courtship is more complex and involves several factors in the course to commitment. This perspective has been termed the interpersonal process model.

Proponents of the interpersonal process model of courtship assume that the movement to commitment or marriage is the result of the unique interaction of couples. They propose, however, that this unique interaction is influenced by the individual characteristics of partners (e.g., sex, personality, temperament, attitudes), the characteristics of their relationship (e.g., compatibility, similarity in attitudes and values), social context (e.g., social class, social network), and the physical context. These multiple factors can act individually or together to influence the pathway to commitment. Relationship researchers believe these multiple influences lead to different paths to marriage. In order to illustrate the interpersonal process model, a discussion of empirical research from this perspective follows.

Rodney Cate, Catherine Surra, and Ted Huston began a series of courtship studies from an

interpersonal process perspective in the late 1970s. Their first studies were conducted with newlywed couples that were interviewed and asked to complete questionnaires about their courtships. The interviews focused on courtship turning points where partners became more or less committed and the reasons for these changes. The questionnaires asked about behaviors, feelings, and beliefs that characterized their relationship at various points in the courtship. Analyses of the couples' responses to the interview and questionnaires revealed a picture of courtship that was more complex than was suggested by earlier compatibility and stage models. Some courtships were quite prolonged, with lots of upturns and downturns during the path to marriage. Other courtships accelerated quickly to high levels of commitment, while others took a moderate course to high levels of commitment.

Several factors distinguished these different pathways to marriage. People in prolonged courtships reported more conflict and ambivalence (i.e., indicators of incompatibility) about staying in the relationship than those in the accelerated and moderate courtships. The turbulent nature of prolonged courtships seems at odds with earlier models that viewed courtship as an orderly progression to marriage that focuses on assessing compatibility between partners. Moderate courtships, however, seemed to resemble the pathways suggested by compatibility models. Those in moderate courtships had less conflict and ambivalence about the relationship than those in other types. Additionally, factors not related to compatibility were associated with having a moderate courtship. For example, those in moderate courtships tended to be older at the time of meeting their partners. This suggests (but does not prove) that those in moderate courtships may feel some outside pressure to marry because of their age.

Factors external to the relationship may also play a role in accelerated courtships. Those in accelerated courtships reported more parental approval of their partner than those in other types of courtship, suggesting that parental approval may play a more important role in the course to marriage. Unfortunately, a 2-year follow-up of these couples was unable to locate enough of them to see how those in different types of courtships fared during marriage. For the couples who were contacted, those who reported high conflict during

the premarital period were more likely to be experiencing higher conflict 2 years after they married. In addition, one might expect that those in accelerated relationships would be more prone to marital failure because short courtships are predictive of fragile marriages, but that has not been confirmed. Overall, this research supports the value of examining the many factors that play a role in understanding the path to commitment and marriage.

Conclusions

The nature of courtship has evolved from a relatively straightforward and formal process in the 1800s to the relatively complex process of today. Different models and processes of courtship will be identified as relationship scientists respond to contemporary changes in society. Future models will have to address how societal changes affect the processes of courtship. There is little doubt that the current increase in nonmarital cohabitation and Internet-based methods of meeting potential partners will become increasingly important in the courtship process. Other changes are sure to come.

COURTSHIP AND DATING, CROSS-CULTURAL DIFFERENCES IN

Couple formation is a fascinating process that ensures the continuation of human societies. Although there are many similarities in how individuals are paired with another, there are also many variations on how partners might come together to form a pair bond. Despite variations, courtship and dating play an important role in the creation of romantic partnerships and marriages. This entry begins by introducing two helpful theoretical frameworks for examining couple formation. It then discusses dimensions of difference in selection practice and factors that influence the experience of courtship. Specific contemporary cultural practices are interwoven throughout to provide a glimpse into the variety of courtship and dating experiences.

Theoretical Frameworks

Social exchange theory offers a rich framework for examining the initiation and development of pair relationships. It suggests that pair bonds occur within a social marketplace so that people are most attracted to and attempt to pursue relationships with those who are able to maximize their rewards (e.g., attractiveness, wealth, status, love) and minimize their costs (e.g., insecurity, inequality, exploitation, lack of social approval). As rational beings motivated by self-interest,

humans will make choices that yield the most personal profit, yet they recognize that their partner needs to also find the relationship profitable in order to remain committed to it.

Using this marketplace perspective, the main differences between cultures lie in who conducts the negotiations for marriage, how explicit the bargaining is, and what criteria or currency of exchange are employed. Regardless of mate selection systems, criteria always exist for evaluating which potential mates are deemed more or less desirable. There can be surprising continuity across cultures in the attributes most desired in a mate. Bibiana Minervini and Francis McAndrew discovered that mail order brides (MOBs) from Colombia, Russia, and the Philippines, regardless of culture, were searching for the qualities of commitment, ambition, and sexual fidelity in prospective husbands. When cultural differences in criteria are observed, they often relate to the degree of autonomy in mate choice. In general, arranged marriages place higher priority on criteria linked to family background, reputation, and lineage, while free choice marriages focus more on personal criteria such as interpersonal attraction, personality, and romantic love.

Filter theory offers another useful framework to better understand how people sort through a pool of eligibles for potential mates. Consciously or unconsciously, people sift possible mates through a series of screens to narrow down the field. First, propinquity or geographical proximity impacts with whom people are most likely to come into contact. Despite the increasing use of the Internet to meet partners, physical distance makes relationships more challenging, so people are more likely to pair with people who live, work, or interact in the same region that they do. The social background filter enforces homogamy, suggesting that those who are similar in education level, religious beliefs, socioeconomic status, age, racial and ethnic heritage, and values and beliefs are more desirable partners. Endogamous expectations may dictate that a Muslim marry another Muslim, for instance. Cultural norms also prescribe who should be excluded from the pool. Kenyans typically eliminate those who practice witchcraft from consideration. Exogamy, the requirement to marry outside a certain group, would also apply. In some cultures, for instance, people are prohibited from marrying

close relatives. Physical attractiveness may provide another filter, reflecting culturally socialized standards of beauty. The final screens are need complementarity or compatible personality and the balance sheet filter that determines equity in exchanges within the relationship. If mutuality and reciprocity exists, commitment is likely.

Dimensions of Cultural Difference in Mate Selection

Courtship and dating practices vary enormously from one world culture to the next. Some are subtle and understated, while others are exotic and flamboyant. One approach to account for such a baffling and seemingly unpredictable array of mate selection practices might be to identify dimensions of cultural difference often linked with particular courtship traditions and rituals.

Arranged Versus Free Choice Marriage

All societies fall somewhere along a continuum from purely arranged to purely autonomous marriage. In many cultures, matchmakers continue to be employed in bringing pairs together. A friend, family member or professional could serve as a go-between by researching family backgrounds, social standing, temperament, and appearance of marriageable partners; organizing their meeting; and even negotiating their marital contract. Historically in Japan, a *nakado* often facilitated the identification of a suitable partner and served as an advisor for wedding preparations and after marriage, though they are used infrequently today. Similarly, arranged marriage has been the norm in India for many centuries. More recently, matrimonial advertisements and Internet dating services have increased the involvement of young people in marriage partner selection, though in many cases parents still initiate the advertisements and supervise the prescreening of prospective mates.

Internet dating services represent a type of contemporary matchmaker while also allowing personal choice. Individuals are able to filter through potential partners by identifying criteria important to them. So despite being introduced to a multitude of potential partners, the individual makes choices about who to engage or meet. Free choice

relationships are frequently based on the notion that marriage should be a matter of personal happiness and based on mutual affection. China's revised Marriage Law of 1980 reframed marriage as a personal decision rather than as a matter of extended family stability.

Comparative Age at First Marriage

The age at first marriage can also vary widely depending on whether a culture practices child marriage and early union or whether late marriage has become the norm. Although some states in the United States still permit marriage as young as 14 with parental consent, early marriage is most commonly practiced in sub-Saharan Africa and South Asia. For example, 5 percent of all children in Bangladesh between the ages of 10 and 14 are married, and 50 percent of all Amhara girls in Ethiopia are married by age 15. By contrast, the trend in the United States over the past 40 years has been to delay marriage. Indeed, late marriage has become the norm in many Western European countries such as Sweden, where the median age at first marriage is 32 for women and 35 for men.

Perceived Economic Value of Women

Courtship practices are also influenced by the extent to which a society views women as economic assets or liabilities. In East Africa, where women are valued for their significant contributions to micro-enterprise and agrarian economies, a groom's family often pays bride-price to compensate the bride's family for the loss of her economic contribution. This practice, known as *lobola* in South Africa, was traditionally paid in cattle. Even a person of such international stature as President Nelson Mandela followed this time-honored tradition by paying his wife's family 60 cows for her hand in marriage in 1998. Conversely, in societies that traditionally view women as a drain on family resources, the bride's family may need to pay dowry to the groom's for agreeing to assume the economic obligations of feeding and clothing the new bride.

Degree of Economic and Societal Complexity

It has been observed that mate selection systems mirror in part the economic transformations of a

society. Preindustrial societies with agrarian-based economies are often more conducive to arranged marriage due to the tendency for extended kinship groups to live and work together on land that may be passed from one generation to the next. The worldwide shift toward industrialization, urbanization, and modernity has created economic systems that thrive on a labor force with greater mobility, flexibility, and independence of thought. Themes of individualism required for both industrialized economies and free choice mate-selection systems tend to mutually reinforce each other.

Degree of External Monitoring

There is also wide divergence among world cultures in the degree of social control brought to bear on the courtship process. In traditional societies, romantic love was often viewed as a tragedy due to its potential to wreak havoc with societal structures and class or caste systems. Strategies that channel romantic impulses of the young have been described as structural constraints of romantic love. The most controlling of these may be child marriage, where a mate is selected before a child is old enough to form an opinion on the matter.

Other practices along the continuum include strict separation of the sexes, strict limits on the pool of eligibles, chaperonage, and indirect parental control. An example of chaperonage is seen in the kitchen table dates practiced by Cuban immigrant families in suburban New Jersey as a means of monitoring potential suitors of their daughters. In this case, courting couples were not permitted to leave the house on an unaccompanied date but were encouraged to cultivate their friendship around the family kitchen table under the watchful eye of family members.

Degree of Separation From Intent to Marry

There are clear cross-cultural differences in the symbolic meaning and significance attached to courtship rituals. With the advent of steady dating during the 1930s and 1940s in the United States, courtship came to be viewed as recreation in its own right. Unlike earlier centuries where Americans primarily dated those they perceived as viable marriage prospects, steady dating came to be separated from the intent to marry. In many American high

schools, it was more important to be going steady with someone than to be dating a person one might actually consider marrying. The opposite is true in many traditional societies across the world today. In some West African cultures, for example, one only begins to date publicly those individuals considered to be a serious prospect for marriage.

Degree of Commercialization

Yet another area of cross-cultural difference is the extent to which the locus for courtship is the more intimate sphere of family and community, versus the public sphere of commercialized entertainment and leisure. In traditional Amish society, couples pursue their courtship in such venues as Sunday-night singings, family weddings, and community softball or volleyball games.

By way of contrast, the past century has seen a tilt in mainstream American culture toward the commodification and commercialization of courtship. Daniel Cere estimated that during the 2 and a half years of a typical courtship, it is not uncommon for one to pay upward of \$40,000 on restaurant tabs, flowers, movies, concerts, jewelry, trips, gifts, and wedding expenses. The recent widespread use of Internet dating services can add a \$20 to \$50 per month to the cost of securing a serious marriage prospect.

Relative Role of Nonmarital Cohabitation

Because cohabitation has come to be so widely practiced in Western countries, it is important to consider what connection, if any, cohabitation has to traditional notions of courtship and dating. Indeed, 70 percent of all individuals marrying in the United States today have cohabited at some point prior to their marriage, though not necessarily with their spouse. It is generally recognized that for some, cohabitation is an extension of going steady. It is prompted by a desire for friendship and intimacy with a person one may or may not consider to be a viable candidate for marriage. Over half of cohabiting couples eventually do go their separate ways. In other instances, cohabitation clearly functions as a trial marriage, an opportunity to test out or simulate marriage to one's nonmarital partner.

In addition to viewing cohabitation as a courtship ritual or a trial marriage, it can also function as a permanent alternative to legal marriage. This

is most prevalent in countries where legal marriage is beyond the economic reach of many young people. In Jamaica, where only 16 percent of women are legally married during their childbearing years, courtship rituals often evolve into long-term visiting unions for women and the fathers of their children. Cohabitation as a permanent alternative to marriage is also seen in countries like the Netherlands where social mores are more accepting or the United States where access to welfare and government support programs is severely restricted for households headed by two legally married individuals. Clearly, in other contexts cohabitation is frowned upon, as is evident in Eastern Indonesia where a derogatory term, *kumpul kebo*, is used to identify such couples. In Trinidad, those shacking up also receive social disapproval. Similarly, societies that place a premium on chastity before marriage would also object. In countries like Morocco and Algeria, a young woman may be required to undergo a medical examination to secure a virginity certificate verifying her acceptability for marriage.

Thus, courtship practices are impacted by cultural differences relative to the desirability of matchmaker involvement, age at first marriage, the economic value of women, the degree of economic and societal complexity, the level of external monitoring, the salience of courtship on the intent to marry, the amount of commercialization, and the level of normativity of nonmarital cohabitation.

COVENANT MARRIAGE

Can the government reduce marrying couples' chances of divorce with a law or policy? The designers of covenant marriage think so. This entry explains the history of covenant marriage and its implementation, describes the first couples to marry under the law, and finally answers whether covenant marriage does, in fact, reduce divorce. Covenant marriage is a law first passed in August 1997 in Louisiana. This legal innovation marked the first time in U.S. history that heterosexual marrying couples could choose between two sets of laws to govern the terms of their marriage. Katherine Shaw Spaht, the Jules F. and Frances L. Landry Professor of Law at Louisiana State University, and then-freshman legislator Tony Perkins drafted and introduced the covenant marriage bill. Spaht writes extensively about the legal implications and social benefits of covenant marriage. Perkins served two terms in the Louisiana state legislature and is a strong proponent of covenant marriage. As of this writing, he now serves as president of the Washington, D.C.-based Family Research Council.

As part of rising public concern about the stability of the American family, covenant marriage grew directly out of U.S. state and federal debates about welfare reform, marriage and healthy relationship promotion, and Defense of Marriage Acts. The majority of state legislatures have considered versions of covenant marriage bills, but only three states have currently enacted this option: Louisiana, Arkansas, and Arizona. Many states have implemented features of the covenant marriage law by enacting forms of premarital counseling requirements and expanding state-sponsored opportunities for marital and relationship counseling.

The intended policy-relevant purposes of covenant marriage are largely threefold. First and foremost, covenant marriage's primary legal purpose is to improve marital stability and reduce divorce. Second, covenant marriage's more controversial social purpose is to act as a beacon against the presumed ill effects of a culture that weakens norms about the traditional meaning of marriage and encourages divorce as a permissible easy out. Third, covenant marriage serves a symbolic

purpose by allowing covenant marrying spouses to signal to each other their trust in the permanence of their union and to their children that they too will find reliable, faithful spouses for lifetime permanent marriage. Research clearly documents that couples find great meaning in the public and private symbolic purposes of covenant marriage.

The covenant marriage laws themselves stand as a retrenchment against no-fault divorce laws. Covenant marriage provisions require that couples undergo premarital counseling by a state-approved counselor or religious officiator, sign a notarized affidavit that they have disclosed their personal and sexual histories fully to each other, and submit a declaration of intent acknowledging that covenant marriage is a lifetime permanent relationship. The divorce provisions in the Louisiana covenant marriage law are fault based. A divorce may be granted for the traditional marital faults of infidelity, physical or sexual abuse of a spouse or child, abandonment of at least 1 year, or a lifetime or death-penalty conviction. Covenant marriage does not permit unilateral divorce nor consider general incompatibility as a criterion for termination. Covenant couples who want to divorce must undertake required marital counseling. In Louisiana, the waiting period for divorce is 2 years for a covenant as compared to 6 months for a standard marriage. There is some confusion about whether covenant married couples who prove fault must undertake marital counseling. For instance, some interpret the law to mean that even couples in violent relationships must make good faith efforts at counseling to preserve their marriage, while some judges grant instant divorces, with waiting periods even shorter than for standard marriages.

Most empirical research about covenant marriage comes from a series of multimethod studies funded by the National Science Foundation and a private foundation and led by Steven L. Nock and his co-investigators, Laura Sanchez and James D. Wright. Their research included evaluation studies of the implementation of the law and its counseling facets; focus group interviews with people with a political or personal stake in covenant marriage, such as feminist organization members who opposed covenant marriage; long-married couples who upgraded to covenant marriage; and special targets of the law, such as young unmarried people and welfare-dependent single mothers. Their research

also included an attitude survey of the general population and a three-wave, 7-year survey of approximately 700 covenant and standard married couples who married shortly after the passage of the covenant marriage law, accompanied by qualitative interviews between the second and final wave.

In covenant marriage's first year, evaluation studies demonstrated that the law was implemented poorly. Clerks of the court and court staff routinely did not inform couples applying for licenses about the option and reported that they did not support covenant marriage. Often religious officiators or counselors, especially Catholic priests, did not counsel couples about covenant marriage because they did not approve of a state law that made two forms of marriage to support a singular vision of permanent marriage nor that required them to counsel couples about divorce provisions. Among the general public, very few people had heard about the covenant marriage law.

For this and other reasons, only about 2 percent of newly contracted marriages were covenant marriages within the first 2 years of the law's passage. Accurate information about the number of already married couples who upgraded their standard marriages to covenant marriages is nonexistent. More recent information about the percent of all new marriages that are covenant marriages is also nonexistent. However, occasionally, evangelical mega churches or other covenant marriage-supporting organizations host mass upgrade ceremonies, often on Valentine's Day. For example, Governor Mike Huckabee of Arkansas upgraded his 31-year marriage to a covenant marriage in a mass ceremony at a Little Rock sports arena on February 14, 2005.

Nock, Sanchez, and Wright's study finds that covenant couples differ from standard couples in significant ways. Covenant couples are 4 times more likely to have first met in church than standard couples, and their weddings are more religious, more traditional, and attended by many more guests. Compared with covenant couples, standard couples and spouses are much more likely to have ever cohabited and to have a child together or children from previous relationships at the start of their marriages. Covenant couples hold more traditional gender role attitudes and share greater spousal agreement about these roles. In contrast, standard couples are often mismatched with husbands almost as traditional as covenant

husbands and wives are considerably more liberal. Covenant couples report less corrosive and negative marital communication and conflict resolution strategies than standard couples.

By far, religiosity marks the biggest gap between covenant and standard married couples. Across numerous measures, covenant couples are much more religious, and the spouses are in close agreement about the centrality of religiosity and mutual participation. They are also much more likely to be evangelical. On average, standard couples are less religious and have a much broader range of religious experience across and within couples. Covenant couples are very likely to perceive God as an active directing presence in marriage and the Devil as a force working to destroy American families.

Covenant and standard married couples share some critical similarities. They have similar levels of education, occupation, and earnings. Husbands and wives in both forms of marriage engage in paid employment and housework in similarly gendered ways.

Nock, Sanchez, and Wright found that covenant married couples have significantly lower chances of separation and divorce than standard married couples (8.6 percent vs. 15.4 percent respectively, by the end of their study), at least within the first 7 years of marriage. But these lower chances of divorce were tied wholly to the selection effect of their greater religiosity, particularly covenant wives' greater religiosity. In essence, although more religious couples were more likely to choose covenant marriage, they were less likely to actually need it. Their greater religiosity was the acting buffer against divorce, not their choice of covenant over standard marriage. Their research also shows that intensive premarital counseling reduces divorce, a noteworthy finding for policymakers since 99 percent of covenant versus 42 percent of standard marrying couples underwent premarital counseling. However, a perplexing finding was that, for both covenant and standard married couples, counseling during marriage was associated with substantially higher chances of divorce. They conclude that marriage promotion and healthy relationship initiatives and family researchers must study the mechanisms behind postmarital counseling and greater chances of divorce.

CRITICISM IN RELATIONSHIPS

Criticism is a verbal statement negatively evaluating another person. In close relationships, topics of evaluation typically include personal characteristics, behavior, performance or skills, physical appearance, relationship-related issues, and decision making. As an interpersonal activity, criticism is closely related to expressing complaints and giving feedback. Complaining, a more general interpersonal behavior, may or may not be about the complaint recipient. Complaints that are directed toward the relational partner specifically as the source of personal dissatisfaction are criticisms. For example, expressing dissatisfaction with the weather is a type of complaint that is not a criticism. Complaining to someone that he or she is always late is a complaint that also is a criticism. Criticism is not necessarily a complaint, however, and can be expressed as a relatively objective observation rather than a personal irritation. Telling a friend that shoes do not go with an outfit is a criticism that is not a complaint.

Feedback, on the other hand, refers to criticism focused on performance or skill, typically given in the context of instructional or professional relationships. This entry examines the communication of criticism, factors influencing decisions to express or suppress criticism, and the consequences of criticism for individuals and relationships.

Communicating Criticism

Giving Criticism

Criticism is a speech act that can be useful but difficult to hear. How criticism is communicated affects whether or not it is perceived to be constructive or destructive. In general, recipients respond more positively to criticism that is specific, clear, and communicated in conjunction with positive evaluations (e.g., “When we make dinner plans, you are frequently late; I love having the chance to see you, but would enjoy it more if you show up at the time we agree on”) than criticism that is negative, general, and vague (e.g., “It irritates me that you are always showing up late”). Nonverbally, constructive criticism is communicated with calm, positive nonverbal affect in contrast to loud and/or hostile nonverbal cues. Additionally, criticism communicated in private tends to get a better response from the recipient than public evaluation. The content of criticism also matters. Recipients are more likely to respond positively to criticism that they perceive to be accurate and fair, that contains suggestions for action, and that reflects concern for the individual.

Although criticism has an instrumental purpose (i.e., encouraging change or personal development), effectively communicating criticism also requires attention to what it says about the individual and the relationship. Criticism can be a face-threatening activity that undermines the desired social identity of the recipient. For example, criticizing a friend’s late behavior may challenge his or her desired identity as a good friend and responsible person. Both positive face (the desire for approval or to be perceived as competent) and negative face (the desire for autonomy or freedom from imposition) may be threatened by criticism. Criticism indicates disapproval (e.g., “You are not being a considerate friend”) and may suggest that the recipient should behave in a particular way

(e.g., “You should stop showing up late”). Certain topics of criticism (e.g., personal characteristics) threaten face more than others (e.g., behaviors) perhaps because the former are more stable and less likely to change. Both linguistic politeness strategies such as apologies, hedges (e.g., possibly, maybe), or claims of common ground through emphasis on commonalities as well as nonverbal politeness strategies (e.g., smaller gestures, positive facial expressions, softer voice) can mitigate the threat to face inherent in criticism.

In addition to identity implications, criticism may be perceived as a commentary on the relationship. A harsh, negative evaluation that leads to hurt feelings, for example, suggests that the critic does not value the relationship. Additionally, expressing criticism intersects with issues of power and control in relationships. Criticizing implies a certain right to evaluate. Some relational partners are more likely to have that right, either because of the nature of the relationship or because of their particular experience or knowledge. Parents, for example, are more likely to criticize than friends. In friendship, social norms grounded in the egalitarian and voluntary nature of friendship create expectations that friends will be supportive but not critical. Friends, then, experience a dialectical tension between being accepting and being honest that complicates providing criticism.

Although criticism can be well intentioned and helpful, critical behavior constitutes a component of hostile, destructive communication practices and patterns. Among these are verbal aggressiveness, social undermining, demand-withdraw conflict patterns, critical-rejecting parenting, and abusive relationships. Verbally aggressive criticism attacks the individual, and harsh criticism plays a part in psychological aggression. Criticism that invalidates the perspective or importance of the recipient is a part of social undermining, contributing to stress and anxiety for individuals. Criticism is also a key behavior in the demand part of the demand-withdraw pattern of conflict. In this conflict pattern, one person criticizes and blames (demand) while the other person avoids, defends, or responds passively (withdraw). Just as criticism in demand behavior may be an attempt to exert control in conflict, critical-rejecting parenting behavior can function to exert psychological control over children. Inaccurately perceived criticism

also occurs in damaging relational contexts. Abusive husbands, for example, tend to inaccurately attribute critical intentions to women when interpreting ambiguous behavior. Additionally, individuals vary in both perceptual (i.e., likelihood of perceiving a comment as a criticism) and emotional (i.e., likelihood of feeling hurt by criticism) sensitivity to criticism.

Responses to Criticism

The sequence of interaction following criticism also affects the outcome of criticism. Jess Alberts, a communication scholar who has studied complaints in marital interaction, suggested that a complaint functions as a conversational move that initiates an account sequence. The complaint is the reproach, challenging the relational partner, who then must provide an account. Types of possible accounts include justification-excuse, denial, agreement, avoidance, and countercomplaint. Recipients of a behavioral criticism are more likely to respond with justification whereas recipients of a dispositional criticism are more likely to deny the evaluation. More aggravating criticism (e.g., harsh, negative, or unfair statements) is more likely to elicit a defensive response (e.g., counterattack—"Who are you to talk? You don't always show up on time yourself!" or denial—"I am not always late"). In contrast, more affectively positive, fair criticism should elicit more agreeable responses (e.g., "I'm sorry; I didn't realize it bothered you so much; I'll try to be more aware of the time"). Communicating criticism in a way that minimizes the threat to desired social identities also reduces the likelihood of a defensive response.

Additionally, Alberts looked beyond the complaint-account to the larger complaint sequence. As couples progress through complaint sequences, they may reframe the complaint so that the complaint recipient no longer has responsibility for the issue, avoids the issue, is unresponsive to the issue, mitigates the significance of the complaint, escalates the complaint, or is responsive to the concerns expressed in the criticism. Relational context may shape the pattern of critical communication. More satisfied couples are likely to criticize behavior rather than personal characteristics and do so in a more positive manner. Dissatisfied couples, on the other hand, are more likely to

engage in unresponsive or escalating complaint sequences and more likely to respond to complaints with denial or countercomplaints.

Factors Affecting the Decision to Express Criticism

A number of different motives may prompt the expression of criticism in relationships, including a desire to influence a relational partner's behavior or attitudes, to provide helpful advice, to vent emotions, or to intentionally hurt the other. However, although a relational partner's characteristics or behaviors may be irritating or the individual may think that a partner should change his or her ways, individuals do not always express those evaluations. The potential outcome of criticism, power dynamics in the relationship, and expectations for appropriate behavior all affect whether or not an individual chooses to suppress or express a criticism. The likelihood of achieving the desired outcome of criticism in combination with the potential consequences influences the decision of whether or not to disclose a complaint. If an individual does not believe that the partner is likely to change his or her behavior and if the criticism is expected to lead to a negative outcome, such as conflict escalation or negativity, he or she is less likely to express the criticism.

Power and control can play an important role in the decision to express criticism. Punitive power (e.g., the potential for verbal or physical aggression) and dependence power (e.g., having poorer quality alternatives to the relationship than one's partner) may have a chilling effect in romantic relationships, leading individuals to suppress complaints for fear of the consequences. Individuals with better relational alternatives of their own, on the other hand, are more willing to criticize their romantic partners. The degree to which criticism violates relational expectations also may affect an individual's willingness to criticize. Friends, for example, are disinclined to criticize friends' romantic relationships unless the evaluation is solicited or the consequences of remaining silent outweigh the consequences of violating relational expectations (e.g., the friend is being hurt by his or her relational partner). There also are individual differences in the willingness to express complaints,

either because of their influence on the likelihood of experiencing dissatisfaction (e.g., people higher in negative affectivity are more apt to experience dissatisfaction and complain whereas people high in agreeableness are more noncritical) or their influence on expressiveness (e.g., extraverts generally are more likely to express feelings).

Consequences of Criticism

Criticism can have significant emotional consequences. Although partners may appreciate the insight provided by a criticism, individuals also may end up feeling regret over expressing criticism. Often, this regret comes from causing hurt. Hurtful criticism has a stronger impact if the hurt is perceived to be intentional. In addition to hurt, criticism can elicit feelings of anger and other negative affect. Recipients tend to experience anger in response to unfair or hostile criticism. Additionally, anger and hurt are more likely consequences of criticism that threatens face. Unresponsive or escalating complaint sequences also tend to create more hostility and frustration for relational partners than other types of complaint sequences.

Destructive criticism also negatively affects individual well-being. For example, social undermining, which includes overly critical behaviors, contributes to the psychological distress of individuals experiencing stress. Similarly, having a critical spouse is related to depression, and critical family environments can negatively affect mental health.

Communicating criticism can influence relational quality as well. Destructive criticism undermines intimacy in relationships. John Gottman's research on marital communication, for example, identifies criticism as a particularly corrosive behavior during marital conflict, a warning sign for marital difficulties. Gottman uses the term criticism in a narrow way, specifically referring to global statements attacking a spouse. In his research, this type of criticism has been shown to be destructive for relationships, particularly if it occurs frequently and leads to other behavior, such as defensive responses and cross-complaining. This type of critical communication also tends to be damaging in other types of relationships (e.g., parent-child) as well, negatively affecting relational satisfaction.

Face-threatening criticism is more damaging to relationships than criticism that is attentive to identity concerns. Certain types of complaint patterns are more destructive for relationships than others. For example, complaints followed by a countercomplaint or by withdrawal are particularly damaging pattern of interaction in romantic relationships. In contrast, research on accommodation in relationships demonstrates that a constructive response to a destructive criticism may mitigate the negative outcomes for a relationship.

CULTURE AND RELATIONSHIPS

Our understanding of the interface between culture and relationships is in its infancy. This preliminary level of knowledge results from the

traditional research focus on the separate individual that has underemphasized relationships and their crucial importance in human life; cross-cultural social psychology has inherited this narrow emphasis that places the individual at the center of the behavioral drama. In consequence, there is a sparse cross-cultural database on relationships to integrate, and this available information may be inappropriately framed to promote the understanding of relationships. This entry explores how relationships have been approached by cross-cultural psychologists, selects examples of key research, and suggests future approaches to illuminating this interface.

As individuals striving to survive and flourish in a complex ecological system, people need others to support their inadequate and incomplete efforts at meeting their human requirements for living. The resources provided by others are crucial in enabling people to meet their physiological and security needs as well as satisfying their demands for social contact, dominance, and meaning or purpose in life. To ensure that these goals are met, human beings require the cooperation of others. Properly socialized members of a community contribute toward maintaining their reciprocal relationships with needed others and promoting the social system by which that community of relationships is sustained. From a relational perspective, culture may be understood as a community's norms, beliefs, and values informing the matrix of people's interdependencies with others, as each member moves through the life cycle. Cultures will vary in the emphases they give to these psychological processes that guide people's interpersonal behavior.

Why Culture?

Social science needs the concept of culture because evidence from geographically separated communities has shown that how these interdependencies are managed varies from place to place. For example, David Matsumoto has orchestrated a team of researchers from 32 cultures around the world to explore how emotions are displayed to others. Emotional expression plays a crucial role in regulating ongoing social interaction, so variations in the dynamics of this regulation will have important consequences for how relationships are

managed. These researchers found that in all cultures emotional display is sanctioned more toward outgroup members compared to ingroup members and when the person displaying emotion was in a public setting as opposed to being alone with an interacting partner. Regardless of the social setting, however, persons socialized into individualistic cultural systems, where freedom and equality are more highly valued reported greater freedom in expressing their emotions, particularly positive emotions; persons socialized into collectivist cultural systems, where self-restraint and social order are more highly valued, reported less. In this domain of relationship, then, a respondent's cultural group membership influences his or her level of emotional expressivity.

As another example, Michael Bond and Joseph Forgas explored whether the perception of another as more conscientious led the perceiver to engage in more trusting behaviors toward that target. They confirmed this expectation but found that conscientiousness was more influential on Chinese than upon Australian trust. In this case, a respondent's culture affected the strength of association between another's personality characteristic and an actor's behavior toward that person, shaping a dynamic process. As before, the emphasis on self-restraint characterizing a collectivist culture enhances the importance of the personality characteristics that are more valued in its members and hence directs its member's behavior toward those others. It is these empirical demonstrations of culture's association with relationship-relevant outcomes or processes that drive the scientific search for explanations about why cultural membership affects people's associations with other persons.

Relating Culture to Relationships

In developing their theories, psychologists have been guided by previous work on cultural differences in values, beliefs, and self-construals, all constructs that characterize the individual members of a relationship. Values refer to what end products or goals are deemed important by persons from different cultural groups. Shalom Schwartz has identified a pancultural structure for general values along which persons from different cultural groups may be positioned. The value

domain of universalism taps a person's concern for peace and brotherhood, for example, and varies across the world in terms of its relative strength of endorsement, being relatively high in Portugal and Greece but low in Slovenia and China. Persons valuing universalism are less likely to be prejudiced and hostile toward outgroup members, so in cultural groups where universalism is endorsed, there is less interpersonal negativity toward outgroup individuals, making relationships less fraught with difficulty.

Beliefs are assertions about the truth of a connection between two entities, such as the statement that religions promote warfare. As with values, general social beliefs have been studied in over 40 cultural groups by Kwok Leung and Michael Bond and shown to vary in their level of endorsement across five fundamental dimensions. These beliefs about the world impact the way a person processes conflict, with persons higher in social cynicism reporting less use of collaboration and compromise during interpersonal conflicts with others. One would thus predict that people in a culture that socializes its members for higher levels of social cynicism, such as Estonia, would be characterized by less harmonious interpersonal relationships.

Another widely researched way of distinguishing persons of different cultures is through their self-construals. Based on the social logic characterizing collectivist and individualistic cultural systems, Hazel Markus and Shinobu Kitayama described the constructs of interdependent and independent self-construal to tap a person's orientation toward promoting group integrity and personal ascendancy, respectively. A higher level of interdependent self-construal, for example, has been shown to predict one's capacity to be embarrassed on behalf of another, the suppression of negative affect during interactions, and the use of an indirect style of communication with interaction partners. In contrast, a higher level of independent self-construal has been shown to predict being less embarrassed by one's own actions, an increase in expressing positive emotions with others, and a more direct style of communicating. These are important features of relationship management that promote the attainment of relationship harmony and productivity with significant others, respectively. Given that the strength of these two self-construals has been shown to vary

across members of different cultural groups, the typical way relationships are conducted also varies across these cultural groups in ways predictable from their emphases during socialization.

Culture and Relationshipology

The forgoing research flows seamlessly out of the general Western intellectual focus on the individual; it examines how the individual characteristics of dyad members affect individual psychological outcomes, such as satisfaction with marriage, for example. As a counterpoint to this academic reflection of individualism, David Ho has called for the development of a discipline called *relationshipology*. In this discipline, the focus of interest is not on individual personalities—attributions and interpersonal styles—but on the relationship itself—its characteristics and outcomes. This academic focus on the higher-order units constituted by individuals but transcending its individual members is believed to flow from the holistic features of Eastern, especially Taoist, thought. Such an orientation has characterized some mainstream work on relationships, but Ho's challenge has galvanized cross-cultural researchers to design studies that illuminate this differential cultural emphasis.

An example of this shift in focus involves work examining the pattern of interaction between a dyad's members and the impact of that patterned interaction on that relationship outcome. In this vein, Chester Kam and Michael Bond examined how the target of another's harmful act dealt with the face loss that followed from being attacked. They discovered that both American and Chinese targets responded to being harmed with feelings of shame. The greater that shame, the greater was the tendency of the target to withdraw from the relationship. That degree of that withdrawal predicted eventual dissolution of the relationship. Losing face by being harmed led to target anger and to eventual relationship deterioration, but more strongly so for Chinese than for Americans. Evidently, then, culture can exercise an impact on the processes by which relationships flourish or fail.

Culture exercises its influence on such individual responses in a relationship and on how certain key relationships are formed. Since the pioneering

work of John Bowlby on attachment, cross-cultural developmental psychologists have been exploring features of the parent-child bond. As Ron Rohner has demonstrated across 100 cultural groups, there are large variations in the level of warmth characterizing this basic relationship during the child's developing years. Such parental acceptance influences the maturing child's subsequent capacity to form emotionally stable, generous, and trusting relationships with other adults, as opposed to forming dependent, emotionally charged, and hostile associations. In a 62-culture study, David Schmidt and his collaborators showed that the reported preference for a secure form of adult romantic attachment characterized 79 percent of their extensive sample of respondents. However, its normativity was not universal but varied across their cultural groups, with persons from East Asian cultures in particular valuing a preoccupied style of attachment. This finding suggests that the long-standing Western model for adult romantic relationships is presumptuous and that certain cultural dynamics may press toward alternative but equally workable forms of heterosexual relating. It is important to discover what societal factors shape preferences for different relationship styles and whether these relationship styles have the same or different consequences in different cultural systems.

Culture has also been shown to affect how various relationships are construed in the first place. Relationships are units of two persons engaging in complementary interpersonal activities called roles. There are many such role dyads in a given social system, from mother-daughter to prosecuting lawyer-defense witness, but culture socializes its members to enact these dyadic complementarities differently. Researchers have assessed various objective features of the interactions typically undertaken by many role dyads, such as how frequently it meets, who controls the exchanges, and whether the dyad is visible to others. The researchers found that the same four dimensions characterized any given dyad in both Australian and Chinese cultures—its degree of complexity (range of activities), of equality (degree of hierarchy), of adversarialness (formalization of conflict), and of containment (privacy of transactions). In both cultures, a father-son dyad was high in complexity, low in equality and

adversarialness, and moderate in containment. So dyads, like individuals, have personality profiles defined by their relative position on these four dimensions.

However, cultural differences also appeared. The Chinese showed a higher degree of difference across the role dyads on the equality dimension, reflecting the greater degree of hierarchy institutionalized in Chinese culture and practiced within its dyads. Conversely, the Australians showed higher variation on the adversarial dimension, reflecting the greater competitiveness institutionalized in Australian culture and practiced within its dyads. Given these differences, it was not surprising that particular role dyads (e.g., bank manager-customer) showed different interaction profiles in the two cultural groups. Culture thus shapes how people relate to one another in dyadic relationships to do the work of daily life.

For any relationship to work, its members must share expectations of what and how they each must do their relationship. Socialization into a cultural system ensures an adequate level of shared norms so that members of that cultural system can maximize their cooperation and minimize their opposition to one another's claims from the relationship. Despite the importance of relationship rules, they have been subject to little cross-cultural examination. Michael Argyle and his collaborators looked at general relationship rules in four cultures. Unfortunately, they did not examine the degree to which these rules were shared and enforced by members of their culture. Future cross-cultural work needs to explore these basic issues about the norms informing relationships and needs to explore them in many more cultural groups. A comprehensive taxonomy of relationship norms would enable psychologists to profile these different cultures, examining the societal conditions leading to this relationship profile and to examine the consequences of relationship norms and their sharedness for relational outcomes in different cultural contexts.

DAILY DIARY METHODS

Daily diaries are a research method used to study individual or relational processes in daily life outside the laboratory. The term *diary* refers to self-report questionnaires, administered repeatedly over days or weeks, either daily or with some higher (e.g., 3–5 times within-day) frequency. Related terms include ambulatory monitoring, experience sampling method, and ecological momentary assessment.

Unique Features of Diary Methods

In the area of close relationship research, diary methods are used to study various phenomena, such as rates and effects of supportive and hindering acts, associations between responsiveness and intimacy, sexual behaviors and motivations, emotional experiences and their transmission to others, and empathic accuracy. To illustrate the latter, couples might be asked to complete daily reports of their own mood along with inferences about their partners' moods; these reports are then cross-matched to determine general levels of inferential accuracy as well as individual and contextual differences in these.

The frequent reports obtained with diary studies enable monitoring particular feelings, cognitions, actions, or situations in the real-life contexts absent from traditional research designs. These fleeting states or events are monitored while or soon after

they occur. This highlights the first generally accepted benefit of diary methods: They circumvent the need for retrospection or for reliance on respondents' beliefs about themselves or the world and instead capture transient states as they are lived and felt. The importance of this benefit has been made clear by work showing that when people attempt to report their feelings, the length of the period of time about which they are responding affects the way in which their response is generated. Reporting one's momentary mood can usually be done quite easily and with acceptable validity. However, when reporting their mood over, say, the past few days, individuals do not simply access their memories of these states but instead may rely on their chronic beliefs about their mood or temperament. Moreover, when respondents do try to aggregate subjective feelings over some time, they tend to overemphasize certain moments (e.g., the emotion felt while providing the rating) and as a result, supply less reliable or valid estimates than those obtained by actually monitoring feelings repeatedly. For example, in an uncomfortable medical procedure, patients' subsequent evaluation of pain in the procedure is most strongly related to peak levels of pain felt during the procedure and to the pain at the very end of it and not to a real aggregate of the pain or its duration.

When transitory states (such as positive or negative mood, thoughts of acceptance or rejection), behaviors (e.g., providing or seeking support), or events (e.g., interactions with an opposite-sex person) are monitored repeatedly within a diary study, researchers reap a second benefit: collecting

information on the intra- and interpersonal context of these states. Because diaries are completed in the course of everyday life, they open a window to examining many important contextual effects on the variables of interest. For example, a health researcher may want to know whether situational features (e.g., presence of peers) distinguish moments in which a particular behavior (e.g., smoking) occurs. Similarly, a relationship researcher may want to examine whether empathic accuracy increases when spouses are asked to intuit their partners' moods when apart (e.g., at work) or together (e.g., at home).

A related benefit of diaries is their ability to inform us about processes unfolding over time. Because the same feelings, cognitions, or events are assessed repeatedly, researchers can see whether particular patterns (e.g., weekly or circadian cycles) emerge; for example, positive moods do follow a circadian rhythm, while negative moods do not. And by monitoring processes as they unfold, researchers can recognize antecedents, concomitants, and consequences of particular states. This is often done using lagged analyses in which outcomes (measured at time t) are predicted by variables measured in the previous diary (i.e., at time $t-1$). For example, a positive mood one day could be a function of capitalization—celebrating positive news with a responsive partner—on the previous day. In the typical case, such lagged analyses also adjust for the outcome's level on the previous day (e.g., positive mood yesterday); this adjustment helps rule out the possibility of reverse causation (e.g., that positive mood yesterday led to sharing good news today as well as to positive mood today).

Another useful feature of diary data is their ability to clarify the within-person structure of particular constructs (e.g., the within-person association between positive and negative moods) as well as individual or group differences in this structure. Within-person structure does not necessarily follow between-person structure: The former looks at how certain qualities are associated within an individual's experience from one time to another, whereas the latter looks at how certain qualities of individuals' general experience relates to other qualities. For example, positive and negative affect are mostly unrelated in cross-sectional survey analyses, but at the within-person level, may have negative, null, or even positive associations. This

within-person association between positive and negative moods has been shown to depend on several factors, including social cognitive aspects of the particular person as well as his or her cultural mind-set. In the absence of repeated data within persons, these important individual differences in structure would be impossible to detect.

Diary Study Designs

There are two broad classes of diary studies—event-based and time-based. In event-based diary studies, participants complete diaries whenever certain events (e.g., an interaction lasting more than 10 minutes, an urge to engage in an unhealthy behavior) occur. This design is particularly useful for studying events that are rare, specialized, or would not be expected to occur with fixed or predictable frequency. For example, one study examining the link between personal disclosures, responsiveness, and intimacy used this design because it allowed asking a set of detailed questions immediately following every social interaction for as few or as many such interactions as participants had over 1 week. The study in question employed an event-based diary that has been widely used in close relationship research: the Rochester Interaction Record.

Unlike event-based designs, time-based studies ask the respondent to complete diary entries at fixed or random time intervals (e.g., once every evening or 5 times a day at semirandomized times). Diary studies using time-based designs are more common in part because they provide data that are more consistent across participants (who all respond with the same frequency). Uniform or balanced data of this sort are useful when making generalizations regarding aggregate levels of an outcome variable (e.g., average daily felt intimacy) or when applying the lagged analyses described above in a way that allows for a fixed interval of time underlying lagged effects. They are also useful in estimating the frequency of certain events (e.g., support, hindrance) in a sample.

Time-based studies often make use of signals to prompt responses at particular fixed or random times, especially in studies that involve several responses per day. In early studies, signals often involved preprogrammed wristwatches, pagers, or phone calls made to the participants, who then

completed paper-and-pencil diaries. With recent technology, participants signaled in this way might use Interactive Voice Response or simply key in their responses on dial-pads. In the past decade, many diary studies have incorporated electronic personal digital assistants—hand-held computers outfitted with software for signaling participants, presenting questions, collecting responses to them, recording the response time, and storing these responses until the researcher downloads them (or transmitting them immediately, in some software versions). With some study populations, diaries can also be presented through the Internet (assuming that participants have easy access to networked computers at those times that are sampled—an assumption that is easier to make with the advent of Internet-enabled mobile phones).

The questions being investigated determine numerous design decisions. They guide the choice of event-based or time-based diaries (and for the latter, ones using fixed or random signals). They involve optimizing the frequency with which diaries are presented (e.g., once daily, 5 times daily, every hour) and the total length of the diary period (a month, a week, 1 intensive day). They determine which relevant and contextual questions should be included (while remaining mindful of participant burden and compliance). And they require choosing whether to use self-reports exclusively or to incorporate psychophysiological or other collateral assessment. For example, health researchers sometimes outfit their subjects with both electronic diaries and ambulatory blood-pressure cuffs, allowing synchronized self-reports and physiological assessments; similarly, communications researchers sometimes collect self-report diary responses alongside unobtrusive voice recordings that capture natural speech samples.

Data Analysis in Diary Studies

The data collected in diary studies are, by definition, multilevel in nature: They include repeated assessments (often called level-1 units) nested within individuals (level-2 units), who themselves might be nested within some superordinate category (e.g., couples, groups, experimental conditions—or level-3 units). The last 2 decades have brought the development of specialized data-analytic techniques

that are suited for such nested data. These techniques come under several names (multilevel modeling, general mixed models, random regression, or hierarchical linear modeling are the most common terms) but are essentially similar. Their strength lies in appropriately handling some of the key features of multilevel diary data, including the statistical interdependence between repeated measures taken from the same individual (typically indexed by the intraclass correlation), the common problem of unbalanced data (i.e., data in which different individuals have varying amounts of diary responses), and the freedom to incorporate statistically both within-person and between-person predictors.

Limitations of the Diary Method

The field's excitement about diary methods and the growing ease with which they can be implemented have led to an exponential growth in their use as well as in the availability of methodologies for administering them and for analyzing the data they provide. However, some authors note the difficulties in implementing these studies. Diaries can be burdensome to participants, who are asked to respond repeatedly to questionnaires at times that may be inconvenient. This burden can result in problematic compliance—partial, or worse, selective responses to the diaries. Additionally, the effects of these designs are not yet well understood. A particularly relevant, commonly expressed concern about diary studies is that, by focusing respondents' attention on certain phenomena (their mood, events within their relationships, their healthy or unhealthy behaviors), the studies can inadvertently change these very phenomena of interest—a version of the observer effect or of reactivity. To date, few studies have found this anticipated reactivity, and several have provided reassurance that diary reports can be trusted as well or better than other forms of self-reports, such as those collected in cross-sectional or in longer term panel studies.

Expanding the Utility of Diary Methods

Two extensions, both involving the combination of diary methods with additional methodological approaches, promise to amplify the benefits close

relationship researchers can draw from diary methods. The first involves using diaries in conjunction with other forms of data collection within the same study to illuminate research questions from multiple perspectives. For example, researchers interested in sexual behaviors and beliefs in newlyweds may approach this question using both cross-sectional and longitudinal survey methods (e.g., assessing sexual experience and beliefs close to marriage and again as they unfold over some period of months or years), daily diaries (e.g., monitoring sexual motivation, initiation, and behavior), and lab-based observations (e.g., examining the couples' communication about sexual and nonsexual topics). Each of these methods contributes a different outlook on the same multifaceted topic, and together they allow determining whether phenomena found in the lab also occur in the couples' naturalistic environment.

A second expansion integrates self-report measures with collateral forms of data from the individual or their physical-interpersonal environment. One form of diary methods mentioned earlier—ambulatory monitoring—does just that, by simultaneously collecting self-reports (of feelings, cognitions, or behaviors) with psychophysiological data, physical movement recordings, unobtrusive audio recording, digital snapshots, or even location tracking (using global positioning [GPS] methods). For example, researchers interested in talkativeness in natural conversations as it relates to self-reported goals or moods could outfit their participants with devices (already available) that collect voice samples unobtrusively and present diary questionnaires in either an event-based or a time-based manner.

A third direction for further use of diary methods is in delivering behavioral or cognitive interventions. Diaries can include brief reminders or instructions for participants to monitor behaviors or use strategies or skills in their daily lives. For example, interventions aimed at life-style change (relaxation, exercise, smoking cessation) can use diaries to monitor a subject's behaviors and provide preprogrammed feedback. They can also monitor adherence to such instructions (i.e., whether a particular assigned behavior, such as a relaxation or breathing exercise, was carried out) and assess responses or consequences to their use.

DARK SIDE OF RELATIONSHIPS

The *dark side of relationships* is a catchphrase intended to capture a broad set of inquiries into the nature and functioning of personal relationships. At its most general, the phrase refers to the scholarly interest in the ways in which humans experience dysfunction or functional ambivalence in the process of relating. Dysfunction is viewed as organisms failing to achieve optimal or preferred states of existence, and functional ambivalence refers to any process that moves individuals or relationships both toward and away from such states of existence. The dark side shares concerns and interests with historical scholarly pursuits in the philosophical study of human nature, abnormal and clinical psychology, the sociology of deviance and aggression, and rhetorical exploitation and incompetence. Given such expansive associations, it is not easily defined. The following sections trace the historical roots of the dark side metaphor and summarize the evolution of dark side terminology. The entry reviews the topical

content of dark side literature and offers an assessment of the utility of the dark side metaphor for relationship scholarship.

History

Historical examinations of the dark side concept reveals diverse multidisciplinary roots. The development of the concept of seven deadly sins (lust, gluttony, greed, sloth, wrath, envy, and pride) and their comparative virtues (e.g., chastity, temperance, charity, diligence, patience, kindness, and humility) illustrate a historical interest. The prospect that the seven deadly or cardinal sins might be part of human nature inspired artistic, philosophical, and religious inquiry into this nature. As inquiry evolved into the study of relationships, the prospect that evil and sin may be integral to understanding relationships became apparent as well. Thus, as academic disciplines evolved, so did the interest in the dark side. The field of communication was born out of the debate between Plato and Aristotle, in which Plato feared the relegation of rhetoric, often viewed as nothing more than an art, to the status of a science because of the ability of persuasion and manipulation to distort and distract people away from scientific truth. Plato's student, Aristotle, argued instead that the only way to avoid such victimization by the arts of rhetoric was through its systematic study—understanding manipulation and exploitation can help prevent it. In more contemporary times, the field of psychology continues to devote an entire domain of inquiry into abnormal psychology. Sociology continues to demonstrate an interest in conflict, deviance, and alienation as significant themes of the discipline. Communication criticizes the misuse of communication and attempts to remedy various forms of relational incompetence. Most disciplines have some facet that is significantly devoted to the study of dysfunction, including the study of families, organizations, politics, history, and health. Despite these deep disciplinary roots, the modern study of the dark side has largely been fragmented and lacks thematic coherence.

The Evolution of Terminology

In popular consciousness the phrase the dark side is often associated with its extensive use in the

Star Wars movies beginning in 1977, and at least one online dictionary actually attributes its etymology to this source. Although clearly popularized by the movie, the phrase predates its usage in this epic. In the social sciences, numerous terms and phrases have been applied to the study of dysfunctional relationships, including the dark side of families, courtship, interpersonal communication, close relationships, and organizational behavior. Other cognate phrases include relating difficulty, inappropriate relationships, aversive interpersonal behavior, behaving badly, counterproductive work behavior, problematic relationships in the workplace, troublesome relationships, psychological problems, emotional and behavioral problems, the social psychology of good and evil, and the science of good and evil. This network of associations reveals a key aspect to the evolution of this area of study: the need for a metaphor or label for integrating a general interest in the investigation and understanding of the dysfunctional aspects of human interaction and relationships.

In large part, there were two interrelated motives for introducing such phrases. First, there was a need for topical coherence. It was recognized that there was a significant amount of scholarly research that provided insight into the dysfunctions of relationships that had no obvious rubric under which to be referenced. Academic disciplines have never ignored topics relevant to the dark side. Any perusal of the scholarly landscape in the social sciences reveals interest in the study of psychosis, depression, suicide, violence, aggression, murder, war, crime, conflict, shame, guilt, repression, deviance, deception, coercion, threat, incest, taboo, secrecy, infidelity, misunderstanding, exploitation, prejudice, alienation, jealousy, and any number of other forms of dispreferred experiences. These topics, however, had never really had a scholarly home, a single roof under which such topics could be collectively examined for their implications about human relationships. The introduction of the dark side into the scholarly discourse drew attention to the possibility that these diverse contexts are not entirely discrete or independent of one another. In studying one, insight into the others might benefit.

The second motivation for the dark side grew out of a suspicion of a positive ideological bias that needed balancing. There was a sense that the

darker side of relationships tended to be overlooked because of a tendency toward relationship theories that were overly optimistic or biased. For example, marriage counseling literatures tend to start with the assumption that marriage itself is a desirable institution. Most therapies presume that rationality and consistency are preferable to irrationality and inconsistency, perspectives that demote the roles of affect in decision-making and the plasticity of self. Theories of relationships tend to presumptively privilege intimacy over nonintimate relations and presumptively treat relationship dissolution as a problematic experience. These ideologies of soundness and togetherness represent often subtle and implicit value systems that privilege optimism, stability, commitment, and interpersonal closeness.

As the field of personal relationships initially borrowed heavily from preexisting theories of human nature, it tended to emphasize the study of voluntary relationships, motivated by attraction, love, satisfaction, and the pursuit of mutuality, understanding, and cooperation. The underlying ideology of much of the social sciences, undergraduate textbooks, and the popular press of personal relationships continue in large part to privilege the desirability of empathy, accuracy, clarity, expression, openness, secure attachment, trust, cooperation, relational satisfaction, and collaboration. These concepts are often implicitly taken for granted as desirable qualities of relationship functioning, and positive correlations among such concepts are taken as confirmation of such presumptions. Whereas many if not most of these processes and states do indeed demonstrate positive functions, what often get ignored are the conditions in which they are dysfunctional. Although the research is not extensive, isolated studies suggest that highly empathic people are easily exploited in negotiation contexts, highly trusting persons may be exploited in game scenarios, high self-esteem persons may also be more defensive and aggressive when insulted, polite people may have a hypersensitivity to rule violation that triggers violence, and highly attractive persons may suffer discrimination from those who presume that talent and appearances are unlikely partners. The development of the dark side was an attempt to cast a critical eye on such presumptions.

The Dark Side to Date

Although the dark side of relationships can be defined from theoretical and epistemological points of view, most commonly it has been explicated through particular research topics. Topical approaches presume or demonstrate the unpleasant or dysfunctional nature of certain phenomena and then examine a selected set of topics that exemplify these phenomena. Examination of existing topics devoted to the dark side include, but are not limited to, the following: general aversiveness (e.g., aversive interactions, counterproductive behavior, negative communication, evil), aggression-violence (e.g., psychological abuse, sexual abuse, child abuse, parent abuse, sexual coercion, threat, rape, stalking, violence, aggression, genocide), aversive behaviors (e.g., gossip, rumor, mobbing, bullying, emotional abuse, psychological abuse, guilt induction, embarrassment induction, hurtful messages or feelings), rejection and disjunctive relationships (e.g., hurtful messages or feelings, complaints, criticism, incivility, social ostracism, rejection, unrequited love, neglect, outgroup bias, racial bias, hostility, swearing and blasphemy, teasing, breaches, transgressions, betrayals, infidelity, fatal attractions, unrequited love, friendship deterioration, relationship breakup and divorce, discrimination, injustice, harassment, revenge, enemyship, obsessive relational intrusion), negative affect (e.g., shame, guilt, jealousy, envy, anger, stress), problematic persons (e.g., difficult others, troublesome others, personality disorder, depression, social anxiety, shyness, schizophrenia, alcoholism, sexual dysfunction, egotism, narcissism, dysphoria, selfishness, cynicism, deviance), problematic relations (e.g., in-laws, hookups, long-distance relationships, unwanted relationships, secret relationships, interracial relationships), taboo relationships (e.g., therapist-patient sexual relationships, pedophilia, necrophilia), and problematic communication (e.g., dysfunctional or exploitative impression management, manipulation and exploitation, lies and deception, uncertainty, secrets, manipulation, misunderstanding, computer-mediated communication, conflict, codependence). These are obviously not mutually exclusive topics, and the overlaps suggest the possibilities of a more systematic mapping of the underlying structure of the

dark side as it is charted in the personal relationships discipline.

Prospects

Judging from the amount of published research relevant to the dark side of relationships, the concept appears to have had heuristic value. Given the rather cumbersome and ever-expanding list of topics imported into its metaphorical umbrella, however, there is reason to ask what the disciplinary value of the concept has been and will continue to be. The value of the concept can be examined on three levels: empirical, theoretical, and metatheoretical.

There is no simple way to quantify the impact of the dark side perspective on research in the field of personal relationships. Although there is evidence that a dark side perspective has sustained a thematic trend of research, there is only limited evidence that it has directly inspired new investigations or theories. At the metatheoretical level, however, interest in the dark side appears to have had some influence. At this level, the dark side is not a topic or a theory but a perspective, or way of viewing the world. From the dark side perspective, which assumes that all social processes are multifunctional, no systematic investigation should ignore the possibility that bad outcomes may occur even when good outcomes are expected and that good outcomes may occur even when bad outcomes are expected. Specifically, the dark side perspective calls attention to the fact that a discipline needs to be cautious about its ideological presumptions and to allow for the possibility that relationship processes are always potentially functionally ambivalent.

One tool for identifying the boundaries of the dark side consists of the intersection of two dimensions: normative value and functional value. Normative value refers to cultural, societal, institutional (e.g., religion, political), or individual subjective evaluations of behavior as productive or destructive. Behavior can be normatively viewed as good, moral, ethical, or productive on one end of this continuum, and bad, immoral, unethical, and destructive on the other end of this continuum. Functional value refers to the extent to which activities enhance or detract from the ability of an

organism or relationship to live, survive, and thrive. When crossed, four quadrants are formed.

The bright side quadrant consists of activities or experiences that are normatively viewed as positive and function to enhance the individual or relationship. A pure exemplar may not exist, but candidates might include secure parental attachments to children and affectionate behavior exchange among romantically attracted consenting adults. The what-once-was-bright-is-now-dark quadrant includes functionally destructive activities or experiences that are normatively viewed as good or productive. Exemplars might be self-esteem that is destructive or physical attractiveness that elicits damaging stereotypes. So enamored are scholars with the evidence of value of self-esteem and physical attraction that only recently and rarely have scholarly efforts attempted to redress the oversight by investigating the conditions under which these conditions can be destructive. The what-once-was-dark-is-now-bright quadrant consists of activities and experiences that are normatively viewed as wrong or destructive but that actually function to enhance the individual or relationship. Exemplars exist such as sexual abuse victims who perceive benefits to their relationships with their own children or survivors of battering who perceive that they have become stronger and more self-reliant when they leave the relationship. Less extreme examples would include investigation of how intentionally making partners embarrassed or jealous serve a variety of ends, including influence, instruction, and intimacy. For example, people who intentionally seek to make their partners jealous tend to believe that the relationship improves in part because the partner changes for the better to enhance their attractiveness to the jealousy inducer. Relationships may function better to the extent that some distrust and deception are sustained, so as to keep the partners more careful and less biased in their attribution of motives and meanings to one another. The evil incarnate quadrant refers to activities or experiences that are both normatively viewed as wrong or destructive and indeed function to detract from the individual's or relationships capacity to survive and thrive. Exemplars would probably include acts such as mass murder and genocide.

The value of such a heuristic is that it calls attention to the importance of including constructs

in research programs that might otherwise be presumptively overlooked. If it is presumed that relational violence is wrong and functionally destructive, then the potential beneficial outcomes will not be measured, and will not be identified. By identifying those who are able to experience positive outcomes from trauma, the factors that differentiate these people from the more negatively affected individuals can be better understood, and better treatments and interventions can be developed. Yet to suggest studying the benefits of child sexual abuse in order to identify such differences, even when clearly admitting the net damage that such trauma causes, is sufficient to elicit great resistance in disciplines. In this sense, ideology is preserved by exclusion, and the resulting biasing effects on research are relatively invisible in a program of empirical investigation.

Although they represent a minority of scholarly studies, there are investigations of the disadvantages of impression management, cooperation, altruism, attractiveness, love, disclosure, interdependence, cognitive complexity, empathy, and other concepts traditionally viewed as positive. There are also studies of the advantages or perceived benefits of experiencing various forms of victimization, aggression, anger, jealousy, breakup, isolation, and madness. Empirically exploring the functionally ambivalent features of relationships may be viewed as threatening to political and disciplinary agendas, but if the ultimate goal of science is understanding, then the dark side perspective reminds that ambivalent functionality of social processes needs to be understood both theoretically and empirically.

DATING, FIRST DATE

Contemporary courtship typically relies on dating as a way to initiate romantic relationships in the United States and in many other countries. Dating refers to informal interactions between two individuals with the implied intent of assessing each other's romantic potential but has no specific commitment or goal. A graduated series of dates is considered the first step to a serious romance. The purpose of this entry is to describe sexual scripts for a first date, address how gender and sexual orientation affect the first date script, and briefly discuss some newer forms of first dates such as Internet and speed dating.

A first date is an easily identifiable and widely experienced event among young adult heterosexuals. Most of the research on first dates uses Script Theory as a framework. Scripts refer to the routine actions involved in familiar activities. For instance, "look at the menu" and "order food" would be

some routine actions or script elements that would occur when eating in a restaurant. Sociologists William Simon and John Gagnon proposed the concept of sexual scripts as a blueprint for guiding sexual behavior specifically. Sexual scripts operate on three distinct levels: Cultural scripts refer to collectively developed scripts, interpersonal scripts refer to the use of a specific cultural scenario by an individual, and intrapsychic scripts pertain to private wishes and desires. Recent interest has focused on whether cultural scripts regarding gender roles in dating continue to guide interpersonal scripts and what new scripts or forms of dating are developing.

Cultural scripts for the first date are explicit, formal, and have remained stable over the past 40 years. A defining feature of the first date is its gender etiquette. This may be because the tendency to pose or conform to stereotyped gender roles is a characteristic of beginning heterosexual romantic relationships. Men are to initiate, plan, and pay for the date; engage in courtly behavior such as opening doors; and initiate sexual contact. Women are to fulfill a subordinate role by being alluring, engaging the man in conversation, and limiting sexual activity.

In research conducted on mostly White college students, young adults' descriptions of a hypothetical first date were found largely to conform to the cultural script of male initiation–female reaction. For instance, when listing the actions a woman [or man] would typically do on a first date with someone new, young adults described self-directed actions such as “decide what to do” and “initiate physical contact” as being unique to the man's script. Actions unique to the woman's script involved reactions such as “wait for date” and “accept [or reject] the man's moves” such as an “arm around shoulder” or a “kiss.” These findings suggest that the cultural script for a first date is very strong and familiar to young heterosexual adults.

Actual first dates closely conform to abstract cultural scripts. When women college students described a recent actual first date, 14 actions referred to what she did on the date (e.g., “groomed and dressed” and “talked, joked, and laughed”), and 6 actions were initiated by the man: “picked up date,” “opened doors,” “took date home,” “asked for another date,” “told date he would call her,” and “kissed goodnight.” Men described

15 actions and all were self-initiated. Thus, actual first dates were highly similar to the cultural script in terms of defining the man's role as active and the woman's as reactive.

Sexual behavior on a first date is influenced by certain contexts. For instance, actual first dates that were initiated by men had more sexual activity than first dates that were initiated by women. Also, more sexual behavior occurred on actual first dates when alcohol was consumed. More sexual activity was used to describe a hypothetical date occurring “at a keg party” than one occurring “at a coffee shop.” This difference suggests that both the cultural script and the actual behavior of young adults vary depending on the context of the date.

An interesting question regarding the cultural dating script concerns how it affects lesbians and gay men. Similar to heterosexual gender roles, gay men who described both a hypothetical and actual first date mentioned more sexual actions (“make out” and “have sex”) than lesbians, whereas lesbians more often than gay men mentioned “positive affect” for the date and “get to know/evaluate date.” Lesbians and gay men also were not likely to introduce a date to family or to show affection in public. However, active or reactive gender roles were not assigned to one person. On a same-sex date, either person was free to pick up the other person, pay for the date, or initiate sexual contact. Thus, personal abilities or desires, more so than gender roles, appear to guide both dating scripts and actual behavior for lesbians and gay men.

Some newer forms of first dates include speed dating and Internet dating. Speed dating is a phenomenon that refers to a brief series of dates typically lasting from 3 to 8 minutes that an individual may have with others attending an event. If both wish to meet each other when time is up, they are told how to contact each other for a future date. Conformity to a gender-typed dating script is likely to be important to success in speed dating. Internet dating occurs through chat rooms or other social networking groups and has the advantage of allowing people to get to know each other without the time and effort involved in an initial face-to-face meeting. It also may reduce the relevance of gender conformity and physical attraction in initial attraction.

In sum, a first date is strongly influenced by a highly gender-typed cultural script. Heterosexuals

tend to adhere to the cultural script in order to create a good impression. The script is less influential for same-sex and online dating, where more private desires and interests may be expressed.

DATING AND COURTSHIP IN MIDLIFE AND LATER LIFE

Dating and courtship in midlife and later life are relatively new phenomena. A confluence of factors explains why. For one, until recently, few people lived to what is now considered midlife. In 1900, life expectancy was 47, and by age 50, most people were dead! Life expectancy in the United States today is 77 years. Better health, preventive care, and life-extending technology enable more and more people to live to their 80s and 90s. Midlife begins around age 40 or 45 and lasts through age 60 or 65. More people today than ever do not feel old at age 50 or 60. This entry explores dating and courtship in midlife and later life, how they came about, how people feel about them, how they differ from dating at younger ages, and dating practices.

Besides the accumulation of years, changes in mores, attitudes, and values have paved the way for dating and courtship among single men and

women in midlife and later life. For most of the world as recently as the first part of the 20th century, sex was taboo at midlife, and conversations about sex transpired behind closed doors. Today, unmarried or unpartnered people in midlife or later do not have to forgo dating for the rest of their lives like spinsters and confirmed bachelors of generations ago. The image of an older single man or woman as too old for sex, love, or marriage has been slowly changing and did so more dramatically when baby boomers came on the scene so that marriage, romance, and sex are now more central to their lives.

Baby boomers, named after the post–World War II increase in the birthrate, were born between 1946 and 1964 from parents who came of age during World War II. Baby boomers came of age in the 1960s and '70s and they changed social attitudes. Compared to past cohorts, more of them, as well as members of subsequent cohorts, may choose never to marry, but not for lack of romance. As divorce has become more widely accepted, divorced persons get back into the dating game. According to an AARP study of unmarried people in 2003, divorcees comprise 48 percent or almost half of singles between the ages of 40 and 69. The second-largest group is the proportion of never-married persons at 31 percent, while widowed persons comprise 13 percent, and those who are separated make up a smaller minority at 7 percent.

With more openness toward sex, people have come to recognize that having a sexual relationship is associated with better health. Results from two studies sponsored by AARP showed that those with a sexual relationship regarded their health and well-being as better than those who did not. Its latest sexuality study, conducted in 2004, showed that for more than half of a nationwide representation of married and unmarried people ages 45 and older, sexual activity is considered a critical part of a good relationship, and a satisfying sexual relationship is an important factor affecting their quality of life. A vast majority in the study, although agreeing that sex receives too much emphasis in today's culture, also have a positive attitude toward it. They do not agree that sex is for younger people only. They enjoy it, and 49 percent of those with sexual partners report having regular sex.

The 2004 AARP study also showed a substantial increase from 1999 in the percentage of adults seeking information about sex from various sources. There was a significant growth from 1999 to 2004 in the proportion of midlife and older adults who had sought treatment for a sexual functioning problem. Likewise, there was an increase in the use of medicines, hormones, or other treatments to improve sexual function in men.

Widows and widowers no longer need to embrace celibacy for the rest of their lives. There is greater acceptance by society of different forms of unions, and more opportunity for unmarried adults to live together without social sanctions. More persons with gay and lesbian sexual orientation are coming out into the open in midlife and later life as well. In fact, the chosen family for a gay or lesbian person at the end of life may comprise more friends than blood relatives.

Finally, midlife and older people today have more avenues to dating, courtship, and new relationships than in the past. The majority of women have careers and find mates in the office. Whereas just a few decades ago people met through family, friends, or church, today there are matchmaking and dating services for all ages, social networking Web sites, support groups a few keyboard clicks away on the Internet, and other electronic methods to find dating partners and mates. Midlifers can even search for their high school sweethearts on the Internet and revive old romances.

Indeed, the prominence of dating and courtship in midlife and later life has transformed midlife relationships in such an extraordinary way because of its novelty in the history of the human experience. In addition, the dating scene can very well be complex and varied because of the accumulation of many decades of experience and sexual relationships. Romantic relationships have the potential to be richer, fuller, multifaceted, deeper, more painful, more turbulent, and also more pleasurable. In addition, these relationships can comfort and relieve loneliness as people face their mortality.

Courtship and Dating

In midlife and later life, the lenses through which people see, feel, and experience romantic relationships are altered. Although youth have seemingly

unconstrained dreams, in midlife the dreams may remain but may also have been displaced by regrets, lost hopes, and lost loves. Although in youth, friends and parents may mostly influence romantic relationships, whereas in midlife and later life the presence of children, and sometimes ex-spouses and former in-laws, add to the dynamics of romance and falling in love again. People in their 20s and 30s look forward to children and having a family of their own, while in midlife people start thinking of their old age and mortality.

AARP, aiming to raise awareness of midlife and later life relationship issues, conducted a landmark study in 2003 on single people's lifestyles, dating, and romance. The results showed a facet of singles in midlife and later life that had hardly been seen in the past (see Figure 1). The majority, or 63 percent of singles ages 40 to 69, dated, either exclusively or nonexclusively. Seven percent of men and 3 percent of women reported having same-sex dating partners. Some singles did not date but were interested in dating and looking for dates; others would date if the opportunity came but did not actively seek dates. Among the study participants who were still interested in dating, those who did not date were apt to be women in their 60s and people who were passively waiting in case the right person just happened to come along. The smallest percentage comprises the group of singles that had lost interest in dating.

Figure 1 Dating Among Singles Ages 40 to 69

Among singles in midlife, dating does not necessarily lead to marriage. In fact, about a third of singles said they were not sure whether they should marry when or if they found themselves in a committed, exclusive relationship. Cohabitation was an option for many.

If people do not necessarily date to find a spouse or partner, why then do people date? As the AARP study showed, freedom feels good, but loneliness and lack of companionship make life difficult. About half of singles dated in order to have someone with whom to talk or do things. Dating to have fun was a lesser need.

Singles in midlife and later life said that an advantage to dating that they did not have while they were younger was the comfort that lies in the wisdom of age, maturity, and experience. Furthermore, they felt more carefree and had more freedom and independence. They also noted a lack of social pressure. The following quotes from single adults published in *Lifestyles, Dating and Romance: A Study of Midlife Singles* who were participating in focus groups illustrate these reactions:

“I feel more confident ‘in me.’ I’ve had more years to learn more lessons, and feel I’m a much better person now.”

“I am certainly older and wiser about the dating scene and what I definitely want in a partner.”

“When you’re young, you live to date or be in a relationship because society does such a good job of making you think you’re not complete unless you have a partner. When you mature emotionally, you realize that you are perfect unto thyself.”

In contrast, single persons also mentioned barriers to dating. These vary quite widely. Some cited difficulties meeting people due to their age, family, and time pressures; lack of desirable people to date; fear for their safety and of sexually transmitted diseases or AIDS; health problems or disabilities; and internal barriers such as problems with self-esteem, fear of rejection, or lack of trust.

Playing the field was not common among singles in general. Among those who dated, slightly less than half dated more than one person in a year, and slightly more than half dated one person only. The best sources of dates were meeting new people through friends, relatives, and coworkers, but singles organizations, matchmaking services, and online services are emerging avenues—as frequently mentioned as the church—for finding dates.

Singles in their 40s date more frequently than singles in their 60s. In general, however, spending a romantic evening with one’s partner or going on

a date occurred often for 1 in 10 singles and never for more than 3 in 10 singles, with women saying never more than men. Likewise, making love or never doing so corresponded with the frequency of spending a romantic evening or going on a date. To put this in perspective, about 6 in 10 singles reported often watching TV alone.

Gender Divide

The gender divide is markedly apparent in dating and courtship during midlife and later life. Women were more likely to date to have someone with whom to do things; while among men, sexual activity was a more important reason for dating. Although a small minority, 5 times as many men (11 percent) as women (2 percent) in the AARP study said that their major reason for dating was to fulfill their sexual needs. Furthermore, 1 in 10 men wanted to have sex on the first date, which was 10 times the rate for women (10 percent versus 1 percent). Indeed, single men were not too happy with the frequency of their sexual activity, while women were more likely to say that it was just right.

Of much interest is the fact that men tended to prefer and date women who were younger than they were. In contrast, at least a third of women, perhaps for a lack of older men or because they really meant it, said they wanted to date younger men.

Men and women were also clearly different in their characteristics, attitudes, and dating and courtship behaviors. Single men may be seen through four different personas. There are shy guys who are likely to be either widowed or never married, who are interested in dating but may not be trying to date or have given up trying because of shyness or problems finding a date. Their lack of self-confidence seems to keep them from meeting new people, making it more difficult to find women to date. These men may also be in poor health and not quite as optimistic about the future as others their age. Dreamers are likely to be looking hard for dates but not having much luck, partly because of their desire to date physically attractive women while at the same time meeting few potential partners. They do try to find dates more aggressively than the shy guys. Swashbucklers are likely to be active, healthy, confident men who like the single

life. They date more and have more sex than the shy guys and dreamers. They like to play the field, may have multiple relationships, and resist women who push for commitment. The fourth group of single men can be called the Romeos. They tend to be happy, optimistic, and self-confident like the swashbucklers but are more apt to be in a committed relationship. They engage in a lot of sexual activity and tend to have no dating problems.

Single women, on the other hand, fall into slightly different categories in their dating attitudes and behaviors. Passionate lovers are healthy and likely to be in good financial shape. They also tend to be romantically involved with someone, engaged in a lot of sexual activity, and likely to have few or no dating problems. Women in search of dates and sexual partnership comprise another group. These women are more likely to be divorced, active, healthy, and more affluent than the average single woman. Yet as their persona implies, their biggest frustrations are not knowing where to meet people or meeting too few people to date. The aspiring Cinderellas face many challenges, including poor health and finances. They tend to have a dimmer outlook on life and the future than other single women. Some may have suffered depression and have inactive lifestyles. Although some may have given up interest in dating, others want dates or want someone who will take care of them. The last type of female persona is the satisfied single, typically widowed and retired. Satisfied singles miss having someone around with whom to do things and want company. Nevertheless, they are content and are not necessarily and actively looking for dates. However, they are daters in waiting, open to dating if the right person comes along.

Conclusion

As the median age of the population increases and as people lead longer lives, the trend is toward more people dating and courting in midlife and the later years. Women dating younger men may be an increasing trend as well if women continue to live longer than men. Women and men can look younger, and perhaps more appealing as dating partners, longer now with better anti-aging cosmetics on the market and cosmetic surgery and other procedures readily available.

Although the AARP studies have uncovered important insights into midlife and later life dating and courtship, more research can provide a better understanding of other issues associated with such pairings, adding to knowledge not only about the people in the midst of it but also about the reactions of their children and other family members. Complications in family life can occur when a divorced or widowed parent or grandparent enters a dating relationship. Furthermore, new ways of meeting and dating people, with the advent of the Internet and online matchmaker Web sites as well as other developments of the 21st century, are becoming increasingly common, yet the implications, risks, and rewards of meeting dates that way are not yet fully known. Finally, an increase in HIV-infected people in midlife and later life is occurring because many daters do not consider themselves susceptible and do not use protective measures. Research on effective means of educating middle-aged and older adults about prevention of sexually transmitted diseases is a crucial research focus. In short, more and deeper inquiry is needed to delve into the pleasures of dating and courtship in midlife and later life and into the problematic issues these bring.

DATING RELATIONSHIPS IN ADOLESCENCE AND YOUNG ADULTHOOD

Although friendship and peer relations hold great importance for adolescents and young adults, dating experiences represent fundamentally new relationship terrain during this phase of life. This entry explores the character of early romantic relationships, focusing on what is known about factors influencing variations in the timing and characteristics of dating involvement, and some of the consequences of dating for understanding adolescents' and young adults' well-being and behavioral choices.

Definition

In earlier eras, courtship was highly structured and typically orchestrated and supervised by an adolescent or young adult's parents. In addition, the primary purpose of heterosexual socializing was to forge a bond that culminated in a marriage proposal. Contemporary dating relationships, in contrast, lack the heavily scripted and managed qualities of these earlier liaisons and especially in adolescence, frequently are not considered by young people as a gateway to an eventual marriage. Instead, dating relationships fill needs for companionship and fun, exploration of sexual feelings and the desire for intimacy, and even status enhancement. Yet research has also documented that adolescents and young adults accord much importance to their dating relationships, as over time romantic partners become an increasingly key source of positive and negative emotions, reference, and influence. Recognizing that dating does not necessarily connote participating in specific activities (dinner and a movie) or levels of involvement (going steady), however, a working definition some researchers use is simply when one likes someone and he or she likes that person back. This definition reflects that a degree of reciprocation is necessary; that is, absent this shared element, the young person can be considered to have a crush or unrequited love. This definition also distinguishes dating relationships from casual sexual contacts, where positive regard for the other is not prerequisite.

The Characteristics of Dating Relationships

A helpful way to describe the characteristics of early romantic relationships is to compare them to the same-gender friendships that are also an important feature of this phase of the life course. Whereas friendships are most often forged on the basis of similarity, romantic relationships more commonly bridge differences. In addition, young people have a backlog of experience in how to conduct a friendship relationship but almost by definition lack experience in the specifics of developing romantic ties. Accordingly, researchers have noted that while friendships are typically considered an arena of social support and comfort during this time, the dating world is more often a source of uncertainty and anxiety. For example, friendships are often characterized by high levels of intimate self-disclosure. In contrast, young people often experience awkwardness and a lack of confidence as they begin to develop romantic ties.

At the same time, romantic relationships often engender heightened emotionality that contrasts further with the more settled world of friendship. Dating relationships have the potential to include various forms of sexual intimacy and, more generally, to become a special attachment. These features of dating relations are far from inevitable, however, and average durations of early romantic ties support the young person's view that dating relationships are relatively more precarious. Even within the context of ongoing relationships, different interests are common and a source of further uncertainty and potential distress.

Another distinction is that, while young people can successfully navigate multiple friendships, issues of exclusivity and commitment loom larger in the world of romantic attachments. It is widely recognized that dating is a period for discovery and exploration; yet norms often discourage the practice of dating more than one person at a time. Research shows that a majority of young people believe that it is wrong to date more than one person, but statistics also reveal that flirting with someone else while dating a particular romantic partner and even seeing someone else are relatively common occurrences. The lack of specificity of dating relationships (i.e., one is not betrothed or married) and the many opportunities presented by contemporary youth culture undoubtedly contribute to

these patterns. Yet research has also shown that jealousy is quite common, and real or imagined infidelities are a major source of interpersonal conflict in dating relationships.

Sources of Variation in the Timing and Character of Dating Experiences

Adolescents and young adults vary considerably in the timing of their initial entry into the dating world and in the character of these experiences. Early physical maturation is associated with an earlier onset of dating for both male and female adolescents, and youths who are considered popular are also more likely to begin dating earlier relative to their less socially advantaged counterparts. Research has also shown that youths whose early relationships include cross-sex friendships are more likely to begin to date at an earlier age, and some family factors have also been linked to dating patterns. For example, a lack of parental supervision is associated with earlier dating, and the adolescent's more general risk profile (e.g., alcohol use) is also associated with earlier heterosexual involvement.

Consistent with the logic of attachment theories, the parent-child relationship is an important source of individual differences in the nature of romantic relationships. Researchers, however, have also explored other sources of variation, including factors such as age, gender, and race/ethnicity as influences on the qualities of dating experiences. Some researchers have depicted early dating relationships as relatively shallow and superficial, noting that some young people can be considered dating only because they have declared that they are a couple. In such instances, the two parties may never have been alone together or participated in any activities that would be considered a date in the more traditional sense. Researchers have also suggested that middle school or junior high age youths, due to their general lack of experience in this domain, may be reluctant to be themselves when they are with someone in whom they have a romantic interest, a withholding process that may inhibit the development of more mature forms of intimacy. Indeed, research has documented that older youths engage in higher levels of intimate self-disclosure with their romantic partners, are

more likely to rely on them for tangible and social support, and are somewhat less invested in the status implications of their dating choices. Developmental shifts also occur in basic patterns of socializing. Early relationships often involve interacting within the context of larger friendship groups, while later on romantic relationships become increasingly exclusive and dyadic. But while studies clearly show age trends in the direction of more complex and intimate relationships, some recent research highlights that even the earliest dating relationships are considered meaningful to the young people who participate in them. Thus, dating and romance are considered by most teens to be a major preoccupation and source of both positive and negative emotions.

The literature on early romantic relationships has long posited gender differences in the centrality of romantic ties and in the ways in which they are experienced. Adding to the general notion that girls and women are fundamentally more relationally oriented relative to their male counterparts, Eleanor Maccoby focused attention on gender differences in the nature of the friendship experiences that typically precede the process of crossing over into heterosexual territory. Maccoby argued that girls often develop close dyadic friendships and learn cooperative ways of relating to one another that contrast with boys' styles of play and friendship. This author suggests that the emphasis on competition and the one-up style of discourse common in many male friendship groups influences the nature of romantic ties, as males tend to transport their dominant interaction style into these new relationships. This potentially influences the dynamics within dating relationships, as it contributes to inequalities of power and may be associated with increases in girls' depression. A related theme is that boys are frequently socialized by other males to focus more on sexual conquest than on relationships and the development of intimacy.

Although these broad patterns have received empirical support, particularly in ethnographic studies, some analyses of survey data do not accord entirely with this portrait of gender differences. For example, in a recent study of adolescent respondents, boys reported less confidence and more awkwardness or reticence in communication with their romantic partner and scored lower on perceived power in the relationship; no significant

differences were observed in responses to questions indexing feelings of love for the partner. Studies focused on samples of young adults have noted similar results. Several studies of university students have shown that most romantic relationships, whether based on self-reports or researcher observations, would be characterized as egalitarian, followed in frequency by a power balance that favored the female partner. In addition, these studies of college populations do not typically find large disparities by gender in reports of passionate love for romantic partners. Some researchers have noted that specific subgroups of males do fit the profile of disinterested players, but it is important to highlight that this does not characterize the relationship experiences of a majority of adolescent boys and young men.

Fewer studies have explored the role of other social characteristics such as socioeconomic status and race/ethnicity on the nature of adolescent dating relationships, but some theorists have posited differences and a small number of studies have been conducted. Some researchers have suggested that, since lower status youths are less likely to succeed in the educational and later on in the occupational arenas, they may invest more heavily in their interpersonal relationships. According to this logic, the romantic relationships of disadvantaged youths should, on average, be more intense and long lasting than those of more advantaged youths who typically have more diversified interests and a greater focus on long-term goals. An alternative perspective is that peer norms in disadvantaged communities tend to foster a player lifestyle, where individuals gain the status they may be denied in the larger society by accruing a large number of sexual partners. In addition, the lack of meaningful employment available for those living in disadvantaged areas may deter adolescents and young adults from considering dating relationships as a realistic gateway to a stable, economically viable partnership (i.e., marriage relationship). Elijah Anderson and other researchers have observed these attitudes in the inner city areas they have studied, although some survey data show that this player world view is far from ubiquitous, even in disadvantaged areas. Other analyses reveal that the average durations of dating relationships of African-American and White adolescents are generally similar, and reports of feelings of love for the

partner do not differ significantly across these subgroups. These studies document, however, that African-American youths report spending somewhat lower amounts of time with partners and lower levels of intimate self-disclosure to them. These findings accord with other studies that have focused on how adolescents spend their time. For example, researchers have documented that African-American youth relative to their White counterparts on average report less time interacting with friends and more time with family members. Differences by race/ethnicity have also been noted in parental supervision and other parenting practices; thus, it is useful to consider other social relationships in which youths are embedded as a way to understand more about patterns of dating associated with race/ethnicity or other cultural differences. More research is also needed on the qualities of romantic ties of youths from Hispanic, Asian, and other race/ethnic groups, as African-American teens have been more often the subject of empirical investigations.

Consequences of Dating Involvement

Early research on the consequences of dating often centered on negative aspects of these experiences. For example, several studies showed that early dating, particularly dating an older male, was associated with girls' greater involvement in delinquency and more trouble in school. Another researcher found that early maturing girls who dated had lower self-esteem than their less developed, socially advanced counterparts. Also fostering a generally negative portrait, studies often show that early dating is correlated with other risky behaviors such as alcohol and drug use. Finally, entry into the dating world is associated with greater odds of becoming sexually active, findings that also fit into a problem perspective on dating involvement.

More recent research on the consequences of dating for adolescent and young adult well-being and behavior presents a more complex picture. One of the limitations of early studies is that researchers often presented a simple contrast of daters with nondaters or focused on early age of dating involvement. Contemporary research has increasingly given attention to qualities of the relationships

formed, characteristics of the romantic partner, and other qualifiers of effects of dating experiences. For example, starting to date has been linked with increases in adolescent depression, particularly for girls; yet research has shown that these changes are often linked with increased conflict with parents, dynamics that actually explain much of the dating-depression link. Researchers have also begun to explore specific qualities and dynamics of relationships that may be associated with positive or negative consequences for the individual. Breaking up, cheating and lack of trust, and relationship violence are dynamics that have been linked with emotional distress, but researchers have also shown that romantic involvement is associated with positive emotions and feelings of social competence. One study, for example, documented that romantic partners were reported as a source of positive emotions more often than was the case for parents or same-gender friends.

Research on the connections between dating and delinquency involvement has also progressed beyond the dating–nondating distinction. Relying on information gleaned from adolescents as well as from their romantic partners, researchers showed that the partner’s level of delinquency involvement was significantly related to teens’ own reported involvement, even after traditional predictors such as the delinquency of friends and parenting practices were taken into account. Studies of effects of dating on academic achievement have documented similar findings, in that the romantic partner’s grades were found to be a significant predictor of an adolescent’s own grades. In the latter study, effects were observed for male and female participants, but the association was stronger for male adolescents. This line of research indicates that the particular attitudes and behaviors of the romantic partner need to be taken into account, as researchers move toward a more comprehensive understanding of the consequences of dating experiences.

Another important line of inquiry that has provided a new perspective on dating consequences is focused on sexual behaviors. Although media treatments have frequently decried the end of formal dating and suggested that teens and young adults prefer casual hook-ups to committed relationships, social science research documents that most adolescent and young adult sexual activity takes place within a dating context. Such basics of

romantic relationships as duration of the relationship are reliable predictors of the odds of becoming sexually intimate with a given partner, and research shows that specific qualities such as feelings of love and levels of intimate self-disclosure are also associated with greater odds of having sexual intercourse. This research is potentially important because it shows how relationship experiences generally considered positive from a developmental standpoint may be associated with outcomes that have typically been understood as risky or problematic. This suggests the utility of including relationship-based programming for teens as a key element of prevention and intervention efforts. It is also important to note that these studies of relationship context have shown that positive relationship qualities were significant predictors of male as well as female sexual behavior. This provides some support for the notion that aspects of the gender divide (i.e., boys want sex, girls want romance) may be somewhat overstated.

New Directions in Research on Dating

Most of the studies described above have focused on a current or most recent dating relationship or in earlier research, on a single aspect of dating such as the age when teens begin to date. Yet researchers recognize that a number of different relationships are typically formed across the period of adolescence and young adulthood. Thus, there is increased interest in capturing trends or overall styles of dating that better reflect the whole of the young person’s romantic and sexual experiences. This is particularly important as researchers seek to link features of early dating to later adult outcomes, including the likelihood, stability, and quality of marriage and cohabiting relationships. Currently, research on adolescent and young adult relationships coexist as rather separate literatures, but longitudinal studies provide the opportunity to examine life course continuity as well as change in the character of intimate attachments. This research can also examine developmental shifts in the relative salience of parents, peers, and romantic partners as respondents mature into adulthood. Research on the dating patterns of mature adults is also a logical next step, as romantic involvement for many becomes less routinely viewed as a pathway into marriage relationships.

More focused studies of underresearched groups are also needed, including additional research on the romantic experiences of Hispanic and Asian youth. Some research on gay, lesbian, and bisexual teens' experiences has been conducted, but more emphasis has been placed on early sexual rather than on romantic relationship experiences. Researchers have pointed out that due to feelings of stigma and fear of social exclusion, teens may have greater difficulty developing and maintaining romantic ties. Traditional high school settings may also limit the adolescent's exposure to potential partners. A number of studies have focused on depression levels, suicide ideation, and substance use among gay teens, but as in the study of heterosexual involvement, more research is needed on variations in the character and effects of their romantic and sexual experiences.

DECEPTION AND LYING

In the United States, deception and lying are widely condemned but widely practiced in all types of human relationships. The nature of a relationship affects and is affected by the frequency of deception, the motivation for deception, the subject matter of the deception, the interactive manifestations of the deception process, the awareness of and desire to detect deception, the accuracy of that detection, the methods used to detect deception, and the consequences of the deception.

The terms deception and lying are often used interchangeably, but deception is normally considered a broader term, encompassing many tricky and misleading behaviors, including lying. Attributions about the existence of a lie, whether it is good or bad, and to what extent it should be sanctioned are most often based on perceptions of (a) the communicator's intentions and/or motives, (b) the normative expectations for communication in the situation, and (c) the consequences resulting from the communicator's behavior. This entry discusses how lies are studied, why people lie, lies that may initiate and sustain relationships, lie detection, and the relational consequences that accrue from lying.

Studying Lies

In order to systematically study liar behavior, lie detector behavior, and the effects of lies, researchers generate lies in various ways. Videotaping people lying or telling the truth about their identity or their attitudes is the most common method of studying low-stakes lies. High-stakes lies, where success or failure of the lie is associated with major consequences, are often derived from cheating or stealing formats. For example, research participants are given an opportunity to take \$50 from a wallet in an isolated room. If they take the money and fool an interviewer by lying about it, they can keep it. If the interviewer catches them in a lie, they are told they will have to sit in a small, dark, and cold room for 2 hours with periodic bursts of high decibel sounds, although no one receives the punishment. The videotapes of these liars have been helpful in generating knowledge, but there are other aspects of relationship lies that are not accounted for with these methods.

For example, individual liar behavior does not help researchers understand how relationship partners jointly construct lies—through an implicit or explicit collaboration. In addition, laboratory-induced lies are limited to a single encounter, whereas family, work, and intimate relationships provide repeated opportunities to interact—providing both the liar and lie detector with additional opportunities to accomplish their goal. Many lies in close relationships do not even involve false accounts; they use secrets and silences in order to create a false reality for their partner. Covert lies (self-deception) and lies designed to benefit one's partner are also types of relationship lies in need of further study.

Motivation for Lying

Lies occur for a variety of reasons, but the most commonly cited motive is to avoid punishment or to protect oneself from harm. Other reasons include trying to obtain something rewarding, to protect or help another person, to win admiration from others, to get out of an awkward or embarrassing social situation, to maintain privacy, to exercise power over others, to fulfill social expectations, or to have fun.

Lying and the Initiation of Relationships

Outside of any particular relationship context, men and women rate trustworthiness and honesty as more desirable partner characteristics for both short- and long-term romantic relationships than an exciting personality, good health, adaptability, dependability, sense of humor, kindness, and understanding. Despite surveys that extol the desirability of honesty, certain situational exigencies can easily lead to dishonest behavior. Being honest, for example, may be deemed less important than some other relationship goal such as building the self-esteem of one's partner, maintaining loyalty to a friend, or massaging truths that might hurt a loved one.

During the get-acquainted stage of relationship development, low-stakes lies are reportedly common. Each person is trying to present himself or herself in the best possible way. When research participants in one study were instructed to appear competent and likable when talking to a new person, they lied twice as much as those who were simply told to engage in a get-acquainted conversation. Both men and women say they would be willing to lie about their intelligence, personal appearance, personality traits, income, past relationship outcomes, and career skills to a prospective date who had a highly attractive face. For undesirable partners even names and addresses may not be accurately conveyed. Both men and women are willing to tell lies about their sexual history or a relationship competitor. Men often exaggerate their sexual experience with male friends, and women are likely to report fewer past sexual partners to a person who has long-term relationship potential. When one gender greatly outnumbers the other in a dating environment, the more plentiful gender is expected to tell more lies.

Lying in Close Relationships

Part of the reason close relationships are close is that each partner expects the other will protect rather than exploit their individual vulnerabilities and their relationship. Their emotional closeness generally acts as an inhibitor to wholly self-oriented lies. Thus, when perceptions of dishonesty in a close relationship increase, the perceiver's

relationship satisfaction and commitment is likely to decrease. Although they are not common, self-serving lies do exist in close relationships, and they often violate its core expectations so that their effects can be devastating.

The more common lies in close relationships are those told to support one's partner, to conceal negative feelings about one's partner, and those directed at outsiders for the benefit of the relationship. Lies that support, protect, and sustain their partners may mean such things as telling them what they want to hear, building and maintaining their self-esteem, or helping them accomplish their goals. Making claims about a partner's virtues is another form of deception if the claimant does not believe his or her partner actually has those virtues.

Detecting Lies

Accurately detecting the lies of strangers by observing their verbal and nonverbal behavior is usually reported to be just above chance (50 percent)—an average across studies of about 54 percent. Even this rate of lie detection, which is the result of averaging across truthful and deceptive messages, is inflated by the fact that people are far more accurate in identifying truthful messages than lies, thereby making the accurate detection of lies alone lower than chance. The closeness of a relationship can lead to greater accuracy or greater inaccuracy in detecting lies.

People expect their lies to be detected more often by people who know them well, and they often are. They expect it because they expect people in close relationships to be so familiar with their typical behavior that any deviations from that will be noticed and there is some evidence to support this belief. When suspicion of deceptive behavior is coupled with behavioral familiarity in close relationships, accuracy in detecting deception can also increase. But suspicion can be problematic if the suspected liar is not lying and resents the distrust that his or her partner's suspicion illustrates. Suspicion can also create more suspicion to the point where neither person trusts the other. Suspicious behavior also has a tendency to put the suspect on guard—possibly leading him or her to spend more time and energy covering up clues and creating new lies.

Since serious lies are not expected in close relationships (there is a strong truth bias), liars may not initially be scrutinized carefully. Familiarity with behavioral routines can also be an advantage to the liar. Liars in close relationships know a lot of the same information that the lie detectors know and will use that familiarity for their own ends during the lie and lie detection process. Accuracy research to date is largely based on detached observers judging monologues of other speakers, but accuracy may be impeded in actual, ongoing close relationships because the detector is actively interacting with the liar while trying to assess his or her truthfulness. Perhaps the single biggest contributor to decreased accuracy in lie detection in close relationships occurs when a detector puts a higher value on the need to maintain relationship closeness than the need to uncover a lie. People in close relationships are certainly not averse to practicing motivated inaccuracy when faced with partner behavior that poses a threat to their relationship. In fact, relationship partners who tend to seek relationship threatening information are also less trusting, more suspicious, and more likely to terminate their relationships.

Detecting lies by observing the behavior of one's partner has been the predominant research paradigm to date, but other research indicates the two most common methods for uncovering lies in everyday relationships are (1) getting information from a third party and (2) finding physical evidence that contradicts the liar's story.

Relational Consequences

Both deception and truth telling can result in positive or negative consequences. Disclosure of truths or the keeping of secrets can contribute to marital satisfaction and closeness or detract from it. It all depends on how, why, when, and where it is done. What one views as the consequences of lying and deception in close relationships depends on what type of lie is in question (altruistic vs. self-interest), what is being lied about (an affair vs. a false compliment), and when the judgment is made (upon discovery vs. much later), as well as other factors. The assessed consequences of close relationship lies will also vary depending on who is making the assessment. Liars often view their

own behavior as far less harmful, offensive, and consequential than the target of the lie. Liars often describe extenuating circumstances that they view as justification for their lies, but targets often do not share those views.

Even though most of the consequences of deception in close relationships are examined in the context of discovered or revealed lies, there are lies that go undetected. To the extent that the lie or lies told have powerful effects on the liar (e.g., guilt, anger, fear, embarrassment), these effects may manifest themselves in almost any dialogue with the liar's partner. Without a satisfactory explanation of these emotions, they can become just as divisive a force to the relationship as the lie itself.

Lies told to cover a major relationship transgression and lies that betray the bonds of closeness are capable of creating a wide variety of negative consequences for the relationship and its participants—for example, hurt feelings, lowered self-esteem, confusion, suspicion, or a desire for revenge on the part of the lie's target; a loss of trust, respect, and/or credibility for the liar; and a lowered level of satisfaction and/or commitment to the relationship.

Current research does not tell researchers a great deal about how partners to a relationship renegotiate closeness following a lie that has been detected and seriously threatens their relationship. Factors that may work to the advantage of couples who cope effectively with a potentially harmful relationship lie (or lies) include (a) a history of the liar doing many things with positive intentions and in the best interests of the relationship; (b) a plea from the liar for forgiveness and repeatedly demonstrating his or her commitment to rebuilding relational closeness; (c) a situation in which the discovery of the lie opened up issues for the couple that needed to be discussed for the survival and welfare of the relationship; (d) a situation in which the lie, by bringing the relationship to the edge of disaster, reminded both partners how much they wanted to save the relationship; and/or (e) a situation in which the process of mutually solving the problem or problems created by the lie served to reestablish and strengthen relationship bonds.

DEPENDENCE

From the moment of birth, individuals depend on others. Dependence in human relationships refers to how much one relies on another person to obtain the highest possible level of rewarding and desirable things and to avoid undesirable and costly things—that is, to obtain the best possible outcomes. Dependence on a particular other increases to the extent that an individual's needs cannot be satisfied by a different person. Just as one country might be dependent on a particular country to fulfill its need for oil—the arrangement with that particular country is better than with any other country—so too might one person depend on a relationship partner to fulfill important relationship needs that are better satisfied in that relationship than in others. As such, an individual's

dependence on another person is an indicator of how much the other person directly influences the quality of the individual's experiences.

This entry examines dependence in the context of ongoing relationships, with a particular focus on romantic relationships. Dependence on relationship partners is compared against relationship satisfaction and relationship commitment, a distinction is made between voluntary and nonvoluntary dependence, and the general meaning of dependence used in this entry is distinguished from outcome dependence.

Relationship Dependence Versus Other Relationship Characteristics

People strive for gratifying and lasting human relationships. Whether relationships are satisfying and enduring rests on how individuals see their relationship and particularly on the standards of comparison they adopt.

When it comes to gauging whether a relationship is satisfying, it is common to compare the current relationship with past ones, relationships of close others, or any relationships that are salient in shaping one's ideas of what one might expect in a relationship. In short, one indirectly or directly considers what one deserves, which is referred to as one's comparison level. A relationship that meets or exceeds expectations is satisfying; one that falls short of expectations is dissatisfying. Moreover, the same relationship may go through different phases, with changes and shifts over time in satisfaction. For example, as two individuals begin dating, they may feel happy with the way things are going. One individual may reflect on the fact that his or her partner is more kind, witty, and trustworthy than others he or she has dated; the other may appreciate having a partner who is more thoughtful and physically attractive than what might have been expected. Alternatively, each may acknowledge feeling satisfied without giving much thought as to why. As their commitment deepens and they grow increasingly accustomed to each other, their feelings may ebb and flow. At times, minor personal idiosyncrasies may become annoyances, and the lack of novelty may trigger some boredom; at other times, knowing that each puts the other first and trusts the other to do the same brings about peace of mind and feelings of fulfillment.

In contrast to judging whether a relationship is satisfying, when it comes to gauging how much one needs a relationship (i.e., how dependent one is), individuals more often consider how the current relationship compares against the situation they would likely be in if they were not in the current relationship—either being in an alternate relationship or being alone. The alternative situation used in comparison has been referred to as the comparison level for alternatives. A person is likely to leave the current relationship (or change the current state of the relationship) if it is anticipated that an alternative arrangement would yield higher well-being in the long run—that is, higher outcomes over time than obtained in the current relationship.

As such, dependence is strongly related to being committed to a relationship: Both refer to a strong inclination to continue a relationship. They differ in how the terms are commonly used: Whereas dependence is more commonly used to indicate an objectively defined state in which a person needs to remain in a relationship, commitment is more commonly used to indicate a person's subjective feelings that favor remaining in a relationship, feelings that may reflect lacking alternative situations, being satisfied, and other considerations (e.g., friends, children, past memories, future plans, shared property and tangible objects, all of which are worse off or altogether gone in alternative situations).

Dependence defined as needing a relationship differs from the sense of dependence that implies personal feelings of inadequacy, an inability to be independent from and assertive with others, and consequently, a need to rely on others because of personal limitations (i.e., symptoms of a person diagnosed with dependent personality disorder). One difference between these two senses of dependence is in the pervasiveness of the need to rely on others. Relationship dependence typically refers to relying on a particular relationship to fulfill certain needs vis-à-vis any relationship—that is, it involves relying on a particular partner because something works particularly well in the given relationship. By contrast, individuals with dependent personalities exhibit an exaggerated reliance on others in all of their romantic (or other close) relationships. More importantly, individuals with dependent personalities rely on others to cope with perceived or real personal inadequacies, thus making their dependence reflect an undesirable trait. Relationship

dependence, by contrast, reflects a person's willingness to risk being vulnerable by relying on another, vulnerability which often is met by dependence and commitment on the part of the partner and has the desirable effect of creating a highly and mutually committed relationship.

Voluntary Versus Nonvoluntary Dependence

Although gratifying and lasting human relationships are desirable, the combination of gratifying and lasting is not always easily achieved. Some relationships indeed do last by virtue of being satisfying, for the most part. Voluntary dependence occurs when partners are happy in their dependent state; there may be several factors keeping them in the relationship, but ultimately they want to be with each other. In contrast, nonvoluntary dependence occurs when partners feel or are forced to remain in a highly dissatisfying relationship; although costs in the current relationship may be high in light of what one typically would expect to experience (i.e., one's comparison level), costs associated with leaving the relationship are even higher. For example, individuals who are not financially independent and must rely on a highly abusive partner for their livelihood likely experience a combination of high dependence and low satisfaction. If or when alternatives to the current relationship become viable, abuse victims take steps to leave their abusive partner so long as they feel sufficiently emotionally detached from the relationship.

Nonvoluntary dependence may characterize many different types of relationships, not just those in which a person is financially dependent. An individual may have few alternatives in meeting different types of needs and thus may have to tolerate lower outcomes to satisfy those needs. For example, given gender differences in life expectancies, the pool of potential male partners shrinks more than the pool of female partners. This difference creates a greater risk for nonvoluntary dependence among those seeking elderly men; feeling an acute need for companionship may cause one to endure annoying habits or other undesirable partner characteristics (i.e., partner characteristics that make outcomes fall below one's comparison level) in light of a lack of alternatives. Another example concerns efforts to

fulfill sexual needs in a social setting that has high rates of sexually transmitted diseases; to the extent that a person puts a higher premium on having a safe sexual partner than on fulfilling other needs that create satisfying relationships (e.g., a need to feel loved and well regarded), this person may come to feel stuck in a dissatisfying relationship.

Outcome Dependence

The term dependence, specifically outcome dependence, has also been used to characterize the association between any two people—even strangers—who find themselves in an interaction in which they affect each other's outcomes. Each is said to be dependent to the extent that he or she relies on the interaction partner for desired outcomes in a specific situation. In situations involving no dependence, a person does not rely on the interaction partner in any way for desired outcomes (independence); in situations reflecting dependence, a person's desired outcome is influenced either solely by the partner's actions (referred to as fate control), or by the ability of the person and partner to combine their actions in desirable ways (referred to as behavior control).

There are a myriad of situations in which one's immediate outcomes are fully at the mercy of another person (i.e., high fate control as the basis of dependence), such as watching a fellow basketball team player score points while one is sitting on the bench or having a business partner attract new business in a sector other than one's own. There are also situations in which one's immediate outcomes are partly at the mercy of another but require coordinated action with the other (i.e., high behavior control as the basis of dependence), such as relying on a basketball team player to pass the ball for an alley-oop score or having a business partner deliver part of a joint presentation to potential clients. Situations of outcome dependence also differ in other characteristics, such as whether there is a lot at stake in the situation (high dependence) or very little at stake (low dependence) and whether both partners are equally or unequally affected—the partner affected more has more to lose and thus has less power.

Is outcome dependence (having outcomes that are affected by a partner's actions) different from

the type of dependence described above (relying on a partner to fulfill important needs)? Both senses of the word *dependence* refer to having one's own well-being yoked to another person's actions. The two senses of dependence differ, however, in time frame. The term outcome dependence is commonly used to indicate being affected by another's behavior in a particular interaction; as such, it is used to characterize a given interaction situation. More general dependence refers more broadly to being affected by another's behaviors over repeated interactions; as such, it is used to characterize an ongoing relationship. The two senses of dependence also differ in that outcome dependence can be used to characterize an interaction situation between two people who have never met and who will go their separate ways after their interaction (e.g., on a flight, being affected by the person seated in the adjacent seat), whereas general dependence would not be used to characterize an association between strangers.

Despite these differences in the use of the word dependence, the core theoretical idea of dependence is the state in which one person's well-being is partly or fully at the mercy of another person. Importantly, people often act differently toward an interaction partner when they know they will interact with that person in the future. Specifically, people try to act in ways that further the type of relationship they want to have in the future with that person. In this way, specific interactions become linked to more general impressions that drive future interactions; the rewards or costs incurred as a result of a partner's behavior in a specific interaction inform more general impressions of how much one will rely on the partner for one's future well-being.

DEPENDENCY PARADOX

It is generally believed that yielding to expressions of dependence creates more dependence and less self-sufficiency. In fact, in many Western cultures, dependence on others is viewed as a sign of weakness and something that should be discouraged. However, recent research supports an alternative view of dependence on others, which is termed the *dependency paradox*. According to this view, true independence and self-sufficiency emerges because of an individual's ability to depend on close relationship partners in times of need: Relationships are critical in the lives of human beings, everyone must depend on others in certain circumstances to function optimally, and the degree to which this need is accepted by relationship partners reduces the frequency of this need. The following entry reviews theory and evidence for the dependency paradox.

Theory

The dependency paradox states that reliance and dependence on significant others is important for optimal functioning because it gives people the confidence they need to pursue personal goals, engage in independent exploration, and take on challenging activities. These behaviors, in turn, contribute to learning, discovery, increases in competency and self-esteem, and personal growth. The dependency paradox was extrapolated from Attachment Theory, which emphasizes the critical importance of relationships across the life span and asserts that attachment behavior (reliance on significant others)

should not be discouraged but instead should be accepted as an intrinsic part of human nature and acknowledged for its role in promoting optimal human functioning. A major proposition of this theory is that throughout the life span the perceived availability of a responsive attachment figure (also called a caregiver or relationship partner) remains the source of feeling secure—and only when a person is feeling secure will he or she be able to explore most effectively, confidently, and autonomously. Perceived availability is important because responsive attachment figures are internalized as available, and this internalization allows one to move forward without repeatedly checking on the attachment figure's availability.

The dependency paradox emerges from Attachment Theory and indicates that an attachment figure's (or relationship partner's) acceptance of dependence creates less rather than more dependence. Contrary to popular opinion, individuals who are not accepting of dependence are most likely to foster anxious dependence in their relationship partners. The logic behind this idea is that it is much easier for people to engage in behaviors that will enhance their personal growth (e.g., accepting challenges, exploring, trying new things, and taking risks) when they know someone is available for comfort and assistance if things go wrong. This is because an individual who feels confident in the availability and accessibility of his or her secure base does not have to cling to that base as much as an individual who lacks such confidence. Just as a driver without an insurance policy may be reluctant to drive long distances or take unnecessary risks because of the heavy price if something were to go wrong, so too are individuals reluctant to take independent excursions away from a relationship partner who does not provide good coverage in the case of an emergency. In this sense, the ready availability and accessibility of a relationship partner is necessary for optimal functioning.

Note About Overdependence and Underdependence

The dependency paradox views dependency as adaptive when it occurs because there is a need for it (e.g., because an individual is distressed and/or in need of support). Dependency that occurs in the

absence of need may be viewed as overdependence. A complete lack of dependence on others (even in times of need) may be viewed as underdependence and has been called compulsive self-reliance. Theoretically, both overdependence and underdependence result from having attachment figures (or relationship partners) who are not accepting of dependence and who do not consistently provide sensitive-responsive support when needed. Overdependence represents a means of clinging to a person whose availability and acceptance is uncertain, whereas underdependence (compulsive self-reliance) represents a means of coping with a relationship history in which attachment figures have been consistently unresponsive and unaccepting of dependency needs. These strategies may be based in one's relationship history (and carried forward into new relationships where they are no longer adaptive), or they may arise from experiences in current relationships.

Evidence

Evidence for the dependency paradox has been found for children and adults. With regard to children, by end of the first year, mothers who attended promptly to their crying babies had babies who cried much less than the babies of mothers who let them cry. Evidence also indicates that children raised by responsive attachment figures (e.g., tuned in to the child's signals, interpret them correctly, and respond promptly and appropriately) are able to explore in a confident way because they know whom to seek out in times of need. In contrast, children raised by attachment figures who are less sensitive and responsive (e.g., fail to notice the child's signals, misinterpret signals when they are noticed, and respond tardily, inappropriately, or not at all) show signs of restricted exploration because they are less confident about receiving care when needed. Similarly, for adolescents, researchers have found that independence is most easily established not at the expense of attachment relationships with parents but against a backdrop of secure relationships with them.

As for adults, the dependency paradox has been tested in samples of married and dating couples using surveys that ask couple members to provide reports of each other's behaviors, videotaped

observations of couple members' behaviors during discussion and exploration activities, and longitudinal methods that follow couples over time. These studies examine one couple member's independent goal striving as a function of the other couple member's dependency acceptance. Collectively, this research provides strong empirical support for the paradoxical hypothesis that accepting dependence promotes independence. Specifically, reports of one partner's dependency acceptance (defined as responsiveness to the other's needs and sensitivity to the other's distress cues) was associated with reports of the other's perceived independence and self-efficacy, engagement in independent exploration, and ability to achieve independent goals. Also, during couples' discussions of personal goals for the future, one partner's dependency acceptance (communication of future availability and sensitive-responsive support provision) was associated with the other's autonomous functioning (e.g., confident exploration of independent goals). Additionally, individuals whose partners were accepting of dependence (as observed and reported at one point in time) experienced increases in independent functioning over 6 months, and they were more likely to have accomplished an important independent goal that had been identified 6 months earlier.

Applications

Because research on the dependency paradox indicates that individuals are able to engage in more activities, accomplish more goals, use their minds better, and function more autonomously when their dependency needs are supported, this knowledge can be applied in a broad range of domains to optimize the functioning and to promote the well-being of individuals and families. This knowledge may not only enhance relationships by making people more mindful of the impact of their behavior on others, but it may also be of great use to therapists, counselors, clinicians, and schools and businesses as they strive to increase the functioning of clients, students, and employees.

DEPRESSION AND RELATIONSHIPS

Depression is a pervasive psychosocial problem that is a constellation of cognitive (e.g., difficulty concentrating), vegetative (e.g., loss of appetite), and affective (e.g., sad mood) symptoms. About 10 to 15 percent of the population will experience an episode of clinical depression at some point in their lives, and far more will suffer from subclinical levels of depression. There are many different causes and consequences of depression. Among these, social relationships appear to play an important role in the etiology, maintenance, and consequences of depression. This entry discusses interpersonal relationship problems that appear to be particularly problematic for people with depression and then explains some of the different reasons for these problems.

Relationship Problems and Depression

Scientists have identified numerous relationships that appear to be problematic for depressed people. For example, many people who are clinically depressed also experience marital distress. The marriages of people with depression tend to be laden with conflict, negatively toned communications, low levels of responsiveness, and difficulties with intimacy. Some married couples experience coercive processes in which one spouse's display of depressive behaviors, such as crying or making self-derogatory statements, is rewarded by the

other spouse who shows higher than normal levels of kindness, reduces demands, or temporarily stops hostile behaviors. In such couples, the relationship can actually maintain depressive behaviors, despite their otherwise negative effect on both spouses, because kindness and sympathy from the partner serve as a form of positive reinforcement and cessation of hostility, and demands from the partner can function as negative reinforcement. Both of these processes can prompt further depressive displays and cause frustration from a partner who inadvertently rewards the very depressive behavior that he or she would like to put an end to. There is some evidence to suggest that the quality of one's interpersonal relationships is more strongly associated with depression among women compared to men. However, the vast majority of the interpersonal processes outlined in this entry do not vary extensively as a function of sex—all are corrosive to the psychological well-being of women or men.

There are several reasons why the marriages of people with depression are marred by distress and dissatisfaction. First, the assortative mating effect happens when depressed people seek out other people with depression with whom to form a relationship. The amalgamation of two people's troubles and difficulties rarely forms the basis for a happy and contented relationship. Second, the shared stress effect occurs when the events that make one spouse depressed (e.g., loss of a job) also negatively affect the other spouse. Third, young people who are depressed sometimes exhibit truncated mate selection. The experience of depression appears to cause people to make hasty decisions to marry and to do so at a younger age. It is believed that this happens because young people with depression might see marriage as a way out of the difficult circumstances in which they otherwise find themselves. By marrying early, the mate selection process by which people carefully choose a potential partner is drastically shortened. This greatly increases the probability of later finding oneself in a distressed marriage.

Another relational context that appears to be disrupted by depression is that of a parent. Although much of the research on parenting and depression has focused on mothers, there is sufficient evidence to conclude that the experience of depression disrupts parenting by both mothers and fathers.

Parents with depression often have problems effectively relating to their children. For example, they tend to be less responsive to their children while interacting with them, exhibit fewer positive social behaviors, and complain to their children about their own problems as well as their child's behavior more than nondepressed parents do. These disrupted parenting behaviors appear to have negative consequences for children. The children of depressed parents show signs of rejection and agitation, even during infancy. They make less eye contact with their parent, express more negative emotion, and are less content than children who are with nondepressed parents. Parents afflicted with depression are 4 times more likely to have children who are depressed than are parents who are not depressed. This increased risk for depression among the offspring of depressed parents is the result of both genetic and environmental factors. The environmental factors include those disrupted parenting and social behaviors mentioned previously that apparently have depressogenic (i.e., depression inducing) effects on children.

Parental depression is clearly associated with remarkable problems in the parent-child relationship. However, it is also the case that people who are depressed often have a history of troubled relationships with their parents. Problematic experiences in the family of origin can reliably increase the risk for experiencing depression as a child while living in the family of origin, later in life as an adult, or both. These pathogenic experiences are generally the expression of maladaptive parenting. Adults who are currently depressed tend to describe their family of origin as rejecting, uncaring, and mired in conflicts. One family relationship dynamic that appears highly corrosive in terms of increasing risk for subsequent depression in offspring has been characterized as affectionless control. This occurs when parents are overly involved in and controlling of their children while at the same time express low care and concern for the child. The combination of parental overprotectiveness and low care seems paradoxical and creates emotional problems for the child. In such instances, the overprotectiveness of the parent appears to be motivated by concerns other than the child's actual welfare, such as the unfounded fears of the parent or projection of the parent's needs and concerns onto the child.

Child maltreatment can significantly predispose children to depression. Maltreatment in the form of neglect, physical abuse, or sexual abuse makes children about 4 times more likely to experience depression compared to those having no exposure to these noxious family experiences. Sometimes this depression is evident immediately while the child is still living in the family of origin. In other cases, the depression might appear later in life as the child progresses, or attempts to progress, to more advanced developmental stages of life (e.g., developing romantic relationships).

Other depressogenic family of origin patterns include unrealistically high parental expectations, extremely high or low family cohesion, low levels of social support from family members, and parental rejection. All of these family processes have been linked with increased levels of depression among the offspring from such families. It is important to note that the parent who might create an aversive environment for the child through these problematic behaviors is often the same parent who is passing on his or her genes to the child. Consequently, at least some of the psychological problems experienced by children exposed to maladaptive parenting could be the result of inheritance of genes that predispose the child to depression.

Relationship problems for depressed people are not confined to just the family context. Depressed people also have difficulties over the much larger domain of their personal relationships, including, for example, dating partners, friends, and roommates. One of the more common problems for people with depression is simply the lack of such relationships. People who have experienced depression over long periods of their lives will often lack many of the personal relationships that nondepressed people sometimes have in abundance. This is particularly unfortunate as the lack of a confidant is an important risk factor for depression. It is not necessarily the case that people need to have a high quantity of personal relationships in order to protect against the experience of depression. Rather, one or two high-quality relationships can, for many people, have a prophylactic effect by making the person less susceptible to episodes of depression.

People with depression tend to be dissatisfied with their friends and dating partners and seem to

engage in more conflict with them when compared to the relationships of people who do not have depression. Depressed people also report that their partners are more hostile and that they are frequently hurt or upset by them. It is important to note that these problems are most likely a complex combination of genuine problems in these relationships (e.g., conflict, unsupportive behaviors) along with depressed people's tendency to describe elements of their lives in negative terms. Cognitive theories of depression explain that the disorder is strongly associated with negative thoughts about the self, the world in general, and the future. Undoubtedly, this negative cognitive bias is responsible to at least some degree for reports of what appear to be the troubled personal relationships of people with depression.

Reasons for Relationship Problems in Depression

Depression and relationship problems clearly go hand in hand. Since the 1970s, social and behavioral scientists have worked to understand the many reasons for why depressed people have such trouble with their relationships. In one prominent theory, James Coyne argues that people with depression are unpleasant interaction partners. In fact, people with depression can induce a negative mood in other people, making them feel depressed as well. This phenomenon is known as *emotional contagion*. Because people do not enjoy spending time with others who bring them down, other people will often exhibit interpersonal rejection toward those with depression. Most people enjoy socializing but only with others who make them feel happy, excited, and interested. After interacting with a person who is depressed, many people prefer to avoid the depressed person in the future. This is likely one reason why people with depression often find themselves lacking intimate personal relationships. It is noteworthy that the interpersonal rejection of people with depression appears to be a fairly universal effect that cuts across many different types of personal relationships (e.g., friend, parent, spouse) and is even evident in interactions between strangers. There is something immediately apparent in the social behavior of depressed people that repels other people.

In an effort to explain exactly how and why people with depression tend to make others feel sad or depressed, scientists have focused on excessive reassurance seeking as an important interpersonal process in the maintenance of depression. This happens when the person with depression feels bad about himself or herself and frequently seeks reassurance from a relational partner. Partners will often provide this reassurance at first, although it may appear nongenuine to the person with depression. Eventually, this reassurance seeking becomes taxing and irritating to the relational partner, making him or her feel angry, sad, impatient, or upset with the depressed person.

Related to excessive reassurance seeking is the problem of interpersonal dependency among people with depression. This tendency reflects a very strong need for interpersonal attachments, coupled with doubts about their reliability and authenticity. Interpersonal dependency appears to be an important interpersonal risk factor for the development of depression.

Ironically, people with depression will sometimes intentionally seek and elicit negative reactions from other people. This process, known as *self-verification*, stems from the depressed person's desire to preserve their self-views and enhance predictability and control of their futures. By obtaining reactions from others who are consistent with their negative self-views, depressed people can acquire this sense of verification and predictability, albeit with other dysfunctional consequences that such interpersonal reactions entail. Experimental investigations show that seeking negative feedback from others is fairly robust among people with depression.

Another major line of research that can explain relationship problems associated with depression has focused on social skills deficits. People with good social skills can behave in ways that are appropriate to the relationship or social context and simultaneously are effective in achieving their interpersonal goals. Consequently, their social skills make it possible for people to obtain positive reinforcements from their social environment while avoiding punishing responses. Peter Lewinsohn was one of the early proponents of a behavioral model of depression that included the postulate that people with depression often have social skills deficits.

Depressed people generally describe their own social skills more negatively than their nondepressed

peers do. Again, part of this social skills deficit could be the result of a negative self-evaluation bias among people with depression. However, other research methods that involve partner (e.g., parent, roommate, friend, teacher) ratings or that observe the person with depression in an actual social interaction confirm the social skills deficit associated with depression. In addition, researchers have carefully studied numerous communication behaviors that are used in skilled conversation and find that depressed people often exhibit notable problems with these behaviors. These include, for example, less eye contact, slower speech rate, a more monotonous tone of voice, longer pauses, longer response latencies, less speech loudness, shorter speaking duration, having a sad facial expression, and fewer gestures. All of these behaviors add richness, excitement, and interest to human communication. However, depressed people will often fail to use these behaviors to their advantage, instead creating an impression of sadness, lack of interest, aloofness, or passivity. Social skills training is a therapeutic technique that has been developed to address such problems, often with good results.

The speech content of people with depression also reflects social skills problems. For instance, depression has been associated with increased discussion of negative well-being, dysphoric feelings, negative statements about the self, negative statements about peers, as well as criticism and disagreements. Such discussions do not ordinarily contribute to rewarding interactions. Accordingly, these and other social skills deficits might account for the interpersonal rejection and relational turbulence that is so commonly experienced by people with depression.

DETERIORATING RELATIONSHIPS

The optimism of newlyweds belies what is known about marital deterioration and divorce. Approximately 90 percent of Americans will marry at least once, and it is estimated that at any one time 20 percent of all marriages in the United States are significantly distressed. Given 56 million married-couple households in 2000, that is approximately 11.2 million marriages at risk of dissolution at any one time. Approximately 50 percent of first marriages in the United States end in divorce, and another 10 to 15 percent end in permanent separation. For those remarrying, the rate of dissolution is approximately 10 percent higher. Dissolution rates are harder to pinpoint for relationships without legal documentation (e.g., couples whose marriages deteriorate without divorce decree, same-sex partners who cannot legally marry, and partners who cohabitate). This entry provides an overview of relationship deterioration research, including known predictors, typical trajectories, and changes across transitions such as parenthood. The entry also provides a broad review of the literature on recovery from deterioration, including a review of clinical interventions and spontaneous recovery.

Typical Trajectories of Relationship Deterioration

Early studies attempting to assess the normative trajectory of marital satisfaction relied upon

cross-sectional data from spouses married for different lengths of time. Studies in the late '60s and early '70s suggested that marital satisfaction followed a U-shaped path, with newlyweds having the highest levels of satisfaction, followed by steady declines through middle age, and recovering to near-newlywed levels following the empty nest period. Cross-sectional data can be misleading, however, because the data being compared are snapshots in time gathered from separate cohorts rather than the trajectory of a single cohort (data collected from 65-year-old couples today do not necessarily predict what will happen for 35-year-old couples 3 decades from now). In contrast, more recent longitudinal studies have shown a steady and linear decline in satisfaction over time. Other studies have found substantial variability in individual trajectories, with many couples rapidly deteriorating over the first 4 to 7 years of marriage and others sustaining high levels of relationship satisfaction over time. Approximately 10 percent of couples report increasing satisfaction over the first 4 years of marriage.

The Dissolution Process

Steve Duck has described relationship deterioration as involving several dynamic processes. For example, *intrapsychic* processes involve one or both partners reflecting privately on dissatisfaction with the relationship. Although women typically tend to brood about declines in communication, men tend to focus on the absence of valued behaviors (e.g., the preparation of favorite meals) or responsibility for domestic duties. *Dyadic* processes involve the weakening of the relational culture through failure to uphold established patterns (e.g., no longer kissing each other goodbye or hello, forgoing after-dinner conversations, and other relationship-defining rituals). *Social support* processes involve the dissatisfied partner sharing complaints with others to enlist support and empathy. If partners decide to part, then *grave-dressing* processes occur during which the partners construct a narrative that makes sense of the deterioration. Finally, *resurrection* processes involve each person moving toward a future without the former partner.

Trajectories Across Transitions

Relationships are more likely to experience deterioration during times of transition. However, partners who successfully support each other through stressful transitions often report increased closeness. Stressful transitions include parenthood, the empty nest, and retirement, as well as acute and chronic circumstances such as disability, disease, and job loss. Researchers have found variability in couples' responses to stressful transitions. Most couples experience temporary declines in relationship satisfaction; for some, however, satisfaction improves.

Across the transition to parenthood, studies show variable trajectories. Some studies show 40 to 70 percent of couples report increased conflict and a decline in satisfaction. During the same transition, 33 percent of wives in another study reported stable or increased relationship satisfaction. Yet another study identified four typical trajectories for parents on scales of love, conflict, ambivalence, and maintenance: accelerating decline (5–16 percent of the sample experienced a period of relative stability followed by precipitous decline), linear decline (23–48 percent experienced steady decline), no change (22–47 percent), and modest positive increase (20–35 percent). Although trajectories vary, the central tendencies indicate linear deterioration. Couples that are more satisfied entering the transition to parenthood and that have better communication and relationship maintenance skills weather the transition better. Also, some evidence suggests that maintaining regular daily contact is characteristic of resilient couples.

Measuring Relationship Deterioration

Relationship deterioration is characterized by increasingly dysfunctional interaction patterns and increased susceptibility to a range of physical and mental health problems. Factors that have been found to contribute to relationship deterioration include severe dissatisfaction, emotional distance, frequent negative interaction, negative communication styles, perceived availability of alternative partners, and the absence of an extended social network. Other traits associated with greater susceptibility to relationship deterioration include

neuroticism, defensiveness, and parental divorce. Predictors can be categorized as involving cognitions, communication, conflict, context, and commitment.

Cognitions

Several studies have examined the effects of idealistic beliefs on relationship health. Within a sample of newlyweds, couples with positive marital behaviors (e.g., observed skill at communicating about marital problems) and positive attributions (e.g., viewing the partner in a more positive light) benefited from having high expectations about marriage. However, for those couples demonstrating more negative behaviors and attributions, higher relationship expectations predicted steeper declines in satisfaction—perhaps due to greater disillusionment in the absence of effective coping skills. It appears that holding high expectations contributes to relationship deterioration when those expectations are unrealistic.

Compared to happy couples, couples at risk for deterioration are more likely to endorse unrealistic beliefs about relationships. For example, distressed spouses are more likely to believe that disagreement in any form is destructive, that their partners are unlikely to change, and that rigid gender roles are desirable. Researchers have found a link between the number of unmet relationship standards and negative affect (e.g., anger), blame, and hostile communication styles. Another cognitive style linked to deterioration is a tendency to explain partner's negative behavior in conflict-promoting ways. For example, attributions such as “she rejected my sexual advance because she doesn't love me” or “he doesn't share his worries with me because he doesn't trust me” lead to increased conflict in subsequent encounters. This cognitive style is related to less effective problem solving with more displays of negative affect and steeper declines in marital satisfaction. In the case of intimate partner violence, aggressive individuals use verbal and physical aggression to express anger when their partners fail to meet their expectations.

Communication

Researchers have found a clear distinction between distressed and nondistressed couples in

the negativity of their communication. Distressed couples tend to engage in escalating negative communication patterns that often lead to significant emotional withdrawal and preclude effective problem solving. For example, the demand-withdraw pattern is common among distressed couples (interactions in which one partner's demands for change are met with increasing withdrawal by the partner). Withdrawal tends to elicit escalating demands for change, resulting in even more withdrawal. Andrew Christensen has studied this phenomenon extensively and found it to be a significant predictor of relationship deterioration. A similar pattern, harsh start-up, occurs when partners begin a discussion with criticism or sarcasm. Research by Gottman has demonstrated that the quality of a couple's start-up predicts the quality of the entire interaction, which in turn has been repeatedly associated with marital deterioration. Another significant predictor of deterioration is negative affect reciprocity, a pattern in which partners engage in long, escalating tit for tat sequences of negative behavior (e.g., criticize-defend). Distressed couples appear to have great difficulty exiting these negative sequences. Researchers have identified negative affect reciprocity as one of the most consistent correlates of marital dissatisfaction.

Within a closed system (all predictors and outcomes already being known), statistical models can be constructed from which dissolution and divorce can be predicted with a great deal of accuracy (ranging from 80–94 percent) based on oral history interviews and observational coding of problem-solving interactions. Gottman has identified four communication patterns that predict marital deterioration: criticism, contempt, defensiveness, and stonewalling. These predictors form a cascade of increasing deterioration—the more present, the greater risk of divorce.

1. *Criticism*. Unlike a complaint that addresses a specific behavior, criticism targets a spouse's personality or character. Doing so limits the partner's ability to respond and instead invites defensiveness and escalating negativity. Criticism pollutes the communication stream by making it virtually impossible to hear the underlying complaint.

2. *Contempt*. Contempt is feedback given with the intent to insult and/or psychologically abuse the partner (e.g., sarcasm, cynicism, name-calling,

eye rolling, sneering, mockery, and hostile humor). Its toxicity lies in the conveyance of disgust, heightening conflict rather than resolving it. Contempt, especially for wives, is the best single predictor of divorce. Husbands' contemptuous facial expressions have been found to predict the number of infectious illnesses wives will suffer even 4 years following an interaction.

3. *Defensiveness*. Defensiveness occurs when one partner defends against complaints and criticisms. Defensiveness escalates conflict because it fails to address the underlying complaint.

4. *Stonewalling*. Stonewalling emerges when conflict escalates to the point where at least one partner has physically or emotionally disengaged. The silent treatment, monosyllabic answers, and physically removing oneself from the room are types of stonewalling that lead to further relationship deterioration. Although gender differences are not universal, stonewalling tactics are more common in men.

Conflict

Couples inevitably encounter conflict—the ways that couples manage that conflict predict relationship satisfaction. Although some conflict is necessary to address problems and facilitate change, conflict can easily overwhelm a relationship, leading to deterioration. Although dissatisfying in the short run, nonhostile conflict has been associated with long-term gains in relationship health. At the same time, conflict occurring at a rate greater than approximately 20 percent of interactions predicts relationship decline.

Gottman has identified three types of conflict styles (volatile, validator, and avoider) common in stable marriages (those likely to remain married) and two types (hostile and hostile-detached) common in unstable marriage (those likely to divorce). Volatile couples demonstrate high levels of both negative and positive affect, and their interactions are characterized by a great deal of mutual persuasion. Validator couples tend to discuss issues more thoroughly and work toward compromise. Avoider couples tend to avoid conflict, most often resolving issues by agreeing to disagree. In all three, there is a reasonable balance between conflictual and positive interactions (roughly a ratio

of five positive to every one negative interaction). Hostile couples engage in hostile and defensive conflict. In hostile-detached couples, spouses remain detached and emotionally uninvolved with each other, engaging only in brief bouts of attack and defensiveness.

Comparison of same-sex and heterosexual couples indicated that frequent conflict contributed to deterioration in both types. Conflict over intimacy and power were the sources of conflict most likely to result in lower levels of relationship satisfaction.

A partner's ability to accept his or her partner's influence also predicts relationship quality. During problem-solving interactions, some husbands escalate the level of conflict (considered rejecting influence), and others maintain the conflict at a steady level (accepting influence). Husbands who did not escalate the conflict (while also not withdrawing from it) showed better relationship outcomes. In contrast, subsequent research has shown that in domestically violent relationships men do not accept influence from their wives.

Researchers have found that as many as 74 percent of couples seeking marital therapy have been physically aggressive within the last year, yet fewer than 5 percent report physical aggression as a specific problem. Even mild, infrequent aggression has been associated with negative individual and relationship outcomes. Intimate partner violence (perpetrated by both men and women) is associated with several factors that contribute to relationship deterioration, including physical injury, fear, depression, and post-traumatic stress disorder. Intermittent and unpredictable abuse precipitates relationship deterioration by eroding trust, intimacy, and emotional support. Intimate partner violence is a strong predictor of relationship decline even after controlling for stressful events and negative communication.

Context

Researchers have also begun to explore the effect of context on relationship deterioration. For example, research on diary entries reveals that on days that couples have high levels of general stress and competing demands, they are more likely to have more stressful marital interactions. Similarly, data on work spillover suggest that arguments at work are related to arguments at home.

Data indicate that economic stress is also associated with marital deterioration and increased marital conflict. Studies also find the use of alcohol and other drugs is significantly related to intimate partner violence and marital deterioration. In addition, the stress of incarceration can be overwhelming. Intimacy is disrupted due to limited contact and the problems associated with accusations and assumptions of infidelity. Economic uncertainty increases with the loss of income during incarceration and subsequent problems gaining employment once released. Some researchers have suggested that studying the struggle between couples and their environments is at least as important as studying the interpersonal struggles that couples face in order to understand the full range of factors involved in relationship deterioration.

Commitment

Commitment affects several aspects of couple functioning that predict dissolution. Theory identifies two main components of commitment, personal dedication (the degree to which partners are intrinsically committed to each other) and constraint (the conditions that make it more difficult for a partner to leave—such as finances, children, and a lack of alternative partners). Couples at risk for deterioration are those who demonstrate a commitment pattern that is low on personal dedication but not necessarily low on constraints. This pattern is apparent even in newlyweds, with low initial commitment levels serving as substantial predictors of eventual relationship dissolution.

Treatment

The treatments for marital deterioration that have most consistently demonstrated efficacy include Traditional Behavioral Couple Therapy, Cognitive Behavioral Couple Therapy, Emotionally Focused Couple Therapy, and Integrative Behavioral Couple Therapy. Studies have shown that couple therapy can be an effective treatment for relationship discord, consistently outperforming no-treatment control conditions. In short, these treatments result in better outcomes than seeking no treatment at all. However, couple therapy does not produce clinically significant change for all couples.

Slightly fewer than half of treated couples experience a reverse in deterioration that moves both partners from the distressed range into the nondistressed range. For those couples who improve over the course of therapy, as many as one third continue deteriorating posttherapy and have relapsed by 2-year follow-up. Treatment effects tend to be well maintained at 1-year follow-up, suggesting that prevention programs based on yearly checkups may prove useful in maintaining therapeutic gains over time by keeping deterioration at bay.

Donald Baucom and his colleagues have reviewed empirically supported couple and family interventions. Across more than 20 outcome studies, they found no evidence of an appreciable level of spontaneous recovery among couples placed on a waiting list for marital therapy. However, one research team discovered what does appear to be spontaneous recovery by using data collected from over 5,000 adults interviewed in the late 1980s. When asked to rate their marriages 5 years later, two thirds of those unhappy marriages that avoided divorce had become happy. Focus groups held with 55 of the formerly unhappy spouses found that many had experienced extended periods of marital unhappiness, including alcoholism, infidelity, and depression. Although approximately one third of those couples had sought marital counseling, approximately two thirds experienced some level of spontaneous recovery. These findings warrant further research to determine whether the pattern of marital deterioration in community samples is distinct from those of clinical samples or whether spontaneous recovery may exist only as a function of imprecise methodology.

Need for Prevention Strategies

As relationships deteriorate, the damage can become increasingly irreversible. Over time, negative patterns of interaction typically become entrenched and thus resistant to change. Couples who experience severe and prolonged distress demonstrate low motivation to pursue change in the relationship, hence have poor to modest rates of long-term success with intensive couple therapy. Similarly, when affection is low, such as minimal tenderness or infrequent sexual intimacy, couples typically respond more poorly to therapy.

After detecting serious marital difficulties, couples often delay seeking help for an average of 6 years during which time the relationship progressively deteriorates. Long-established distress predicts poor response to couple therapy. Hypothesizing that better results may be achieved through earlier interventions, some researchers have established brief relationship modules for at-risk couples. Various relationship education programs have been shown to help moderately distressed couples improve their communication and relationship satisfaction—even at a 2-year follow-up.

James Córdova has developed a prevention program modeled after the regular physical health checkup, called the Marriage Checkup. The Marriage Checkup is comprised of a pair of sessions beginning with a thorough assessment session (utilizing empirically derived predictors of relationship deterioration) followed 2 weeks later with a motivational feedback session. During the feedback session, the therapist provides a succinct history of the couple's oral history, explains scores on marriage questionnaires, summarizes the partners' abilities to problem solve and affectively communicate, and uses motivational interviewing to make recommendations tailored to the couple's specific areas of concern. Results from both an open trial and a small randomized control trial have demonstrated increased relationship health in both husbands and wives immediately and at a 2-year follow-up. A larger study is currently underway.

Marriage and relationship education (MRE) includes programs offered by private professionals, clinical researchers, and lay practitioners. One meta-analysis of MRE programs found that the programs' effects on marital satisfaction-quality were modest but significant. One such program, Prevention and Relationship Enhancement Program (PREP), has shown evidence of decreasing negative interaction, lowering rates of breakup and divorce, and increasing levels of relationship skills maintained up to 5 years following the training. In one sample, couples who completed PREP had a divorce rate of 3 percent compared to 16 percent for control couples, a promising finding. Relationship scientists are still discovering prevention and intervention strategies to help individuals select appropriate mates, to keep the relationship healthy from the beginning, to repair relationships when

problems arise, and to dissolve amicably when deterioration occurs despite best attempts.

DEVELOPING RELATIONSHIPS

When asked to list the most important things in their lives, most people list their relationships. Good health, money, and career success eventually make the list, but friends, family, and romantic partners are typically at the top. This is no surprise. Close relationships are a source of social and emotional support, self-validation, identity expansion, encouragement, and affection. Therefore, understanding the process by which relationships develop is important and has been of interest to relationship scholars for several decades. Of course, scholars who study the process

of relationship development face a formidable task. They seek to explain how a jointly constructed, mutually enacted, and highly coordinated behavioral and emotional connection between two people emerges from the ordinary circumstances of social interaction. This entry summarizes several approaches to explaining relationship development found in the scholarly literature, particularly the phase or stage models and turning-points analysis.

Phase or Stage Models of Relationship Development

Phase or stage models of relationship development recognize that romantic couples and friendships move through and between phases at different rates of speed. Some romantic couples, for example, describe their relationship as beginning with love at first sight and accelerating quickly to a committed relationship or marriage. Others describe their relationship development as more gradual, developing a friendship first, entering a prolonged courtship, and moving slowly to marriage. And some couples that had romantic potential do not progress beyond relatively superficial interactions; they remain at the level of casual acquaintances if professional or social networks keep them in contact or they terminate the relationship entirely if no external factors necessitate continued interaction. Thus, the goal of scholars who offer models of relationship development is not to specify how soon into the relationship any particular transition is likely to occur. Rather, their goal is to identify patterns of emotions, attitudes, and behaviors that distinguish one phase of development from the previous and the subsequent phase. The three models summarized below are widely accepted illustrations of the phases or stages of development.

One of the first models concerned with the phases of development in friendships and romantic relationships was published by George Levinger in the early 1970s. His model of pair relatedness describes levels of increasing connection, interdependence, affection, and commitment as the dimensions of relationship development. The four levels of relatedness include: (1) zero contact and zero relatedness, (2) unilateral awareness where the

individuals are aware of each other but have not had an interaction, (3) surface contact during which there is some interaction but individuals are still independent rather than interdependent, and (4) mutuality beginning with minor intersection, moving to major intersection, and ending with total unity. During the period of mutuality, partners develop a widening range of shared rules and norms, deeper knowledge of each other, greater responsibility for each other's outcomes, and experience deepening affection and commitment. Levinger illustrates the increasing connection during mutuality as two circles moving from slight to complete overlap.

Interestingly, Levinger notes that in arranged marriages, much of what occurs during the early phases in mutuality is accomplished by the parents who assess similarity, resources, compatibility, and so on. In arranged marriages, therefore, commitment is established at the time of the marriage; knowledge of partner, affection, and love emerge later.

The important theme in Levinger's description of relationship development is his analysis of what the increasingly diverse connections mean to partners. He explains that the connections eventually become causal links in which one person's actions or emotions literally cause a change in the other person's actions or emotions. For example, a bad day at work may cause John to act more distracted or contentious than usual when he talks with Mary; his behavior may cause Mary to feel an emotional response, perhaps sympathy or irritation (depending on previous interactions). Mary is then motivated to ask what's wrong, and a conversation emerges from and is shaped by the causal links between John and Mary. When causal links help partners attain their goals, satisfaction tends to be high. When they constrain goal attainment, satisfaction tends to be low. In the latter case, partners may respond by limiting the number and extent of the causal links.

A second stage model of relationship development was offered by Irwin Altman and Dalmas Taylor, also in the early 1970s. This model was also concerned with interdependence but placed its emphasis on communication, particularly breadth and depth of self-disclosure. The model was aptly termed Social Penetration Theory to highlight the process of moving beyond the public self to a

deeper understanding of the private self. Altman and Taylor used the now classic metaphor of the onion to represent layers of increasingly personal information about the self: surface, peripheral, intermediate, and central. Like peeling layers off the onion to reach its inner core, people in developing relationships typically reveal superficial information about their background, interests, habits, and so forth before they reveal intimate information that makes them vulnerable to criticism, rejection, or exploitation.

The Social Penetration Model describes four stages distinguished by the breadth and depth of disclosure: (1) Orientation refers to initial interaction when a relatively narrow range of topics is discussed and depth is at the surface level; (2) exploratory affective exchange includes a wider range of topics with some depth, although mostly at the peripheral level; (3) affective exchange includes increasingly personal and risky disclosure involving a wide range of topics at the intermediate levels and a few at the central layer (although some information is still guarded); and (4) stable exchange is characterized by open communication at all levels—surface, peripheral, intermediate, and central.

Movement through these stages is influenced by four overlapping processes. First, the uncertainty that characterizes initial interactions is an uncomfortable mental state because it is difficult to predict what the other person might say or do. In role relationships guided by interaction scripts, predicting the other person's actions is easy to do (e.g., a grocery clerk rings up the items, announces the total cost, processes the payment, and says, "Have a good day"). In developing relationships, self-disclosure allows people to reduce their uncertainty by learning more about each other—at first, basic demographic information (e.g., hometown and occupation) and then increasingly personal information (e.g., values and attitudes). Second, the norm of reciprocity encourages people to reciprocate both the valence of self-disclosure (positive or negative) and the level of intimacy. By matching valence and level of intimacy in self-disclosure, people feel that their interactions are equitable or balanced, and this contributes to relational satisfaction. Third, self-disclosure tends to increase liking, and liking tends to increase self-disclosure, a cycle that facilitates attraction and continued relationship growth, unless initial disclosures reveal

significant incompatibility. Fourth, the manner in which a recipient responds to the other's self-disclosure (called responsiveness) underlies the first three processes described above. Research indicates that when a person responds with perspective taking and valuing (i.e., trying to understand the disclosure and validate the discloser's feelings without being judgmental or changing the topic), the discloser feels accepted, rates the conversation as warm and comfortable, likes the recipient better, and expresses a greater desire to develop the relationship.

Of course, Altman and Taylor are careful to remind readers that people are more complicated than onions. Developing relationships do not simply move in a linear path of increasing breadth and depth of disclosure. In actual practice, relationships cycle through periods of relatively superficial interactions and periods of more intimate interactions. In addition, the social penetration process may reveal differences as well as similarities, topics that cause conflict, and past behaviors that make partners less secure about the future of the relationship. Potential friends or romantic partners may be able to work through the differences, may learn to avoid problematic topics, or may decide to reduce the level of involvement by not reciprocating the other person's breadth and depth of self-disclosure.

Finally, Altman and Taylor acknowledge the challenge for couples to manage the tensions they feel as they reveal more about themselves and become increasingly interdependent. These tensions are called dialectics because they are seemingly opposite needs that can be desired at the same time. For example, a person might want to be fully open with a close other while wanting to protect his or her privacy or to be fully connected to a close other while wanting to retain autonomy. Successfully managing dialectical tensions such as openness-closedness, autonomy-connection, and novelty-predictability is an important aspect of relationship development. Too much openness and connection can eventually lead partners to feel like they have lost their individual identities; too much predictability can lead to boredom, and too much novelty can lead to chaos and relational insecurity.

Recent investigations have identified the strategies that members of close relationships use to manage dialectical tensions and their association with relationship quality. Selection involves choosing one side of the dialectic over the other (e.g.,

deciding to be fully open about everything and have no secrets or being very private with personal information). Separation involves moving from one side of the dialectic to the other depending on circumstances or topic (e.g., being completely open about relationship issues but closed about politics and religion). Neutralization involves choosing a middle ground between the extremes (e.g., being somewhat interdependent in social activities but also retaining some autonomy or being moderately open and expressive). Finally, reframing is a sophisticated strategy that involves viewing the poles as complementary rather than as contradictory (e.g., interpreting a partner's occasional desire for time apart as a way to make time together more special). Reframing is generally found to be the most effective management strategy for maintaining relationship satisfaction, and selection is found to be the least effective strategy.

Mark Knapp proposed a third model of relationship development in the early 1980s called the Staircase Model. This model presents five stages or steps, with higher steps representing increased levels of intimacy and commitment. The coming-together stages include (1) initiating, which involves superficial communication and exchange of basic information (greetings, polite conversation, introductory information) in an attempt to make a positive first impression and reduce initial uncertainty; (2) experimenting, in which individuals begin to discover each other's likes and dislikes in order to determine if they want to pursue a relationship (small talk with moderate self-disclosure); (3) intensifying, in which both breadth and depth of communication increase and commitment and affection are expressed (nicknames, using *we* rather than *you* and *I*; saying "I like" or "I love you"); (4) integrating, which involves a merging of individual identities into a relational unit as romantic partners or best friends and being recognized as such by the social network; and (5) bonding, in which individuals publicly commit to each other, usually through some type of cultural ritual (such as marriage). Knapp notes that not all relationships progress through the steps in the model. Some stabilize at a low step or move back down the stairs and terminate.

An important contribution of the Staircase Model is its emphasis on how dimensions of communication change as relationships develop or

alternatively, reverse as relationships decay. Specifically, the amount and depth of self-disclosure are not the only changes in communication. According to Knapp, other changes include movement along the dimensions of communication that he labeled *stylized to unique* (i.e., formal-conventional to relationship-specific), *difficult to efficient*, *rigid to flexible*, *awkward to smooth*, and *hesitant to spontaneous*. In addition, communication moves from overt judgment suspended to overt judgment given. For example, few people on a first date would criticize the other person's hair style or driving but would be comfortable doing so at later stages of development. Studies of romantic couples and college student friends indicate that their conversations are indeed characterized by efficient, unique, personal, and spontaneous communication compared to conversations of strangers. Inside jokes, nicknames, teasing insults, and unfinished but fully understood comments are all manifestations of the idiosyncratic and personalized communication that develops in close relationships.

In sum, although these phase or stage models use different terms, they share the view that relationship development involves change on several dimensions. First, emotional investment develops as the range and intensity of both positive and negative emotions experienced and expressed increase. Second, independence yields to interdependence as each partner's thoughts, decisions, emotions, and actions increasingly influence the other person's thoughts, decisions, emotions, and actions. Third, each partner's public self is adapted to a relational self as generalized social competence during interaction becomes a relationally specific competence that reflects the particular needs and expectations of both people in the relationship. Fourth, social norms evolve into relational norms as couples develop their own standard for appropriate and expected behavior, which defines them as a romantic couple or best friends. Finally, public communication moves to interpersonal communication and eventually to relational communication as couples reveal more personal information and construct unique communication practices.

Turning-Points Approach to Relationship Development

The turning-points perspective shifts the focus from models characterizing progression through phases

or stages of development to relationally significant events that prompt one or both members of a relationship to (re)evaluate the strength of their commitment to the relationship and each other. Some events make one or both partners realize how much they care about each other, and commitment increases. Other events make one or both partners question whether the relationship is worth continuing, and commitment decreases, at least temporarily. Couples who stay together work through the negative event, and eventually their commitment returns to its previous level or rises to a level higher than it was prior to the turning point.

Leslie Baxter and her colleagues have identified a number of turning points by asking couples to look back over their time together and to describe an event that caused a change in their relationship. In some studies, romantic couples are also asked to mark on a graph how much commitment they felt at the time of that event, a method that measures increases or decreases in commitment. The turning points most often reported include get-to-know time (e.g., first meeting, first date), quality time (e.g., time away from others, a deeply meaningful conversation), physical separation (e.g., business trip or separate vacations), reunion, external competition (e.g., a romantic rival or external demands from work, school, family), passion (e.g., first kiss, first sex, "I love you"), conflict (e.g., first big fight), making up, disengagement (e.g., considering or actually breaking up for a time), relationship talk (e.g., explicit conversations about relationship norms, quality, definition, or direction), positive psychic change (e.g., realizing strong positive emotions toward partner or relationship), negative psychic change (e.g., realizing strong negative emotions toward partner or relationship), exclusivity (e.g., agreement to not date others), serious commitment (e.g., living together, marital plans), sacrifices (e.g., crisis help, special favors), and network interaction (e.g., including partner in functions with family, friends, and coworkers).

Research offers several insights into how turning points are related to other relationship dimensions and processes. For example, when romantic couples identified the passion turning point as a significant transition in their relationship, they also reported a greater need to balance three dialectics: openness-closedness, autonomy-connection, and novelty-predictability. In other research on the

passion turning point, individuals who reported saying "I love you" prior to their first sexual involvement reported greater commitment, satisfaction, and relationship stability compared with those who did not.

Turning-points analysis has not been limited to romantic relationships. Friends also report transitional events within their relationships, such as the first big fight and quality time. Platonic friends sometimes realize that they would like to redefine the relationship as romantic based on the positive psychic-change turning point. Finally, blended families that are navigating the sometimes difficult process of integrating previously separate family units into one new family often report that turning points such as get-to-know time, quality time, and network interaction facilitate the integration process. Turning-points analysis of blended families indicates that when changes in feeling like a family are graphed in the same way that commitment is graphed for romantic relationships, five trajectories emerged: accelerated (rapid development based on numerous positive turning points), prolonged (slow but steady development with more positive than negative turning points), turbulent (a roller coaster pattern of positive and negative turning points), stagnating (consistent low feelings like a family with few turning points), and declining (more negative than positive turning points).

Conclusion

Although phase models and turning-points analysis are presented separately in this entry, these approaches to relationship development overlap. Turning points occur within stages and sometimes function to alert partners that they have progressed to a more advanced stage. Research in both approaches has contributed substantially to the field's understanding of relationship development in friendships, romantic relationships, and blended families. Together they provide a framework for integrating research on factors that affect the development process. For example, personality characteristics, such as shyness, introversion or extraversion, self-monitoring, love styles, attachment styles, and fear of intimacy, may shape the direction or pace of relationship development. Likewise, cultural norms for appropriate sex-role

behavior may lend characteristic differences in the same-sex friendships of men and women. For example, more intimate self-disclosure is evident in women's friendships compared to men's except in friendships that men consider to be their closest friend. Finally, these approaches are useful guides for recent investigations of online relationship development in which face-to-face interactions may occur after, rather than before, substantial self-disclosure.

DEVELOPMENTAL DESIGNS

Developmental research designs are intended to capture information about how individuals change over time and the processes through which those changes occur. Like many researchers with interests in close relationships, developmental researchers hope to predict the quality and stability of close relationships and both adaptive and maladaptive functioning within them. Developmental approaches to stability and change, however, involve examining relationship phenomena in connection with individual functioning in different life periods. This entry describes designs commonly used to address questions pertaining to close relationships in particular life periods, the transformations that may occur in particular dyads across time, and the functional significance of these relationships for individuals and later relationships.

Developmental research on relationships encompasses diverse questions. Some researchers are interested in the timing or onset of relationship events. For example, a researcher might be interested in determining the age at which adolescents first experience a significant romantic relationship and/or the determinants of this transition (e.g., puberty, community norms, peer pressure, gender). Researchers also often wish to identify the important factors in whether individuals can maintain those relationships. Others might be interested in examining and accounting for age-related differences in relationship functioning (e.g., the nature of friendship in early adulthood as compared to adolescence). Developmental, longitudinal studies likewise can inform many research questions regarding adult relationships. The nature, course, and processes of adaptation to major relationship changes, such as divorce or the death of a partner, are both common and significant experiences of individual development to which developmental designs are uniquely well suited.

An underlying goal when using these designs is capturing the emergence of and successive transformations in competencies relevant to age-appropriate social functioning. Accordingly, one could ask whether the processes related to effective romantic relationship functioning are different in adolescence and in adulthood or whether similar processes are implicated in maladaptive

relationships, as compared to adaptive ones. In true developmental designs, the same participants are assessed at multiple time points (longitudinal designs). Some questions relevant to the study of development may be informed by other research approaches as well. The next sections of this entry describe the most common designs used in developmental research on close relationships.

Cross-Sectional Designs

Cross-sectional designs involve a single time of measurement and are commonly used by researchers to compare groups. Although not inherently developmental, cross-sectional studies can be useful for assessing when important developmental milestones in close relationship phenomena are commonly achieved in a particular sample. For example, one could determine how commonly adolescents of differing ages (e.g., ages 13, 16, and 19 years) engage in sexual activity and whether the frequency of differing sexual behaviors differs for adolescents of varying ages. Age-group comparisons are insufficient for determining whether experiences in one developmental period carry forward to subsequent periods. Moreover, comparisons of multiple age groups at a single time point confound development with cohort (the effect of having been born at different times and thus, having experienced particular cultural and historical conditions; individuals born before and after the invention of birth control pills constitute different cohorts, as well as different age groups). Consequently, cross-sectional designs are not appropriate for examining individual development. Nevertheless, cross-sectional studies are efficient tools for collecting information from participants of varying ages, and the resulting information can be used in determining the optimal period of time over which to track the development of individuals and their relationships. Understanding the impact of developmental history on functioning at different times in development, however, requires longitudinal designs.

Longitudinal Designs

Longitudinal researchers track the continuity of and changes in particular phenomena by studying

the same participants repeatedly over time. For example, researchers have charted changes in relationship satisfaction from the start of the marriage across subsequent intervals. By using the same measure across times of measurement, these researchers examined homotypic continuity, that is, the similarity among measures of relationship satisfaction at multiple times. The researchers can compare across differing times with relative ease and can directly observe the stability of a given construct.

In a developmental longitudinal study, the researchers also examine how events in an individual's developmental history predict continuity and change in marital satisfaction over time. Times of measurement are typically chosen on the basis of theoretically derived expectations or previously reported empirical findings that show particular ages to be especially likely points of change in one or more of the focal constructs guiding the research. Developmental longitudinal studies contrast with nondevelopmental designs in several ways. One is that developmental longitudinal designs permit researchers to study development prospectively, thereby providing a more accurate account of the nature and course of relationship functioning from one time in life to the next than is possible with retrospective reports of developmental history. Retrospective accounts are subject to bias and distortion. If an individual reports having poor relationships with romantic partners and also reports having poor relationships with prior romantic partners, researchers cannot determine whether the account is accurate or whether perceptions of prior relationships are contaminated by experiences in the current relationship. With developmental longitudinal studies, however, one can compare prospective and retrospective accounts of behavior to determine the accuracy and functional significance of retrospective memory.

Another contrast is that developmental longitudinal studies examine how individuals navigate age-appropriate developmental tasks and whether their competencies at one time point predict functionally relevant competencies at later time points. Studying marital satisfaction from a developmental perspective, for example, might entail questions such as whether functioning in prior important relationships (e.g., with parents in early childhood, peers in middle childhood, friends in adolescence) predicts adult marital satisfaction and functioning.

Third, it is often the case in developmental longitudinal studies that the defining characteristics and issues of a particular construct may vary across developmental periods. Thus, to assess continuity and change, researchers must rely on different but functionally equivalent measures at differing time points. Functionally similar behaviors assessed in differing ways across development are said to manifest heterotypic continuity. An example of research requiring heterotypic measures of relationship phenomena is assessments of attachment security. Security is assessed in terms of the extent to which individuals effectively use their relationships with attachment figures to regulate emotions and resolve feelings of distress. How security is manifested and the conditions that elicit behaviors indicative of security should change depending on the age of the individual or on the type of relationship partner (e.g., parent-child, close friend, or romantic partner). To assess the attachment security of a preverbal 12-to-18-month-old infant, researchers commonly use the Strange Situation procedure to look for patterns of behavior in response to stress. In this procedure, invented by Mary Ainsworth, infants experience multiple unexpected changes in which the caregiver, an unfamiliar adult, both, or neither are present with the child. Secure relationships at this age are typified by the child's maintaining proximity to the caregiver, who is the most likely source of reassurance and support and who is an instrumental resource. Assessment criteria include whether children are able to make effective use of the caregiver to reduce the child's distress in the face of pressure to complete a challenging task, to remain calm in the presence of unfamiliar persons, and to function as a secure base for the child even when not in direct physical contact. Observers also classify caregiver-child pairs on the degree to which child and caregiver effectively play their respective roles in these interactions. Observers note whether children, when distressed, seek proximity to their caregivers, are quickly calmed by their caregivers, and can return to exploratory behavior.

If one's goal is to assess an adult's attachment security to a significant other person, however, the Strange Situation is not a useful method. Adults should no longer become highly distressed when proximity with the attachment figure is lost. Further, when adults are distressed, the behavioral

manifestations of security should be different. Consequently, researchers seek assessment methods that are sensitive to adults' perceptions that partners willingly provide sensitive support, acceptance, and so forth. Predictably, measures of adult attachment security are typically verbal—interviews or inventories that assess the adults' cognitive representations of their memories and feelings regarding attachment-relevant experiences.

Several notable developmental longitudinal studies have tracked individuals and their relationships from infancy to adulthood. Some are large ongoing cohort studies tracking participants from early childhood to adulthood, such as the Dunedin Longitudinal Study in New Zealand and the National Institute of Child Health and Human Development Study of Early Child Care and Youth Development in the United States. One notable cohort study of relationships, the Minnesota Longitudinal Study of Risk and Adaptation, began as a prospective study of high-risk children and their parents and significant relationships. The study exemplifies developmental longitudinal research in its use of multiple methods of assessment and multiple informants and its attention to the nature and trajectories of functioning across multiple measurement points from birth to age 28. Particular attention has been given to the importance of relationships in development and to continuity and discontinuity of behavior in dyadic relationships across the life span.

Despite distinctive advantages, developmental longitudinal studies present several methodological and logistical challenges. First, they are costly and time consuming, requiring considerable diligence and effort to track and retain participants. The studies mentioned above have achieved remarkable participant retention by frequently contacting individuals between measurement points. The Minnesota Longitudinal Study, for example, has retained 65 percent of its original participants after 28 years; moreover, the current sample ($N = 174$) and the attrition ($n = 93$) group do not differ significantly with respect to the initial recruitment criteria. Second, the incidence of relationships or relationships of particular types may vary from one measurement point to the next, increasing the likelihood that data on an individual's

relationships may be present at some times and not at others. Strategies for handling missing data have been discussed extensively by methodologists concerned with longitudinal designs. Third, developmental longitudinal studies generate correlational findings, leaving open questions of causality or direction of effects. However, predictions across time provide stronger evidence for possible causality than cross-sectional studies do.

Sequential Designs

To address the drawbacks inherent with both cross-sectional and developmental longitudinal designs, hybrid designs have been devised. These designs permit the simultaneous study of age groups and the individuals within them. Researchers using sequential designs follow subjects from multiple age groups and assess them repeatedly over time. For example, in a sequential study of romantic relationships, one might track one set of couples who were recruited at age 18, while simultaneously tracking a group of couples recruited at age 20. These couples might complete assessments every 2 years over a 6-year period. Data from sequential designs permit three possible comparisons: the 18-year-old couples with 20-year-old couples at the first assessment, 20-year-old couples with 22-year-old couples at the second assessment, and 22-year-old couples with 24-year-old couples at the third assessment. Further comparisons are possible by following each couple across multiple assessments. Finally, sequential designs also permit cohort comparisons by examining whether the 20-year-old couples assessed in the first assessment differ from the 20-year-old couples assessed in the second assessment and by examining whether the 22-year-old couples assessed in the second assessment differ from the 22-year-old couples assessed in the last assessment. Using sequential designs enables researchers to rule out the possibility that results can be attributed to cohort effects.

Developmental designs thus potentially make it possible to examine the phenomena of relationships in the context of prior significant relationships and the prospect of future ones. Although such studies commonly attempt to predict the nature and significance of adolescent or adult

relationships based on information about childhood relationships, other more differentiated questions also hold promise for better understanding of variations in relationships. An example is research to identify the processes that link experiences in very early caregiving relationships to subjective emotional experiences in adult romantic ones. Drawing from a developmental longitudinal data set, Jeffry Simpson and colleagues demonstrated that the relation between the two was mediated by the impact of early relationships on peer relationships in childhood and close friendships in adolescence. Revealing how relationships of different types are meaningfully linked across time requires the distinctive features of truly developmental designs.

DEVIANCE, RELATIONSHIP EFFECTS

Part of human existence is to feel a sense of belonging and closeness with others. As such, interpersonal relationships play a central role in living one's life. Yet laypersons and social scientists alike recognize that some relationships, individuals, and behavior are considered deviant, according to societal norms. This entry describes social scientific perspectives on how deviance is defined in relationships; namely, how some relationships are viewed as deviant in our society, how particular behaviors within relationships are regarded as deviant, and how deviance can be defined by the actions or abilities of individuals.

Deviant Relationships

Perhaps surprisingly, there is little consensus among the public and scientific communities about how to define deviance, thereby affecting how certain relationships may be considered deviant, what constitutes deviant behavior, and who would be considered a deviant individual. One way researchers define deviance is by marking any behavior that violates an established social rule or convention as deviant. Thus, certain types of relationships might be considered deviant because they are based upon behavior that violates social norms. For example, because mainstream society believes that intimate relationships should be between two adults, romantic relationships between adults and minors, such as between teachers and students or those advocated by the North American Man/Boy Love Association, would be considered a violation of social norms and thereby deviant.

Another fundamental assumption of romantic relationships is that the relationship is consensual, meaning that both parties consent to being involved. Therefore, any relationships involving minors, bondage, long-term abduction, and/or psychological entrapment would be considered deviant. For instance, relationships built by individuals who kidnap and imprison another person, often for the former's sexual gratification, would be considered deviant because they involve a nonconsenting party. Additionally, relationships characterized by

instances of date or marital rape or long-term psychological maltreatment would also qualify as deviant because they violate the consensual norm. Relationships between prisoners and guards or abductees and captors (such as prisoners of war) might also be considered deviant because of the limited degree of autonomy and the power distance influencing the degree of consensuality between the parties. Violations of such standardized relational assumptions can have serious long-term implications for the individuals involved—especially those persons who are in the less powerful position. Being in such a position could leave the less powerful feeling victimized and traumatized, leading to psychological scarring that could affect the person's ability to function and form healthy bonds in the future.

Most would agree that many of the above-noted examples are clear violations of social norms. However, there are also examples that, in the purest sense of the word, violate social norms but would not be considered deviant by all. For instance, homosexual relationships might be considered deviant by some individuals because they violate the privileged heterosexual norm of American society. Moreover, some might view arranged marriages as deviant in U.S. culture because they do not involve two fully consenting adults. These examples highlight the importance of the fact that because norms are socially constructed, fluid, and dynamic, so too is society's definition of what constitutes normal and thereby, nonnormal or deviant. As such, what is considered socially deviant is not fixed but rather constantly changing. Understanding the fluidity and dynamism inherent in the social construction of deviance is important because it highlights how standards for what is considered normal are developed by those in dominant power positions and how others, because of their subordinate social positions, are marginalized and deemed deviant because they do not live up to the standards and norms established by the powerful.

Deviant Behavior in Relationships

Another way to characterize relationships as deviant is by the presence of deviant behavior

within an outwardly looking normal relationship. For example, swinging (nonmonogamous sexual activity of relational partners) or relational violence would be deemed deviant because it violates underlying normative assumptions of coupling: monogamy and healthy regard for partner. Drug and alcohol abuse, particular sexual acts (such as sadomasochism), participation in nudist organizations, and pornography consumption are other examples of relational acts that might be considered deviant by today's society. Particular behavior enacted in organizations could also fall under this deviance rubric because the actions violate social norms of proper and ethical workplace etiquette. Acts such as superior-subordinate romantic involvement and the wall of silence among police officers maintained to protect illegal or unethical acts of their brethren are just two examples that might be constituted as deviant because they involve perceptions of nepotism and dishonesty, at least from an outsider's perspective, clear violations of organizational norms.

Deviant Individuals in Relationships

A final way of viewing deviance is by focusing on the individual. From this perspective, any person devalued by society, regardless of behavioral rule violations, would be considered deviant. Examples could include persons living with HIV or with mental and physical disabilities. Deemed unworthy by society, individuals living with such health diagnoses or disabilities can be forced to exist on the margins of our society, seemingly forgotten and discarded. Individuals may also be considered deviant (rightly or wrongly) if their actions are deemed deviant. Gang members, a pimp and his prostitute, a john and a prostitute, a con artist and the conned, a cult leader and his or her followers, the homeless, or panhandlers are just a sampling of individuals who, because their behavior is unacceptable by society's norms, would be considered deviant. As a result, the plights of these individuals are typically ignored; they are often denied proper medical care and social assistance, and they are left to live a life of criminality. Yet interestingly, although society at large might shun them, many such individuals are able to

fulfill their belonging needs through their group membership. Thus, their connection to similar others becomes a vitally important part of their survival.

Research on deviance and relationships is complex, filled with a variety of theories that help researchers define and study nonnormative behavior, relationships, and individuals. This entry has only skimmed the surface by briefly reviewing the different ways in which deviance can be defined and enacted in relationships. Understanding deviance in relationships sheds light on how and why some individuals are victimized, exploited, and discriminated against and how some individuals may find a sense of belonging to deviant groups. Because deviance is a fluid, social construction, certain relationships, behaviors, and individuals that are considered deviant today may not be in 5, 10, or 20 years. For instance, cohabitation, considered deviant 50 years ago, is considered normal by today's standards. Recognizing the fluidity of deviance can help create a more inclusive, less prejudicial world. It is equally important to acknowledge the underlying power dynamics related to the labeling of deviance and deviant behavior. Specifically, as a result of the influence that dominant power structures (e.g., government, family, religion) have in U.S. society, some behavior is defined as deviant, while other comparable behavior may not be because it is enacted by those who possess more social and political power. All of these issues make the study of deviance in human relationships a fluid and socially relevant enterprise.

DIALECTICAL PROCESSES

The term *dialectical processes* refers to the contradictions that arise among a variety of opposing forces when people relate. Some researchers view these opposing forces as competing motivations within individuals. One example of opposing motivational forces is the desire to be open and honest with others versus the desire to be more guarded and less forthcoming in sharing information. Other dialectical scholars, especially those from the communication discipline, locate the opposing forces in the communication between relating parties. Leslie Baxter and Barbara Montgomery articulated Relational Dialectics Theory (RDT) in 1996 to understand these communicative tensions between opposing systems of meaning. From a communication perspective, the issue at stake is how contradictory meanings are negotiated between relationship parties.

Several contradictions emerge consistently in the dialectically oriented research. One of the most common is labeled a variety of ways, including separation-integration, autonomy-connection, or independent-interdependent. When parties negotiate their close relationships, they construct a meaning of closeness that struggles with the tension of individual autonomy (the expectation that parties will respect one another's individuality and freedom of action) and interdependent connection (the expectation that the parties will privilege the interdependence of their connection above their individuality). The reason this contradiction is so prevalent in contemporary American relating is that the culture has contradictory ideologies that coexist. The cultural ideology of individualism supports a meaning of closeness that emphasizes the needs and desires of the individual parties. According to this cultural view, close relationships are expected to preserve each party's identity as an autonomous self, granting each person freedom of action and positioning the relationship at the service of individual wants and needs. By contrast, the opposing cultural ideology of community supports a meaning of closeness in which individuality is trumped by a commitment to the other party and to the relationship above the individual needs of the parties. According to this competing view, individual needs are secondary to the needs of the

relationship and one's partner. This contradiction in what it means to be in a close relationship takes a variety of specific forms depending on the particular kind of relationship and where the relationship is in its developmental course. The contradiction of separation-integration could surface, for example, as a struggle over how much time to spend together versus how much time partners are granted to fulfill obligations outside of the relationship. It could also surface as a struggle over identity: to what extent parties are allowed to establish a self-identity independent of being half of a couple. The contradiction could surface, as well, in how much time the pair spends alone in couple time versus how much time they spend as a couple with others in their social network.

A second contradiction that also surfaces in much research goes by many labels expression-nonexpression, openness-closedness, and candor-discretion. At its core, this contradiction involves what it means to be communicatively open in the relationship. The frequency with which this contradiction surfaces among Americans is probably the result, once again, of competing cultural ideologies. On the one hand, Americans are immersed in an ideology of privacy, with the expectation that individuals have a right to privacy in their relationships and are entitled to avoid topics, keep secrets, and display discretion in what they tell their partner. On the other hand, Americans swim in a cultural ideology of expression in which individuals are accorded the right to say whatever they want, combined with a cultural ideology of intimacy in which total disclosure is an expectation of closeness. Parties negotiate what closeness means in their relationship by managing the struggle between candor and discretion. They also negotiate this struggle as a couple when they face the issue of how much to share about their relationship with outside third parties: What is private between the two of them and what can and should be shared with others?

A third contradiction that frequently appears in the research also goes by a variety of labels, including past-present, predictability-novelty, certainty-uncertainty, or reproduction-production. On one hand, after their first encounter, relationship parties are never without a relational history. The next time they meet, they inherit this definition from the past, which affords predictability

and certainty. On the other hand, however, parties can never reproduce their past completely; they are slightly different people, and the circumstances have altered at least somewhat. Even if the parties could reproduce the past meaning of their relationship, this would prevent novelty, creativity, and change. Thus, the meaning of the relationship is always to some extent up for grabs whenever parties communicate with one another. Sometimes, parties negotiate dramatic changes in the meaning of their relationship, often brought about by grappling with other dialectical contradictions that are circulating in the relationship. These dramatic changes often function as turning points that can alter relational meanings in profound ways. For example, among newly formed stepfamilies, especially among stepchildren, a dialectical struggle is often experienced between the meaning of the old family of origin and the new stepfamily, with efforts to define the new stepfamily often regarded as a threat to the memory of the old family of origin. A second example might be divorced parents, whose negative marital relationship is a meaning system that could work against a constructive coparenting relationship needed in order to raise their children.

A fourth contradiction that often surfaces in relationships is variously called self-other or similarity-difference. Researchers have long documented the meaning that partners give to the perception of similarity between them; it signifies a validation of oneself, communicative ease between partners, and freedom from conflict. However, if partners are too similar to one another, they do not help each other to grow; selves grow to the extent that they are different and can expose one another to different perspectives, experiences, and so forth. Difference is a source of stimulation, excitement, and growth. But it also can mean an increase in unpleasant conflict.

A fifth contradiction that frequents relationship parties is referred to as the ideal-real. This contradiction is evaluative, as parties attach good and bad meanings to their relational practices in comparison with what they perceive to be the ideal. Sometimes, the real—the meanings of what the parties perceive as their reality—match the ideal. Often, however, there are discrepancies and hence struggles of evaluation. In anticipating evaluations by outsiders in which a pair's relational practices

are judged against an ideal, partners often engage in account-giving efforts. For example, imagine a young married woman who says to her family, "I know you guys want grandchildren, but we've decided to remain childless. It's our life, not yours." This account calls up the ideology of individualism to justify an anticipated negative evaluation from family members in the couple's decision to deviate from the normative cultural script for married couples to have children.

The variety of contradictions experienced by relationship partners is substantial, and dialectical researchers argue for the importance of appreciating the unique contradictions that face given relationship partners. To date, dialectical processes have been identified in a variety of relationship types in the United States, including dating relationships, divorced pairs, employee relationships, marital couples, marital couples in which one partner has been diagnosed with dementia, marital couples transitioning to parenthood, members of abusive relationships, mother-daughter relationships, older dating partners, parent-child relationships, platonic friendships, retirement-home relationships, romantic pairs, and stepfamily relationships. Contradictions vary by culture as well. Relationships in collectivist societies, for example, are not animated by the ideology of individualism the way mainstream Americans are when they relate; thus, the separation-integration contradiction doubtless is experienced entirely differently, if at all, by pairs in collectivist societies.

Relational partners jointly act in ways that negotiate the interplay of contradictory oppositions. Sometimes partners act in the moment to center one system of meaning, thereby marginalizing or silencing competing systems of meaning. The couple who acts to give priority to their relationship over each party's individual competing demands for time from work, school, other family obligations, and so forth is centering connection in the meaning of their relationships while marginalizing autonomy. If they repeat this same prioritization over time, they have positioned connection as an authoritative meaning in their relationship. Alternatively, the pair could move back and forth between decisions to emphasize their relationship versus decisions to be responsive to individual demands for time and resources. One week, job demands might take priority while a relationship takes a secondary

priority; next week, however, the couple might privilege the value attached to the relationship and take a 3-day getaway weekend. The relationship parties could also enact compromises, giving partial attention to all relational and nonrelational demands on them. In addition, the parties could reframe what it means to prioritize the relationship, moving beyond either-or thinking. For example, a pair might agree that putting in overtime at work is a way to prioritize the relationship because it goes into saving for the down payment on a house. In this way, work demands and relationship demands are reframed in a manner that is not viewed as competitive by the parties. Rituals have been identified as an especially important communicative practice in which relationship partners reframe opposing meanings so that they all are honored. For example, the remarriage ceremony of an older married couple celebrates both the uniqueness of their marriage as well as the fact that marriage is a conventionalized social institution.

According to RDT, relationship satisfaction is linked to how a pair navigates dialectical processes rather than the presence of contradictions per se. Dialectical processes are ongoing, and parties are continually interacting in ways that navigate the salient struggles of the moment. Thus, dialectical processes are normal for relating parties, although they require effort for parties to negotiate them. In fact, many of the conflicts experienced by relationship parties often involve disagreements over basic contradictions such as those discussed in this entry. It is through navigating dialectical processes that relationship parties create the possibility for change in their relationships.

Researchers who study dialectical processes use both quantitative methods (often surveys) and qualitative methods. Most of the work has employed qualitative methods in which the talk of relationship parties (both in interviews and naturally occurring between partners) is analyzed thematically for the presence of competing discourses, a method known as contrapuntal discourse analysis.

DISABILITIES, CHRONIC ILLNESS, AND RELATIONSHIP FUNCTIONING

Most long-lasting relationships with family and friends are touched by health issues. Illness and disability contribute to some of the most stressful life circumstances that individuals and relationships encounter. Accounts of coping with illness and disability in the context of relationships are often provided in popular media, particularly of families and couples coping with cancer, Alzheimer's disease, and HIV/AIDS. Illness and disability as a result of these illnesses and others such as diabetes, depression, cardiovascular disease, and respiratory problems, affect social roles, future hopes and dreams, and companionate activities of everyday life: work, leisure, sex, and social support. Although challenging, the results are not always negative, as might be presumed.

This entry provides an overview of human relationships in the context of illness and disabilities, including the types of questions one might ask about relationships and illness, general findings of research of illness impacts on relationships and relationship impacts on illness and disability, relationship theory, and promising approaches to support relationships through this challenging experience.

The Growing Presence of Illness and Disability in Human Relationships

The gift of longevity has guaranteed a prominent place for chronic illness now and into the future. In the past, people lived shorter lives due to poor public health, infectious disease, accidents, and wars. There was also a high mortality rate from cardiovascular disease, respiratory conditions, and other illnesses.

Chronic illness is currently the main cause of both death and disability worldwide. Of the 58 million deaths that occurred in 2005, approximately 35 million, or 60 percent, were due to chronic, disabling health problems, primarily cardiovascular disease, diabetes, cancer, and respiratory conditions. People are living longer, but they are living longer with health problems and disabilities.

The extent of people worldwide living with chronic conditions is significant; for example, the number of people over age 80 in Western Europe has quadrupled in the past 60 years. Of the 17 million people currently living with long-term conditions in Britain, up to 80 percent need support for self-care.

A substantial proportion of care is provided within the context of family and intimate relationships. It is important to note that those in the most disadvantaged socioeconomic groups experience the highest prevalence, mortality, and morbidity (ongoing health issues and disability), and the gap in health inequalities across the globe has been widening. Furthermore, those in disadvantaged groups are less likely to experience equality of access to services and support in regard to their health and social care needs. This circumstance can increase stress and burden of care for disadvantaged individuals and their families and can contribute to social isolation. Physical inaccessibility of housing and lack of transportation are some of the practical issues faced in sustaining relationships.

There are numerous relevant themes to consider in examining the interface between illness and relationships: the impact of illness and disability on relationships, how people adapt relationships in the context of illness, relationship theory, and specific relationship functioning (couples, parent-child, health professional), the impact of relationships on coping with illness, and approaches (policies and

practices) to improve relationship quality. In many instances, researchers are expanding beyond middle class, Western relationships to study these themes as they are experienced in different cultures, geographies, and socioeconomic contexts—for example, families coping with AIDS in Africa, inner-city couples dealing with a spinal cord injury as a result of violence, serious health problems in uninsured immigrant families, and so on.

Many of these issues have been studied both quantitatively (e.g., self-report measures on relationship quality, laboratory research on the effects of stigma) to examine theories and population characteristics and qualitatively (e.g., observations, personal accounts, focus groups) to capture richness and detail about the relationship-illness experience. The research literature is filled with studies of network, marital, and family functioning, as well as detailed accounts of the experience of illness, including relationship threats and resilience.

Impact of Illness and Disability on Relationships

How do illness and disability affect relationships? Surprisingly, there are many similarities in impact across a large diversity of health problems. Changes are reported to occur in both relationship quality and social network characteristics such as size and density (i.e., the level of interconnectedness of network members) of the network. Persons with chronic illness and disabilities tend to have smaller social networks with greater density. Relationships with family and health professionals are often core elements. If mobility and energy have been reduced, network members often live close by, and the variety of companionate activities is reduced. Many of these changes are initiated by the person with the health problem to preserve energy and reduce fatigue. Furthermore, the relationships of family caregivers are substantially affected when they are involved in extensive, day-to-day caregiving. The demands of care reduce caregivers' opportunities to get out into the community, socialize, and maintain their own relationships.

Studies have shown that divorce rates increase as a function of chronic illness and disability, primarily in younger couples in their 20s and 30s.

Loneliness and social isolation often increase with illness and disability and sometimes result from what seem like minor changes to functioning. For instance, recent studies of minor stroke often result in substantial lifestyle and relationship impacts. Overall, there is a higher than average depression rate in both individuals who have had a stroke and their family caregivers. The same is true in caregivers of family members with dementia.

Illnesses that have a neurological and behavioral component such as acquired brain injury, stroke, dementia, and similar neurological conditions may result in personality and relational changes that are known to cause significant challenges to the relationship, frequently because of their long duration, unpredictability, and the losses associated with such changes. Such alterations in functioning require considerable adaptations on the part of family members. These alterations involve not only the acquisition of new social roles that may have previously been carried out, but also, and of particular importance, emotional adjustment to perceived loss of valued aspects of the relationship, such as shared hobbies such as dancing or travel. Inevitably, some families may be better able to manage this change than others. In some circumstances, these changes can result in relationship breakdown within families.

There are also issues of social stigma, which in the case of such illnesses as dementia and schizophrenia, can lead to marginalization within the person's and families' community. With illness and disability, there are frequently issues of social stigma combined with caregiver burnout. These situations can sometimes include abuse and in some rare cases, murder of the ill person by family members. For instance, older adults with dementia are sometimes killed in Africa because they are viewed as bad luck and they consume scarce resources. Overall, studies of support services for family caregivers in most regions of the world and for most illnesses and disabilities are reported as inadequate.

Interestingly, many studies and accounts suggest that the experience of serious illness can also be perceived as improving relationships. For example, men sometimes report that caregiving had widened their horizons and helped them to grow. Furthermore, recent studies have focused upon the means through which families and couples work to

maintain their preexisting relationship. Couples made considerable efforts to sustain their relationship in the context of a diagnosis of dementia. Unhappy relationship situations are more likely to be terminated with the reassessment of life priorities that is reported with the presence of chronic illness. However, individuals sometimes feel forced to stay in unsatisfactory relationships as a result of guilt, finances, and high support needs. Illness opens a Pandora's Box in relationships, exposing characteristics of individuals and of their relationships that may have been present but not addressed, such as willingness to provide social and practical support or conflicting values about commitment in tough times.

Despite some consistencies in the effects of illness, individual, relational illness, and contextual (e.g., culture) characteristics, all influence relationship quality. Characteristics of the illness, such as physical, social, cognitive, and emotional characteristics, are important. A key element is illness course. Is the course of the condition stable, uncertain, or degenerative? Is one's mate or friend going to become sicker, more disabled, or die? Companionate activity, how mates and friends spend time together, is an important factor in relationship quality and the potential for change due to illness. For instance, couples who place a high value on travel and must now severely limit these activities due to treatment or disability will need to make substantial adjustments as compared to couples whose companionate activity is not particularly affected by the illness.

Impact of Relationships on Adaptation to Illness

Relationships with family and friends are important determinants of how an individual copes with illness and disability. On the positive side, emotional and instrumental support can be helpful, but there is a potential dark side when friends and family hindered rather than helped. Often people are present and supportive early on, but as an illness drags on, their presence and offers of support tend to diminish. Many people resist receiving support, either to maintain their personal sense of autonomy or to preserve the balance of give-and-take in the relationship. Indeed, preservation of

baseline levels of functioning in couple relationships may take priority over a willingness to admit that change has occurred. As a result, the true extent of a couple's difficulties may not be exposed until a serious challenge is experienced (e.g., death of a spouse). Such issues as stigma and fear of long-term consequences may be motivating factors behind the reluctance to acknowledge the need for assistance. Social support, both emotional and instrumental support, increases, and as a result, concerns regarding the balance of reciprocity within relationships can exist. Loneliness, often caused by feelings of social inadequacy and physical isolation, can be a barrier to self-care and physical recovery. Communal coping (how people cope together) is an important element in coping.

Human Relationships Theories

Several theories of human relationships are useful in understanding the impact of illness. For instance, social support, exchange and equity theories can be used to examine the provisions of relationships in the experience of illness, give-and-take, and fairness. Communal coping theory can offer explanations for how people in their relationships cope together (or alone) with illness. Attachment Theory can contribute understanding of individual styles of responding to major life crises and of the extent to which people rely on partners and friends for assistance. Communication theory can be useful in examining verbal and nonverbal communication about illness and its effect within couple and family relationships and within the broader social world. Finally, theories of attribution processes and social cognition can contribute to understanding how people conceptualize and explain relationship issues or changes as a result of illness and disability.

Interventions to Improve Relationship Functioning

There is considerable agreement among health leaders that the challenge for society, now and into the future, is how to reduce preventable illness and the preventable distress of illness and disability. Research has consistently demonstrated inadequacies in health and social service systems

in addressing the full range of illness-related social and psychological issues. Relationship functioning is an important but often overlooked issue. There is a need to create a more supportive family, community, and service environment for individuals with the health problems and for people dealing with a relationship partner's illness. Clarity for action can be built upon the strong foundation that has been developed in research and theory about both human relationships and adaptation in illness and disability. Although numerous studies have identified relationship problems, more clinical and intervention research is needed to develop and test efficacious strategies. Knowledge translated from such relationships and illness research could lead to improvements in service and policy. Clinical and community approaches involve couple therapy and support-group interventions focused on relationships and illness. Policy interventions that affect relationship quality can include addressing social issues such as housing, transportation, and improvements to physical and social accessibility of public facilities. These interventions should include health professionals (psychologists, social workers, family therapists) who can assess and address relationship problems. Sharing stories and strategies over the Internet and in self-help documents can also be useful. How individuals with illness and disability use the Internet and cell phones for everyday communication is a new and promising area for research and intervention.

DISCIPLINE IN FAMILIES

A broad definition of discipline, which derives from the Latin *disciplinare*, or to teach, would encompass the whole of socialization, the process by which children develop values and capacities for self-regulation, self-direction, and competence. More narrowly, discipline refers to the training of children with the purpose of fostering some form of correspondence or conformity to the requirements of parental authorities.

Prior to the 1970s, research on discipline was guided by an implicit unilateral framework of assumptions. Parents were considered to be active causal agents, and influence was assumed to flow in a unidirectional manner from parent to child. Children were considered to be passive recipients

of parental influence, and their resistance or failure to conform was interpreted as deviance. Moreover, research tended to ignore the larger context in which discipline occurred. For instance, parents and children were considered interacting as separate individuals rather than in an interdependent relationship context, and the meaning of the interactions for parents or children was disregarded. Thus, research on socialization tended to focus on correlations between isolated parenting techniques and presumed outcomes such as children's compliance or values and transformed a dynamic long-term interactive process into a one-sided analysis of isolated parenting techniques. The prototypical example of a unilateral perspective is traditional authoritarianism, according to which discipline is equated with parental application of force, including corporal punishment, in order to obtain the child's compliance with the parent's directives.

In recent decades, research on socialization has increasingly incorporated a bilateral perspective where parental influence occurs in a relationship context in which children also contribute their own influences. The four contemporary perspectives on parental discipline and children's conformity that are reviewed in this entry show an increasing integration of several assumptions. These assumptions include that the ideas that influence between parents and children is inherently bidirectional, that parents and children are equally active agents, and that the dynamics of parent-child interactions take place in a distinctive long-term interdependent relationship context.

Behavioral Perspective

The behavioral perspective on discipline and conformity has conceptual roots in operant theory and functional analysis of behavior, which emphasize the study of parent-child interaction in terms of immediate observable contingencies between antecedents and consequences as causes of behavior. A trademark of the behavioral perspective is that it avoids the inference of mental constructs such as the relationship, the meaning of parent and child behaviors and goals and motives in analyzing parent-child interactions. In addition, the behavioral perspective was shaped by clinical research on children with conduct disorders whose

presenting problems include severe noncompliance. The Coercive Process Model, which provides a rationale for behavioral interventions, focused on parental failures to manage children's noncompliant behavior as the primary cause of children's aggression and other forms of deviance. The model proposes that parental mishandling of ordinary acts of noncompliance during early childhood may become part of a causally interconnected chain of mutually aversive behaviors that escalate in the context of the family interactions and lead to the child's involvement in antisocial behavior throughout development. Behavioral interventions in families of noncompliant children are designed to train parents to manage children's behavior by the effective application of external contingencies. Critical skills include identifying children's noncompliant behaviors; monitoring children's behavior outside the home; providing clear, direct, and forceful commands and administering contingent rewards for compliance; and contingent but noncoercive punishment such as time-out or work chores for noncompliance.

Contemporary behavioral perspectives consider bidirectional influence in the sense that noncompliance contributes to the dynamics of coercive family interactions and to impairments in parents' ability to manage their children's behavior. However, parents are emphasized as the critical agents of change in interactions involving discipline with children considered in a reactive role. Moreover, there is little consideration of the importance of relationship context or relationship variables that affect the dynamics of disciplinary interactions.

Self-Determination Theory

Self-Determination Theory derives from longstanding internalization perspectives, which emphasize children's development of internal motivations for conformity as crucial in socialization. Self-Determination Theory assumes that people are active organisms, with innate tendencies toward psychological growth and development, who strive to integrate their experiences into a coherent sense of self. Children are considered to be reflective, self-determining agents capable of judging the motivational origins of their

own actions and who act on the environment with a sense of choice. Parents are important in this process because their actions for guiding or controlling children's behavior can either support or undermine their natural tendencies toward active engagement and psychological growth. Common with earlier internalization perspectives, Self-Determination Theory assumes that children have various motives for complying with parental directives, the most important distinction being between external control or mere compliance and self-accepted internal control. Various motivational systems have been proposed as sources of children's internal control including guilt, empathy, and sense of autonomy. In Self-Determination Theory, it is argued that internal motives themselves have intrapsychic counterparts to internal and external motivation so that children can experience their conforming behavior as constraint or autonomous choice.

Internalization theories emphasize parenting behaviors employing minimal use of coercive power, reasoning, and autonomy support as a way of promoting internal control of conformity. According to Self-Determination Theory, three types of parental practices, including autonomy support (gentle control, provision of appropriate choice), structure or clear expectations, and caring interpersonal involvement, are important in facilitating children's development of an integrated and self-accepted internalization of self-regulation.

Regarding contemporary theoretical assumptions, Self-Determination Theory acknowledges children's agentic motives as key, and parents are encouraged to engage in practices that support children agency. However, most of this literature focuses on dimensional approaches to measuring parental behavior and the parent-child relationship rather than the dynamics of parent-child interaction. Although bidirectional effects are recognized, there is little research on the interactive processes by which these come about.

Contextual Perspectives

Behavioral theory and Self-Determination Theory consider parental discipline practices in terms of uniform, trait-like strategies, or dimensions, and implicitly ignore the role of context as a factor in

determining parental choice of strategy or children's responses to parental requests. However, researchers have long advocated a contextual approach to discipline where socialization experiences and self-regulation are considered to occur within specific situational contexts or qualitatively different social domains that have different requirements and follow different principles of parent-child relationships.

As an example of a situational approach, the argument is that individuals interpret the meaning of different situations that they encounter in their everyday lives and behave accordingly to the standards of conformity that are appropriate for each situation. Depending on the specific situation, a socially competent person may exhibit conformity to rules and expectations using the varying standards of exact immediate compliance, durable internal control in the absence of surveillance, or a more flexible standard of conformity consisting of negotiation and accommodation within close relationships. Studies have found that parental disciplinary choices have been highly situation specific, with parents choosing between ignoring, negotiation, power assertion, and reasoning depending on the nature of the misdeed. Moreover, different standards of children's conformity are accepted by parents as appropriate depending on the meaning of the situation. Social Domain Theory in particular has identified qualitatively different meanings that parents and children ascribe to situations, including moral, conventional, prudential and personal issues, which determine parental disciplinary choices and children's acceptance or resistance to parental pressures to conform.

Another contextual perspective considers socialization domains at a higher level of analysis. In this perspective, socialization is organized within larger domains that are activated at different times during socialization. Four domains have been proposed: protective caregiving, control-authority, group identification, and mutual reciprocity. In essence, each domain constitutes a different but complementary route to socialization with different principles for optimal interaction, somewhat different outcomes, and requiring different parenting practices.

Contextual perspectives provide a more complex and dynamic view of discipline in the parent-child relationship than the external control and

internalization perspectives. In terms of theoretical assumptions, contextual theories acknowledge bidirectional processes in that it is generally some characteristic of the child or the child's misdeed that activates parental behavior. However, although children's autonomy motives are considered, most theories emphasize parents' interpretations of situations. The essence of parental competence is the ability to adapt their mode of functioning to meet the requirements of different situations. This can be achieved more successfully if parents can accurately perceive their children's point of view or appropriately interpret the meaning of children's transgressions and tailor their interventions accordingly.

Social Relational Theory

Social Relational Theory emphasizes that socialization and the dynamics of parent-child interactions should be understood as occurring in the context of close personal relationships. In earlier research, dimensions of parent-child relationships such as parental acceptance, nurturance, involvement, and warmth were considered as background variables that enhanced the effectiveness of parental discipline practices. Recent relational perspectives propose that parent-child relationships rather than parental discipline strategies are the foundation for successful socialization. Parenting that contributes to the formation and maintenance of relationships characterized by mutual responsivity and reciprocity provides the early foundation of children's cooperation with parental requests and demands. Links between children's early compliance and measures such as secure attachment, positive affect, and responsive parental behavior in nondisciplinary contexts provide evidence for this view.

Particular to social relational perspective is a focus on the process of parent-child interactions and especially on the contribution of the relationship context to interaction dynamics between parents and children. Processes having to do with bidirectional influence and the experience of agency and exercise of power depend on the relationship context. Critical sources of dynamics include interacting on the foundation of expectancies developed in the prior history of the relationship, future anticipations that consider the effects of current

disciplinary choices on long-term outcomes or the future of the relationship, and the mutual interdependence of the needs and goals of both parents and children. Children's agency and autonomy is enabled by the relationship that is a source of both parental receptivity and vulnerability to the influence of children. Social Relational Theory is based on a dialectical conception of bidirectional influence where parents and children as human agents have capacities for interpreting the meaning of each others' behavior and for anticipating and adjusting to each others actions. Although parents and children have different needs, goals, and strategies, they are nevertheless embedded in an interdependent relationship that constrains their actions.

The relationship context helps to explain numerous bidirectional phenomena of family life, including parental receptivity to children's influence, mutual cooperation, negotiation, conflict, ambivalence, and parental tolerance of appropriate forms of resistance in their children. For both parent and child, the competent expression of agency involves accommodating to the mutual constraints of a reciprocal relationship. Whereas in earlier perspectives on discipline, the focus was on parents' management of power struggles so as to effectively force or persuade children to comply with parental commands, in the relational perspective, the primary focus is on the formation and management of the long-term relationship, a function that places constraints on the parent's use of coercive power.

In conclusion, contemporary theory on discipline is marked by an increased interest in the process of socialization, context, and a progressive integration of assumptions of bidirectional influence, the agency of parents and children, and the centrality of the parent-child relationship for understanding the processes and outcomes of socialization. An important problem is the translation of these scientific insights into applied perspectives and clinical interventions that often remain unidirectional and acontextual. However, there are signs of change. Guidelines for the effective use of discipline published by the American Academy of Pediatrics reflect a developmental perspective and places traditional concerns regarding compliance and internalization within a relationship system. It suggests that an effective approach

to discipline must contain three elements: a learning environment characterized by positive, supportive parent–child relationships; a proactive strategy for systematic teaching and strengthening of desired behaviors; and a reactive strategy for decreasing or eliminating undesired behaviors. New clinical interventions for conduct disorders are based on a synthesis of behavioral and developmental research on discipline and parent–child relationships. These propose that child misbehavior cannot be evaluated apart from the overall quality and sustainability of the parent–child relationship. Thus, relationship management is added to behavior management as a locus for change in maladaptive disciplinary practices.

DISCOURSE ANALYSIS

Discourse analysis is an umbrella term for a range of methodological approaches that analyze the use and functions of talk and text within social interaction. These approaches are used across social science disciplines such as psychology, sociology, linguistics, anthropology, and communication studies. Discourse analysis is interdisciplinary in nature, developed from work within speech act theory, ethnomethodology, and semiology as well as post-structuralist theorists such as Michel Foucault and Jacques Derrida and the late works of philosopher Ludwig Wittgenstein. Discourse analysis approaches are crucial for understanding human relationships because they focus primarily on interaction: How people talk to each other and the discursive practices (talking, writing) through which relationships develop, fall apart, and so on. This entry covers central features of discourse analysis, methodological issues, and some of the most commonly used versions of discourse analysis.

Common Features of Discourse Analytical Approaches

Discourse analysis approaches combine a set of theoretical assumptions about what discourse is and how it is used with a rigorous methodology that determines what kind of data are appropriate and how they should be analyzed. The distinctions between different versions of discourse analysis have led to many heated debates within the field, particularly where researchers are working within a specific discipline (such as psychology).

There are, however, underlying commonalities across discourse analysis approaches. First, most theorists agree that discourse—all forms of talk and text (and for some researchers, this includes bodily movements or eye gaze within social interaction)—is central to everyday life and thus, to human relationships. The term *discourse* is commonly used to highlight the focus on language use rather than grammatical or linguistic features.

The second area of commonality is the assumption that discourse is social action, that social practices are performed in and through discourse. This is seen in three ways. First, discourse is treated as constructing or constituting the world. That is, discourse does not merely reflect reality; rather, it constructs reality in particular ways. When people describe the world, they are thus building up a certain picture of the world (or person, for instance) that is open to challenge, collusion, or negotiation. This is a crucial departure from many linguistic and communication theories, which argue that language is a passive medium (or conduit or pipeline) through which ideas, thoughts, and so on are accessed.

Second, social action is also produced through there being many versions of the world that can be constructed in discourse. That is, if people assume discourse constructs reality, then it follows that different discourses construct reality in different ways. For example, newspapers may report on the same event, but the story is different each time. There is thus variability in talk and text, as discourse is produced in different contexts and for different functions; hence, as the function or context changes, so does the discourse. Discourse analysts argue, to a greater or lesser extent, that each version is as true as any other, that people cannot objectively claim to know the real version of events. Reality may thus be regarded as a series of multiple realities, each of which are brought to life through various discursive practices. It is within this area that there is much cause for dispute among discourse analysts, as some argue that to make a relativist claim (that there is not one truth but many truths) means that one cannot then state which version of the truth is the right or correct one. Those who take a more realist line (that there is an underlying truth behind discourse), however, claim to be able to take a political stance (a point of view or perspective) on an issue.

The final way in which social action is produced is through the coproduction of meaning within discourse. As discourse constructs reality or realities, the location of meaning making is treated not as an individual product (e.g., of how someone thinks) but as the product of social interaction. A helpful analogy here is to imagine the visual illusion that flips between being two heads (sideways on, facing each other) and being a vase. Meaning, it is argued, is created in the space between people (the vase) rather than within the people (heads) themselves. What people mean by a statement is thus not a matter of what they thought about when they said it, but how the words are interpreted and responded to by others. For example, whether or not a partner claims to love oneself is not about their intentions or feelings but about how they say it and how this statement functions in the interaction. This means that discourse must be understood within a historical, social, and cultural context. Again, there are differences of opinion as to how context should be defined: as only the words that people say (and how they say them); whether issues such as age, gender, and ethnicity should be defined; or as broader historical or cultural contexts.

Using Discourse Analysis as a Method

The social constructionist basis of most forms of discourse analysis means that it cannot simply be used as an interchangeable method within research (as if it were another tool in the toolbox of methods). This is because, as noted above, it requires the researcher to buy into certain theoretical assumptions: that discourse constructs reality and that context is fundamental to understanding discourse in any human relationship. That aside, the steps for acquiring and using discourse analysis are broadly similar, though they are by no means a straightforward recipe in terms of analysis.

Discourse analysis research involves the audio or video recording of social interaction (e.g., telephone conversations or family mealtimes) or the collecting together of textual documents (e.g., personal diaries or health promotion literature). A large corpus of data is accumulated on a particular topic. Data collection is guided by a research question(s) in a topic area. For instance, an interest

in the negotiation of household tasks within a relationship might lead to the collection of either interviews with couples or families who live together or the video recording of the family as they discuss tasks over the dinner table. If audio or video data are used, a written transcript (i.e., a word processed copy of the talk) is produced to be analyzed alongside the audio or video files and to be used to report findings in publications.

The data corpus is then coded by searching for recurring patterns, themes, or instances of a particular phenomenon. This process is guided by past research and the research question. The transcript will be read many times in order to get a feel for the data and to ensure that the initial stages of coding are as inclusive as possible. Continuing the example above, this might mean selecting those areas of talk where people seem to be in conflict or disagreement over duties. Analysis of the data then requires an in-depth examination of discursive devices such as use of pronouns, categories, or rhetorical features (where alternative versions of reality are directly or indirectly argued against). Styles of analysis vary greatly depending on which version of discourse analysis is being used from looking closely at the way in which people take turns in talk and how the sequential organization of interaction helps to construct the meaning of talk (discursive psychology) to considering the use of concepts such as synchronicity (the smooth coordination of people's talk) and shared ways of speaking (sociolinguistics and ethnographic approaches).

The resultant discourse analysis is often in the form of a set of themes and illustrative points that relate back to the research question. Extracts from the transcribed data are used to evidence the analytical points, enabling the reader to view the data directly and to decide for themselves about the veracity of the claims being made. As such, discourse analysis approaches are purely qualitative in method, but they are also extremely applied in that findings can be used to relate back directly to the setting in which the data was collected (or similar settings).

Versions of Discourse Analysis

The divergent roots of discourse analysis have led to many different varieties. Here, three strands are

outlined, along with more subtle variations within each, as these are most relevant for the study of human relationships.

Discursive psychology refers to a strand of discourse analysis that has emerged from the work of Derek Edwards and Jonathan Potter in the 1990s and develops Jonathan Potter and Margaret Wetherell's seminal work on discourse analysis in social psychology in 1987. This version examines how psychological concepts (such as emotions, attitudes, and beliefs) are constructed and understood in everyday interaction. This work is particularly suited to human relationships and has been used to examine, for example, marriage and family counseling sessions and family mealtime interaction. A slight variation on this approach is the discursive psychology developed by Rom Harré, which places more emphasis on cognitive processes (i.e., what people are thinking or mentally processing) and their role within talk. Edwards and Potter's version of discursive psychology is more agnostic about cognition. A third area within this branch of discourse analysis is that known as *critical discursive psychology*, which focuses on similar psychological notions but uses a broader notion of context, taking into account cultural and historical frameworks as well as the discourse itself. For instance, research by John Dixon and Margaret Wetherell examines issues of social justice and gender within talk about household labor.

A second major branch of discourse analysis is known as *critical discourse analysis*, which is based upon broadly Marxist principles: that some groups in society have more power than others and that oppression is mediated through discourse. Key theorists in this area are Norman Fairclough and Teun Van Dijk, and research has been carried out on topics where there is some level of inequality or abuses of power. It is this notion of power and of being critical (within discourse analysis, this is broadly used to refer to approaches that take a more realist perspective and thus can stake a claim about what version of the truth is more appropriate or acceptable than another) that is central to this version of discourse analysis. For instance, these approaches often focus on discourses around racism, sexism, or other perceived inequalities in society. There are strong similarities with *Foucauldian discourse*

analysis, which is routed in the work of philosopher Michel Foucault and which treats power as a more fluid concept. Here, power can be positive as well as negative, and it is closely connected with knowledge and discourse. Power is not something owned by groups through virtue of their ways of talking; it is flexible and can be used by individuals through use of different discourses and ways of representing others.

The third main strand of discourse analysis is characterized by approaches such as interactional sociolinguistics and the ethnography of speaking. These approaches take a broader perspective on context and are interested in areas such as interethnic communication, communicative styles (fixed ways of talking that are often associated with groups or communities of people) and the notion of speech genres, where talk is characterized by particular features and functions as a consequence of being associated with a particular area of communication (e.g., conversations between parents and children over mealtimes).

DISILLUSIONMENT IN MARRIAGE

Disillusionment is the decline in positive affect about and perceptions of the spouse and the marriage and a corresponding increase in negative affect about and perceptions of the partner and the marriage (e.g., feeling increasingly disappointed, bitter, and defeated; less close to the partner; and less fulfilled in the marriage). This entry outlines the theory on disillusionment in marriage, provides evidence of the prognostic value of disillusionment early in marriage for later marital instability, and traces its roots to spouses' idealization of one another and their relationship during courtship. It concludes by describing the Marital Disillusionment Scale that can be used to assess perceptions of disillusionment in marriage.

Theory on Disillusionment in Marriage

An important characteristic of courtship is the process of idealization. According to Willard Waller, partners see each other fairly realistically at the beginning of a dating relationship. As the relationship develops and partners' feelings for each other become deeper, however, dating partners increasingly feel a strong sense of enchantment and wish to display only some of their personality characteristics in order to live up to the images they believe the other partner may have of them. They also tend to focus on what they perceive to be their partner's virtues. As a result, they have mostly positive interactions with and develop favorable impressions of their partners' personality. Although dating partners are not necessarily unaware of each other's shortcomings, they often fail to realize what effect their partners' shortcomings may have in the future; rather, they focus their attention on the positive side of their partner and the good qualities of their courtship.

Once partners are married, however, and interdependence increases, spouses begin to engage less in impression management and generally become more aware of each other's true personality and character. Evidence of the partner's shortcomings inevitably begin to emerge. This lack of congruence between people's perceptions of their partner and the evidence of their partner's behavior is experienced

as threatening because it has the potential to undermine people's belief that their partner truly is the right person for them. Moreover, spouses' views of each other usually change and become less positive, setting them up for disillusionment.

Research on Disillusionment in Marriage

Research shows that disillusionment during the early years of marriage is of prognostic importance for later divorce. Two studies in particular demonstrate the significance of disappointment and disillusionment in marriage for subsequent divorce. Kim Buehlman and colleagues studied 52 married couples over a period of 3 years using an oral history interview as well as observational and physiological measures to predict marital stability. They found that spouses', especially husbands', disappointment in their marriage, as captured in the expression of depression, hopelessness, and defeat, was the single most powerful predictor of divorce 3 years later.

Ted Huston and his colleagues examined disillusionment early in marriage and its effect on marital stability. They found that disillusionment during the first 2 years of marriage, as reflected in (a) loss of love, (b) declines in affection, (c) decreases in one's perception of the partner as a responsive person, and (d) increases in feelings of ambivalence about the relationship, distinguished couples headed for divorce from those who stayed married.

Courtship Antecedents of Disillusionment in Marriage

Waller's Theory of Idealization during courtship, and subsequent disillusionment in marriage, has spurred interest and empirical research among social scientists. One of the earliest empirical studies examining the premarital predictors of disillusionment in marriage was conducted by Charles Hobart more than 50 years ago. He found support for the notion that men's premarital romanticism was associated with disillusionment early in marriage. More recently, Sylvia Niehuis and her colleagues systematically examined the courtship predictors of disillusionment early in marriage. Their research findings suggested two different

patterns of idealization during courtship, each one predicting disillusionment in marriage. Specifically, some premarital partners seemed to rush blindly into marriage, driven mostly by extremely passionate courtships. These partners fell in love with one another very quickly, engaged in premarital sex very soon, and early in the relationship felt certain of wanting to marry one another. They also had very short courtships that left little room for testing partners' differences and compatibility. Instead, premarital conflict and feelings of ambivalence seemed to add spice to their relationship. These couples may have experienced disillusionment early in marriage because of their discoveries about their partner and the quality of their relationship.

Other partners seemed to have been aware of problems in their premarital relationship as indicated by partners engaging in many relationship maintaining behaviors and dating each other for a very long time before they got married. These couples also had courtships characterized by very little passion. Partners took much longer to fall in love with each other, to have premarital sex for the first time, and to feel certain about wanting to marry one another. For these couples, a crushed hope of a better relationship after marriage may have been the primary reason for disillusionment early in marriage.

Assessing Disillusionment

Despite its importance for understanding marital instability, marital disillusionment has not received much attention from researchers. This is partly due to the lack of direct measurement. Disillusionment, by definition, is a process that occurs over time, and most researchers have used short- or long-term longitudinal designs to assess it; this approach requires much time, effort, and multiple points of measurement. Moreover, some have conceptualized disillusionment as changes in feelings for, behaviors toward, and perceptions about the partner rather than directly assessing participants' perceptions of disillusionment.

Niehuis and her colleagues developed the Marital Disillusionment Scale to provide a direct measure of perceived disillusionment that could be used in survey research. Disillusionment as assessed by their

scale encompasses both a decrease in perceived positive and an increase in perceived negative feelings, behaviors, and cognitions over time. The scale consists of 16 items (e.g., “Marriage was not at all what I had expected it to be; I felt very disappointed and bitter”; “I used to love spending time with my spouse, but then it started feeling like a chore”; “Before we got married, my spouse put his/her best foot forward; later he/she no longer bothered”) and has high internal consistency and high convergent, discriminant, and criterion validity.

DISPLAY RULES

Display rules is a term originally coined by Paul Ekman and Wallace V. Friesen, who used it to explain how people of different cultures manage their displays of emotion, depending on context. It refers to the rules, norms, guidelines, and expectations that people learn to manage and modify emotional displays depending on social circumstances. Display rules explain how individuals may alter and manage their emotional expressions depending on whom they are interacting with. Most people, for example, would readily express anger toward a younger sibling at home but would be more hesitant to do so toward their boss at work because they have learned a display rule not

to display such aggressive emotions toward people of higher status in that context. This entry discusses why display rules exist, how they work, and the cultural similarities and differences in them.

Why Do Display Rules Exist?
